THE DISPENSATORY
OF
THE UNITED STATES OF AMERICA

TWENTY-FIRST EDITION

THOROUGHLY REVISED, LARGELY REWRITTEN AND BASED UPON THE TENTH REVISION OF THE UNITED STATES PHARMACOPŒIA, NATIONAL FORMULARY FIFTH EDITION, AND THE BRITISH PHARMACOPŒIA 1914

BY

HORATIO C. WOOD, JR., M.D.

PROFESSOR OF PHARMACOLOGY AND THERAPEUTICS IN THE UNIVERSITY OF PENNSYLVANIA; PROFESSOR OF MATERIA MEDICA IN THE PHILADELPHIA COLLEGE OF PHARMACY AND SCIENCE; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

CHARLES H. LAWALL, PH.M., D.SC., PHAR.D.

PROFESSOR OF THEORY AND PRACTICE OF PHARMACY IN THE PHILADELPHIA COLLEGE OF PHARMACY AND SCIENCE; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

HEBER W. YOUNGKEN, PH.M., PH.D.

PROFESSOR OF BOTANY, PHARMACOGNOSY AND MATERIA MEDICA IN THE MASSACHUSETTS COLLEGE OF PHARMACY; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

JOHN F. ANDERSON, M.D.

DIRECTOR OF THE RESEARCH AND BIOLOGICAL LABORATORIES OF E. R. SQUIBB AND SON; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

IVOR GRIFFITH, PH.M.

ASSISTANT PROFESSOR IN PHARMACY IN THE PHILADELPHIA COLLEGE OF PHARMACY AND SCIENCE; DIRECTOR OF THE CLINICAL LABORATORY OF THE STETSON HOSPITAL

PHILADELPHIA AND LONDON
J. B. LIPPINCOTT COMPANY

Entered, according to Act of Congress, in the year 1877,
By George B. Wood, M.D.,
In the Office of the Librarian of Congress at Washington.

PREFACE.

The appearance of new revisions of both the United States Pharmacopœia and the National Formulary, as well as the many changes which have taken place in medical and pharmaceutical practice during the past decade, have necessitated an unusually extensive revision of this book.

While the general form and mode of presentation, the value of which have been so well established by the approval of the professions for many years, have not been departed from there are numerous changes to which attention may be directed. These alterations have been so great that large sections of the book have had to be completely rewritten. It may be remarked in this connection that the editors have spared no effort to bring the work abreast of the latest information concerning the subjects treated. Not only has advantage been taken of the numerous recent treatises in the various allied fields but thousands of articles, on specific topics, which have appeared in current journal literature of medicine and pharmacy have been utilized.

The U. S. Pharmacopœia X has admitted to official recognition 33 new drugs (not including preparations) some of which were practically unknown to the medical profession ten years ago. All of these, together with the recent admissions to the National Formulary, have been given thorough consideration. In addition a large number of other new remedial agents—some showing great promise of becoming of permanent value—have been introduced. These also have received careful attention—in Part II although not in quite so extensive detail as the official drugs.

The fact that the National Formulary is now a legal standard, on a parity with the Pharmacopœia in most parts of the country, has made it seem wise to include the drugs of that authority with the official substances in Part I, instead of in Part II as in previous editions of the Dispensatory. The galenical preparations of the N. F. are, however, described in summary in a separate place as heretofore.

For many years editors of the Dispensatory have been considerably disturbed by the continual increase in the size of the book, a growth which was threatening to make it too unwieldy to handle as a single volume. In the present edition a strenuous effort has been made to meet this situation by careful pruning and condensation. In the first place there has been a considerable elimination of repetition; for example, certain chemical constituents which occur in different plants, were, in previous editions, described in more or less detail in connection with several of the drugs in which they were found, whereas in the present edition their properties are set forth in detail only once and they are merely mentioned by name as principles present in the other plants in which they occur.

Much valuable space has also been saved by the omission of obsolete material, such as the discussions of chemical problems of past generations which are now solved, details of old formulas no longer employed, descriptions of abandoned methods of manufacture and similar topics which are chiefly of historical interest. In this pruning the editors have striven not to omit any information of real value, but to delete only those things which have been superceded by more modern knowledge or methods.

For the same reason it has been deemed wise to drop the translations of Metric into Apothecaries' measures and of Centigrade temperatures into Fahrenheit. In the preface of the Nineteenth edition of the Dispensatory the hope was expressed that the day was not far distant when the continuation of the duplex system of weights and measures would no longer be required. In the opinion of the present editors that day has arrived. Pharmacists, generally, are sufficiently acquainted with the internationally used Metric system —which has been for thirty years the only one recognized by the U. S. Pharmacopœia in its formulas—to make such translations unnecessary. Moreover any such translation to be even approximately accurate must be so cumbersome as to be of little real usefulness. In view of these facts it was felt that the space occupied could be more advantageously used for other purposes. Only in the case of doses was it deemed wise to continue double system. The great majority of American physicians are so firmly wedded to the Apothecaries' weights and measures, that practically all the prescriptions of the land are written in that system; and in a matter so intimately connected with the compounding of prescriptions as that of dosage it seems necessary to insert both quantities. It may be remarked in this connection that the equivalent doses given are not intended to be accurate translations, but merely to signify the ordinary limits which are employed by those who write in the Metric or in the English system respectively.

The references to the literature, which has been so conspicuous feature of past editions, we believe to be of much value in encouraging research and in aiding those who wish to find more detailed information concerning some special topic in which they may be peculiarly interested. Although many of the older references have been dropped the modern bibliography has been considerably extended. The aim of the editors has been not only to give the sources of the most recent studies in the fields of pharmacy and medicine but also to furnish, at least, the key which will unlock the door of the past to those who may wish to trace the history of the development of some phase of the subject. The same system of abbreviating the names of journals as was used in the 19th and 20th editions is continued.

In the cause of the more efficient utilization of the information of the Dispensatory we would urge the reader, especially one who may not be familiar with past editions, to a careful perusal of the *Introductory Matter* on page V; it not only explains the plan on which the book is constructed, but also gives certain definitions essential to an understanding of the text.

The editors desire to express their thanks to Mr. Ralph L. Calvert and Mr. Paul Card for their assistance in preparing the index.

It would not be fitting to let pass the occasion of a new edition of this old work without some mention of the editors who have gone from their labors since the last edition. Prof. Samuel P. Sadtler was for more than thirty years associated in the revising of the United States Dispensatory. His wide knowledge of chemistry, his long experience as a teacher and his high character had made him a well-known and highly respected authority. Prof. Henry Kraemer, who had charge of the botany and pharmacognosy in the last edition, brought to the work a breadth of knowledge and a scholarly spirit that made his contribution of great value to the whole profession. The achievements of both of these men will long rebound to the credit of pharmacy.

PREPARATIONS OF THE NATIONAL FORMULARY 1650
GENERAL INDEX 1691

EXPLANATORY INTRODUCTION.

That this work may be used to the best advantage there are certain matters of general information and concerning the scope of the book with which the reader should be acquainted.

General Arrangement.—The Dispensatory is divided into ~~to~~ three main divisions. In Part I are included all the drugs and preparations recognized by either the U. S. or British Pharmacopœias and all the crude drugs recognized by the National Formulary. These are arranged in alphabetical order according to their Latin titles.

In Part II are considered those substances not official in any of the above standards. These are arranged in alphabetical order according to their English names.

In Part III are included (1) General tests, Processes and Apparatus, Reagents Test Solutions and Tables of the U. S. Pharmacopœia. (2) The appendix of the British Pharmacopœia (3) a summary of the Galenical preparations of the National Formulary. (4) Formulas for reagents used in clinical examinations of the blood, urine, gastric contents etc. (5) Various tables showing the relative values of the Apothecaries, Troy and Imperial units, the size of drops of various liquids, and other subjects not included in the Pharmacopœial tables.

Arrangement of Part I.—In treating of the official substances an attempt is made to arrange the information according to the following order: The official titles and definitions; Unofficial synonyms; Source and history; Description and physical properties of the drug; Assay methods; Adulterants; Chemical constituents; Incompatibilities; Therapeutic uses; Toxicology; Dosage; List of official preparations. In a few cases it has been necessary to depart slightly from this order but the effort has been made to present the subject matter in a systematic manner so that it may be possible to find the answer to any specific question without reading the whole article.

General Tests.—Both the U. S. and British Pharmacopœias have adopted the plan of simply stating under the description of each drug that it does, or does not, "respond to the test for" this or that substance; instead of describing these identity tests over and over they are included in one place. These tests will be found in Part III of the Dispensatory. A similar condition holds for many of the Assay processes of the U. S. Pharmacopœia.

Constituents.—There are several chemical proximate principles which occur in a number of plants. In order to save space these are not described in detail in connection with each drug in which they are present but are simply mentioned by name and described in more detail under one or another title. For examples: Linalool is found in a number of volatile oils, its chemical formula and general properties are given once under the general article on *Olea Volatila;* the alkaloid berberine occurs in at least four official and several unofficial drugs, its detailed description is given in connection with the article on berberis. In those cases where cross reference to such descriptions may be lacking the interested reader should consult the Index.

We would also direct the attention to the following paragraphs from the "General Notices" of the U. S. P. as being essential to the interpretation of the official descriptions as quoted in this work:

U. S. Pharmaceutical Standards for Medicinal Substances.—"The standards of purity and strength prescribed in the monographs of this Pharmacopœia are intended to apply solely to substances which are used for medicinal purposes and when professedly bought, sold, or dispensed as such. Substances labeled with official synonyms must comply with the same standards, tests, and requirements that are demanded for the same substances under the official titles. Official preparations are to be made only from drugs that conform to the pharmacopœial standards, definitions, and descriptions.

"In the manufacture of products and preparations on a large scale deviation in detail from the official processes is permissible, provided the finished products conform to the definitions, descriptions, tests, and standards prescribed by the U. S. Pharmacopœia, Tenth. In the manufacture of pharmacopœia extracts and resins in which alcohol is used as a solvent only and does not remain in the finished product, it is permissible that alcohol made non-potable by the addition of from 5 to 10 per cent by volume of commercially pure methanol or of acetone be used in the place of ethyl alcohol in accordance with Federal Statutes and Regulations of the Internal Revenue Department, but the extracts and resins so made must be identical with those prepared by the processes in the monographs and must conform to the standards fixed by the tests of the U. S. Pharmacopœia, Tenth. This provision is not to be construed as permitting the use of specially denatured alcohol in the manufacture of any medicinal product other than extracts and resins." U. S.

Reagents.—"The reagents designated in this Pharmacopœia must conform to the standards established." (See *Reagents* Part III).

"*Moisture Tolerance.*—In most cases the allowable percentage of moisture in a chemical is specified in the monograph. When not specified, 5 per cent. of moisture is permitted, provided the chemical is dispensed in a condition of sensible dryness. For certain efflorescent chemicals, a limit of tolerance for loss of water of crystallization has been adopted analogous to the purity rubric described above.

"*Time Limitations.*—In testing chemicals for innocuous impurities in this Pharmacopœia (*chloride, sulphate, etc.*), it is understood that five minutes shall be allowed for the reaction to be observed unless otherwise specified. In the test for carbonizable impurities where sulphuric acid is used, it is understood that the time for observation is limited to fifteen minutes unless otherwise specified.

"*Solubilities.*—Solubility statements in the monographs are not intended as physical constants in the strict sense of this term, but primarily as information required by physicians and pharmacists in connection with the preparation and dispensing of medicines, except in the case of volatile oils where solubilities in alcohol of different strengths are used as tests for purity. For further statements concerning solubilities, see page 1547.

"Official chemicals, when brought into solution, may show slight mechanical impurities such as fragments of filter paper, fiber, and dust particles, unless excluded by definite tests in the monograph.

"*Melting, Boiling and Congealing Points.*—The figures given for these constants have been determined by the official methods and in estimating the physical constants of official products the pharmacopœial processes only are to be used. Where given with a range instead of a single figure, the figures are to be regarded as inclusive. For details and methods, see page 1236.

"*Negligible.*—The term, 'negligible,' where used in this Pharmacopœia, means a quantity not exceeding 0.0005 Gm.

"*Constant Weight.*—The term 'dried to constant weight,' where used in this Pharmacopœia, means that two consecutive weighings do not differ by more than 0.1 per cent, the second weighing following an additional hour of drying.

"*Quantities for Chemical Tests.*—In stating the quantities to be used for some assays and for quantitative tests for impurities a convenient amount is taken. The word 'about' is used to indicate that this need not be the exact quantity specified, but that it should be approximately that amount. This is then accurately weighed, and the result of the test or assay is to be based upon the exact weight. In those cases where the substances are corrosive, volatile, efflorescent, or hygroscopic, this plan will be found especially useful.

"Such phrases as '(1 in 10),' '(1 in 20),' etc., are understood to mean that 1 part by volume of a liquid is to be diluted with, or 1 part by weight of a solid dissolved in, 10 or 20 parts by volume of the solvent.

"'*Absence of' and 'Limit of'*.—The terms 'absence of' and 'limit of' following the tests indicating impurities are rarely used in this Pharmacopœia. Such words as (*chloride*), (*sulphate*) (*free alkali*), etc., in italics and parenthesis, which follow tests, are merely intended to give information as to the object of the test, the test itself indicating whether the substance is present in an amount which would be objectionable for medicinal use.

"*Temperatures.*—Statements of temperature are given in this Pharmacopœia in degrees of the centigrade thermometer, the equivalent Fahrenheit temperature being given in the Table of Thermometric Equivalents. The standard temperature for solubilities specific gravities, polarimetric determinations, and for the preparation of volumetric solutions is 25° C. For alcohol the former standard temperature of 60° F. (15.56° C.) has been retained, since the laws and regulations of the Internal Revenue Department of the United States, relating to alcohol and alcoholic liquids, are still based on this temperature.

"For refractive indices, viscosity, and for certain saccharimeters temperatures other than 25° C. have been directed as the special conditions require.

"When the Pharmacopœia directs the use of a water bath, it is understood that the water shall be boiling unless otherwise specified.

"*Specific Gravity.*—Except where otherwise stated, the specific gravity basis of this Pharmacopœia is $\frac{25° \text{ C.}}{25° \text{ C.}}$ (apparent), *i. e.*, the ratio of the apparent weight of a substance in air at 25° C. to that of an equal volume of distilled water at the same temperature.

"*Biological Assay Standards.*—In order to facilitate the adoption of the biological assay standards of the Pharmacopœia, and to provide a greater degree of uniformity in their application, the Bureau of Chemistry of the U. S. Department of Agriculture at Washington, D. C., has indicated its willingness to supply standard substances conforming to the pharmacopœial requirements.

"*Alcoholic Content in Preparations.*—In compliance with the instruction of the Pharmacopœial Convention there is given in the text accompanying each preparation containing alcohol, a range of alcohol content based upon numerous determinations and a compilation of data secured from pharmaceutical chemists and manufacturers. All statements of alcohol content under preparations are given in percentages of absolute alcohol. There is considerable variation in the amount of alcohol present in different lots of the same fluidextract due, to the varying proportions of moisture and extractive in the air-dried drug directed to be used, changing atmosphere conditions and the varying amounts of exposure; likewise if a process of 'percolation' or 'divided percolation' be adopted. Consequently, a much wider range of tolerance is necessary in some of the fluidextracts than would be permitted in a tincture or a spirit where the amount of drug and the exposure are much less.

"*Vegetable Drugs.*—The official definitions and standards for vegetable drugs, apply to all forms in which they may enter commerce, whether whole, cut, ground, powdered, or otherwise prepared for use, unless specifically exempted in the monograph or admitted under authority for manufacturing or for a special purpose. Vegetable drugs are to be as free as practicable from insects or other animal life, animal material or animal excreta. They are to be free from moldiness and show no discoloration, abnormal odor, sliminess, or deterioration due to any cause.

"For the preservation of vegetable or animal substances from the ravages of insects, it is directed in special cases that they be preserved in tightly-closed containers with a few drops of chloroform or carbon tetrachloride added. It is not intended that this precaution should be obligatory for drugs in bales or large original containers where it may be impracticable. The following drugs are particularly liable to the attack of insects: Aconite, althea, belladonna root, calumba, cantharides, capsicum, caraway, cardamom, ergot, ginger, glycyrrhiza, jalap, linseed, myristica, pumpkin seed, rhubarb, sarsaparilla, and strophanthus.

"In commerce it is not possible to obtain vegetable drugs in a state of absolute purity, and a limited amount of innocuous, extraneous, or foreign matter adhering to the drug or admixture with it is usually not detrimental. The presence or admixture of any poisonous or dangerous foreign substance, however, is not permissible. Foreign organic matter refers to any part of the plants or plants yielding the drug, except that part or those parts designated as constituting the drug, and to any other plant parts, vegetable tissues, or substances.

"In order that vegetable drugs be of uniform quality and as free as practicable from foreign substances, it is required that in each vegetable drug recognized in this Pharmacopœia the amount of foreign inorganic matter, estimated as acid-insoluble ash, be not more than 2 per cent of the weight of the drug unless otherwise specified in the monograph of the drug, and that amount of foreign organic matter be restricted to the allowable percentage specified in the monograph of the drug. Before vegetable drugs are ground or powdered, all lumps of dirt or other foreign inorganic matter which can be separated by mechanical means should be removed.

"*Weights and Measures.*—The metric system of weights and measures is the official system used in this Pharmacopœia. The units of the metric system are designated by abbreviations, as follows:

M. = meter
dm. = decimeter
cm. = centimeter
mm. = millimeter

L. = liter
dl. = deciliter
ml. = milliliter, or cubic centimeter, or cc.*

Kg. = kilogram
Gm. = gram
dg. = decigram
cg. = centigram
mg. = milligram

In measuring liquids, cylindrical graduates are preferred. Conical graduates, however, accurately graduated, are deemed suitable for the use of the pharmacist in compounding or dispensing medicines. The bottom of the meniscus is the point from which the reading is to be taken." *U. S.*

The Metric System of Weights and Measures, which is the only one recognized by either the United States or British Pharmacopœias in their formulæ, is based on the idea of a correlation between the units of length, capacity and weight, and multiples and subdivisions of these units according to the decimal system. The unit of length is the *meter*. The cube of the tenth part of a meter is taken as the unit of capacity and is called a *liter*. The one-thousandth part of a liter of distilled water at its maximum density is the unit of mass, and is denominated a *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes *Deka*, *Hecto*, *Kilo*, (spelt with capitals) taken from the Greek numerals and the subdivisions, following the same order, by *deci*, *centi*, *milli*, (spelt with small letters) from the Latin numerals.

---

*The cubic centimeter (cc.) used in this Pharmacopœia is intended to correspond to the one-thousandth part of a liter.

The following table shows the relative value of the linear measures; the equivalents of the Metric and Apothecaries weights and capacity measures are given in tables in Part III.

millimeter (mm.) = 0.001 meter = 0.039 inch
centimeter (cm.) = 0.01 meter = 0.394 inch
decimeter (dm.) = 0.1 meter = 3.937 inch
Meter (M.) = 39.37 inch
Dekameter (Dm.) = 10. meters = 10.94 yards
Hectometer (Hm.) = 100. meters = 109.36 yards
Kilometer (Km.) = 1000. meters = 0.621 mile

For equivalents of various multiples of the above measures see table of *Equivalents of Linear Measures*, Part III.

"*Apothecaries Weights and Measures.*—Physicians in prescribing, and pharmacists in dispensing medicines commonly employ the apothecaries weights and measures which were in use in England prior to 1825, the weights being orginally derived from the old English Troy weight, the fluid measures from the old wine gallon. The units of this system are designated in prescribing by signs or abbreviations as follows:

℥ = apothecaries ounce = 8 drachms = 480 grains
ʒ = drachm = 3 scruples = 60 grains
℈ = scruple = 20 grains
gr. = grain
O = pint = 16 fluidounces
f℥ = fluidounce = 8 fluidrachms = 480 minims
fʒ = fluidrachm = 60 minims
♏ = minim

"In writing prescriptions in the apothecaries system, Roman, not Arabic, numerals are employed, and these are always placed after the symbol or abbreviation, thus: f℥ii; gr.xv. In the case of metric abbreviations, the numerals precede the abbreviation, and are always written in Arabic characters, thus: 5 Gm.: 2 cc. Care is taken to distinguish the abbreviation for gram (Gm.) from that for grain (gr.) by writing the former with a capital, the latter with a small letter." U. S.

(For tables showing the relative value of the units of the various weights and measures employed in the United States and in Great Britain, also of the relations between the Apothecaries and metric systems see Part III.)

"*Approximate Measures.*—Physicians very commonly prescribe liquid medicines in teaspoonful, dessertspoonful, or tablespoonful doses. Inasmuch as spoons vary greatly in capacity, it is desirable that the more scientific practice should be always adopted, of prescribing doses in cubic centimeters, fluidrachms, or minims, to be measured with a suitable medicine measure. The following are the values conventionally attached to the several approximate measures above mentioned:

Metric System

A teaspoonful = 4 cc.
A dessertspoonful = 8 cc.
A tablespoonful = 15 cc.

Apothecaries System

A teaspoonful = 1 fluidrachm
A dessertspoonful = 2 fluidrachms
A tablespoonful = 4 fluidrachms or ½ fluidounce". U. S.

THE FOOD AND DRUGS ACT.

In force and effect from and after January 1, 1907.

AN ACT For preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be unlawful for any person to manufacture within any Territory of the District of Columbia any article of food or drug which is adulterated or misbranded, within the meaning of this Act; and any person who shall violate any of the provisions of this section shall be guilty of a misdemeanor, and for each offense shall, upon conviction thereof, be fined not to exceed five hundred dollars or shall be sentenced to one year's imprisonment, or both such fine and imprisonment, in the discretion of the court, and for each subsequent offense and conviction thereof shall be fined not less than one thousand dollars or sentenced to one year's imprisonment, or both such fine and imprisonment in the discretion of the court.

Sec. 2. That the introduction into any State or Territory or the District of Columbia from any other State or Territory or the District of Columbia, or from any foreign country or shipment to any foreign country of any article of food or drugs which is adulterated or misbranded, within the meaning of this Act, is hereby prohibited; and any person who shall ship or deliver for shipment from any State or Territory or the District of Columbia to any other State or Territory or the District of Columbia, or to a foreign country, or who shall receive in any State or Territory, or the District of Columbia from any other State or Territory or the District of Columbia, or foreign country, and having so received, shall deliver, in original unbroken packages, for pay or otherwise, or offer to deliver to any other person, any such article so adulterated or misbranded within the meaning of this Act, or any person who shall sell or offer for sale in the District of Columbia or the Territories of the United States any such adulterated or misbranded foods or drugs, or export or offer to export the same to any foreign country, shall be guilty of a misdemeanor, and for such offense be fined not exceeding two hundred dollars for the first offense, and upon conviction for each subsequent offense not exceeding three hundred dollars or be imprisoned not exceeding one year, or both, in the discretion of the court: *Provided,* That no article shall be deemed misbranded or adulterated within the provisions of this Act when intended for export to any foreign country and prepared or packed according to the specifications or directions of the foreign purchaser when no substance is used in the preparation or packing thereof in conflict with the laws of the foreign country to which said article is intended to be shipped; but if said article shall be in fact sold or offered for sale for domestic use or consumption, then this proviso shall not exempt said article from the operation of any of the other provisions of this Act.

Sec. 3. That the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor shall make uniform rules and regulations for carrying out the provisions of this Act, including the collection and examination of specimens of foods and drugs manufactured or offered for sale in the District of Columbia, or in any Territory of the United States, or which shall be offered for sale in unbroken packages in

First: In the case of mixtures or compounds which may be now or from time to time hereafter known as articles of food, under their own distinctive names, and not an imitation of or offered for sale under the distinctive name of another article, if the name be accompanied on the same label or brand with a statement of the place where said article has been manufactured or produced.

Second. In the case of articles labeled, branded, or tagged so as to plainly indicate that they are compounds, imitations, or blends, and the word "compound," "imitation" or "blend," as the case may be, is plainly stated on the package in which it is offered for sale: *Provided*, That the term blend as used herein shall be construed to mean a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only: *And provided further*, That nothing in this Act shall be construed as requiring or compelling proprietors or manufacturers of proprietary foods which contain no unwholesome added ingredient to disclose their trade formulas, except in so far as the provisions of this Act may require to secure freedom from adulteration or misbranding.

Sec. 9. That no dealer shall be prosecuted under the provisions of this Act, when he can establish a guaranty signed by the wholesaler, jobber, manufacturer, or other party residing in the United States, from whom he purchases such articles, to the effect that the same is not adulterated or misbranded within the meaning of this Act, designating it. Said guaranty, to afford protection, shall contain the name and address of the party or parties making the sale of such articles to such dealer, and in such case said party or parties shall be amenable to the prosecutions, fines, and other penalties which would attach, in due course, to the dealer under the provisions of this Act.

Sec. 10. That any article of food, drug, or liquor that is adulterated or misbranded within the meaning of this Act, and is being transported from one State, Territory, District, or insular possession to another for sale, or, having been transported, remains unloaded, unsold, or in original unbroken packages, or if it be sold or offered for sale in the District of Columbia or the Territories, or insular possessions of the United States, or if it be imported from a foreign country for sale, or if it is intended for export to a foreign country, shall be liable to be proceeded against in any district court of the United States within the district where the same is found, and seized for confiscation by a process of libel for condemnation. And if such article is condemned as being adulterated or misbranded or of a poisonous or deleterious character, within the meaning of this Act, the same shall be disposed of by destruction or sale, as the said court may direct, and the proceeds thereof, if sold, less the legal costs and charges, shall be paid into the Treasury of the United States, but such goods shall not be sold in any jurisdiction contrary to the provisions of this Act or the laws of that jurisdiction: *Provided, however*, That upon the payment of the costs of such libel proceedings and the execution and delivery of a good and sufficient bond to the effect that such articles shall not be sold or otherwise disposed of contrary to the provisions of this Act, or the laws of any State, Territory, District, or insular possession, the court may by order direct that such articles be delivered to the owner thereof. The proceedings of such libel cases shall conform, as near as may be, to the preceedings in admiralty, except that either party may demand trial by jury of any issue of fact joined in any such case, and all such proceedings shall be at the suit of and in the name of the United States.

Sec. 11. The Secretary of the Treasury shall deliver to the Secretary of Agriculture, upon his request from time to time, samples of foods and drugs which are being imported into the United States or offered for import, giving notice thereof to the owner or consignee who may appear before the Secretary of Agriculture, and have the right to introduce testimony, and if it appear from the examination of such samples that any article of food or drug offered to be imported into the United States is adulterated or misbranded within the meaning of this Act, or is otherwise dangerous to the health of the people of the United States, or is of a kind forbidden entry into, or forbidden to be sold, or restricted in sale in the country in which it is made or from which it is exported, or is otherwise falsely labeled in any respect, the said article shall be refused admission, and the Secretary of the Treasury shall refuse delivery to the consignee and shall cause the destruction of any goods refused delivery which shall not be exported by the consignee within three months from the date of notice of such refusal under such regulations as the Secretary of the Treasury may prescribe: *Provided*, That the Secretary of the Treasury may deliver to the consignee such goods pending examination and decision in the matter on execution of a penal bond for the amount of the full invoice value of such goods, together with the duty thereon, and on refusal to return such goods for any cause to the custody of the Secretary of the Treasury when demanded, for the purpose of excluding them from the country, or for any other purpose, said consignee shall forfeit the full amount of the bond: *And provided further*, That all charges for storage, cartage, and labor on goods which are refused admission or delivery shall be paid by the owner or consignee and in default of such payment shall constitute a lien against any future importation made by such owner or consignee.

Sec. 12. That the term "Territory" as used in this act shall include the insular possessions of the United States. The word "person" as used in this Act shall be construed to import both plural and the singular, as the case demands, and shall include corporations, companies, societies and associations. When construing and enforcing the provisions of this Act, the act, omission, or failure of any officer, agent, or other person acting for or employed by any corporation, company, society, or association, within the scope of his employment or office, shall in every case be also deemed to be the act, omission, or failure of such corporation, company, society, or association as well as that of the person.

Sec. 13. That this Act shall be in force and effect from and after the first day of January, nineteen hundred and seven.

Approved, June 30, 1906.

REGULATIONS FOR THE ENFORCEMENT OF THE FOOD AND DRUGS ACT.

The regulations promulgated by the Department of Agriculture from time to time for the enforcement of this act have become so numerous and voluminous that it is impracticable to give even a summary of them. In these regulations are included definitions of certain terms used in the trade, standards for quality of foods, and of some drug products, as well as rules concerning the form of label etc. The food and drugs code has become so complex that the Bureau of Chemistry has recently (May 1925) issued a summary of the regulations for the guidance of manufacturers of and dealers in drugs. This circular follows.

INFORMATION ON DRUGS.

1. Scope of the Food and Drugs Act.

The Federal food and drugs act applies to all drugs which enter interstate or foreign commerce, or are made, sold, or offered for sale in any Territory of the United States (including the insular possessions) or the District of Columbia.

2. Definition of "Drug."

The term "drug," as defined by section 6 of the act, includes "all medicines and preparations recognized in the United States Pharmacopœia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals."

3. Permit or License.

Nothing in the act provides for the issuance of permits or licenses or authorizes the approval of preparations or labels. Therefore, it is unnecessary to submit samples or formulas of medicinal preparations to the Bureau of Chemistry for examination or approval.

4. Ingredients Required to be Declared.

The act does not specify the substances that may or may not be used as ingredients, but it does require that the quantity or proportion of the substances referred to in section 8, second paragraph, under "In case of drugs" (Circular 21, page 25), present in drug products shall be plainly stated on the label of the container, and on the carton or wrapper (Regulation 24, Circular 21, page 12). The method of declaring the quantity or proportion of such substances or their derivatives mentioned in the paragraph cited above is set forth in Regulation 25. A declaration of the ingredients or formula is not ordinarily required, but if made it should be complete and correct (Regulation 14, (f), (g), and (h), Circular 21, page 9).

5. Declaration of Specially Denatured Alcohol.

The Bureau of Internal Revenue has authorized the use of specially denatured alcohol in the manufacture of certain drugs. Some of the denaturants permitted are derivatives of alcohol. For the present the requirements of the Federal food and drugs act relating to the declaration of alcohol and its derivatives will be considered satisfied by either:

(*a*) Declaration of the percentages of alcohol and of each of its derivatives present as a denaturant in the finished product, or

(*b*) Declaration of the percentage of specially denatured alcohol in the finished product.

If (*b*) is chosen, the number of the formula of the denatured alcohol used should be stated. For example, if a product contains 50 per cent. of specially denatured alcohol, formula 23-B, the declaration should be "Contains 50% Specially Denatured Alcohol, Formula 23-B."

6. Labeling.

(*a*) In section 8 the general paragraph and the three subparagraphs under the heading "In case of drugs" deal with misbrandings. The word "label" has been interpreted by the courts to cover any printed matter that accompanies the package, such as shipping container, wrapper box, carton, bottle label, booklet, or circular (Regulation 14, Circular 21, page 8).

(*b*) In a labeling the manufacturer should avoid any suggestion, hint, or insinuation, direct or indirect, by statement, design, or device, that may tend to convey a misleading impression in any particular, and also any unwarranted representations that are indefinite or of general sweeping character. It is the duty of the manufacturer to carefully consider whether the statements he proposed to put on his labeling are strictly in harmony with the facts.

(*c*) Care must be taken that on the labeling appears no misrepresentation, expressed or implied, as to the therapeutic effect of the product. In making statements of therapeutic efficacy on a label a manufacturer assumes the position of one having a special knowledge of disease and its treatment, and the United States Supreme Court has ruled that he can be held accountable accordingly. Under the law he is responsible for his statements or representations, and no one can relieve him of this responsibility. Personal belief, testimonials in general, dispensatories, scattered isolated excerpts from medical publications, obsolete medical books and discarded medical practices are not adequate authorities for therapeutic claims; the consensus of present-day medical opinion is the standard which should guide manufacturers in labeling. A preparation cannot properly bear promises of benefit unless as a matter of fact it can be reasonably depended upon to produce the results claimed for it.

7. Names of Diseases.

A judicial decision states: "Language used in the label is to be given the meaning ordinarily conveyed by it to those to whom it was addressed." The printing of names of diseases or disorders on the labeling of a medicine for public sale conveys to the purchaser the impression that the product in itself is a competent treatment for the diseases mentioned. One who is seeking something that will rid him of his trouble is more concerned with the names of the affections for which the product is recommended than with the style of language employed. Regardless of whether the product is recommended as a "cure," "remedy," "relief," "useful in the treatment of," "indicated for," or simply "for," certain affections, the question is whether or not the product in itself, by reason of the contained ingredients, constitutes a treatment for the disorders named. The names of diseases in a labeling, therefore, should be limited to those for which the article, in view of the recognized medicinal action of its ingredients, considered singly or in combination, is a treatment. Names of organs or portions of the body should not appear upon a labeling unless the product can properly be considered a treatment for any and all disorders to which such organs or parts may be subject.

8. Testimonials.

No statement relative to the therapeutic effect of a preparation should be made in the form of a testimonial for which the manufacturer is not willing to bear the full responsibility. Representations of curative or beneficial effect conveyed by testimonials are subject to the same requirements as other therapeutic claims. When a manufacturer publishes a testimonial to the effect that his medicine has produced certain results, he conveys to others the promise of a similar benefit, and he must assume the responsibility for all therapeutic claims made in this manner to the same extent that he does for promises of benefit made in his own words. That the testimonial may be bona fide and accurately quoted does not relieve him of this responsibility.

9. Collateral Advertising.

Collateral advertising in newspapers and elsewhere and claims made by agents determine the meaning of any indefinite or obscure statements or representations in the labeling. The wording of collateral advertising should in no instance exceed, in the impressions produced, the terms of the labeling. No interpretation of, or reference to, the terms of the label should be used to create an impression in the mind of the purchaser that the preparation is a remedy, treatment, or preventive for diseases for which, in fact, it is not.

10. Approval of Labeling.

Under the law there is no authority to approve or suggest labelings, formulas, trade names, or advertising literature. Numerous requests are referred to this department for the approval of labels. The act does not authorize the department to give such approval, and any printed matter upon the label implying that this department has approved it will be without warrant.

11. Important Quotation from Opinion of U. S. Supreme Court on Food and Drugs Act.

"The statute is plain and direct. Its comprehensive terms condemn every statement, design, and device which may mislead or deceive. Deception may result from the use of statements not technically false or which may be literally true. The aim of the statute is to prevent that resulting from indirection and ambiguity, as well as from statements which are false. It is not difficult to choose statements, designs and devices which will not deceive. Those which are ambiguous and liable to mislead should be read favorably to the accomplishment of the purpose of the act." (From Opinion of the Supreme Court of the United States in United States vs. 95 Barrells, Et Al., No. 559, October Term, 1923.)

12. Guaranty and Serial Number.

On May 5, 1914, all guaranties on file with the Secretary of Agriculture were stricken from the files and all serial numbers cancelled. It is, therefore, no longer permissible to use either the serial number or guaranty legend on the label or package of food or drug products that come within the jurisdiction of the Federal food and drugs act. In this connection your attention is called to Regulation 6, page 5, Circular 21, which explains the permissible use of a guaranty.

13. Requests for Information Regarding Specific Preparations.

The bureau is authorized to give out information concerning the quality and composition of preparations upon the market only in the form of notices of judgment, published after court action, as authorized by section 4, page 23, Circular 21. Requests for information concerning specific products can be complied with only in those instances where notices of judgment are available.

14. Requests for Analysis.

The examination of samples of medicinal preparations is limited to those of an official character, collected by authorized agents of the department. Requests for analysis can not be complied with, since no authority or appropriation exists for such work.

15. Statement of Weight, Measure, or Count.

The act does not require that the label of drugs shall bear a statement of the weight, measure, or numerical count of the contents of the package, but any statement of this nature should be correct and complete.

16. Toilet Preparations.

The act deals with foods and drugs, the term "drug" being defined in section 6, page 24, Circular 21. A toilet preparation that is not intended or represented, directly or indirectly, to be useful for the cure, mitigation, or prevention of disease is not subject to the law, but the manufacturer should exercise care that it does not contain any ingredient that might be injurious to health.

17. Narcotic Act and Prohibition Act.

Narcotics and alcohol are subject to the provisions of the Harrison narcotic act and the prohibition act, as well as to the provisions of the food and drugs act. Information regarding these two laws may be obtained from the Bureau of Internal Revenue, Washington, D. C.

18. Postal Laws.

The postal laws and regulations contain provisions as to drug products coming within their scope. Information on this subject can be obtained by addressing the Postmaster General, Washington, D. C.

19. Patents and Trade-marks.

The Department of Agriculture can give no advice on patents or trade-marks. Information on this subject may be obtained by addressing the Commissioner of Patents, Washington, D. C. As far as the Federal food and drugs act is concerned, no patent, trade-mark or copyright is necessary for the manufacture or sale of drug products.

20. Copyright.

Information regarding copyright privileges may be obtained by addressing the Copyright Division, Library of Congress, Washington, D. C.

21. Patents, Trade-marks and Copyrights Confer No Exemption.

The issuance of a trade-mark, copyright, or patent for a preparation does not exempt it from the provisions of the Federal food and drugs act.

22. State Laws.

State laws may contain additional requirements for the manufacture or sale of medicinal preparations.

HARRISON NARCOTIC ACT.

Production, Importation, Manufacture, Compounding, Sale, Dispensing, or Giving Away of Opium or Coca Leaves, their Salts, Derivatives, or Preparations.

THE LAW

By an act of Congress approved December 17, 1914, it is provided:

Persons who are required to register.

That on and after the first day of March, nineteen hundred and fifteen, every person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, shall register with the collector of internal revenue of the district his name or style, place of business, and place or places where such business is to be carried on: *Provided*, That the office, or if none, then the residence of any person shall be considered for the purpose of this Act to be his place of business. At the time of such registry and on or before the first day of July, annually thereafter, every person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away any of the aforesaid drugs shall pay to the said collector a special tax at the rate of $1 per annum: *Provided*, That no employee of any person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away any of the aforesaid drugs, acting within the scope of his employment, shall be required to register or to pay the special tax provided by this section: *Provided further*, That the person who employs him shall have registered and paid the special tax as required by this section: *Provided further*, That officers of the United States Government who are lawfully engaged in making purchases of the above-named drugs for the various departments of the Army and Navy, the Public Health Service, and for Government hospitals and prisons, and officers of any State government, or of any county or municipality therein, who are lawfully engaged in making purchases of the above-named drugs for State, county, or municipal hospitals or prisons, and officials of and Territory or insular possession or the District of Columbia or of the United States who are lawfully engaged in making purchases of the above-named drugs for hospitals or prisons therein shall not be required to register and pay the special tax as herein required.

Special tax to be paid.

Exemption — Drugs purchased for U. S., etc.

Failure to register and to pay special tax.

It shall be unlawful for any person required to register under the terms of this Act to produce, import, manufacture, compound, deal in, dispense, sell, distribute, or give away any of the aforesaid drugs without having registered and paid the special tax provided for in this section.

Word "person" to include partnership, etc.

That the word "person" as used in this Act shall be construed to mean and include a partnership, association, company, or corporation, as well as a natural person; and all provisions of existing law relating to special taxes so far as applicable, including the provisions of section thirty-two hundred and forty of the Revised Statutes of the United States are hereby extended to the special tax herein imposed.

Regulations to be prescribed.

That the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall make all needful rules and regulations for carrying the provisions of this Act into effect.

Purchase orders required.

Section 2. That it shall be unlawful for any person to sell, barter, exchange, or give away any of the aforesaid drugs except in pursuance of a written order of the person to whom such article is sold, bartered, exchanged, or given, on a form to be issued in blank for that purpose by the Commissioner of Internal Revenue. Every person who shall accept any such order, and in pursuance thereof shall sell, barter, exchange, or give away any of the aforesaid drugs, shall preserve such order for a period of two years in such a way as to be readily accessible to inspection by any officer agent, or employee of the Treasury Department duly authorized for that purpose. and the State, Territorial District, municipal, and insular officials named in section five of this Act. Every person who shall give an order as herein provided to any other person for any of the aforesaid drugs shall, at or before the time of giving such order, make or cause to be made a duplicate thereof on a form to be issued in blank for that purpose by the Commissioner of Internal Revenue, and in case of the acceptance of such order, shall preserve such duplicate for said period of two years in such a way as to be readily accessible to inspection

Orders to be preserved for 2 years. Inspection of same by officers, agents, etc.

Duplicate orders to be retained by purchaser.

by the officers, agents, employees, and officials hereinbefore mentioned. Nothing contained in this section shall apply—

Exemptions—Drugs dispensed to patient, in certain cases.

(*a*) To the dispensing or distribution of any of the aforesaid drugs to a patient by a physician, dentist, or veterinary surgeon registered under this Act in the course of his professional practice only: *Provided:* That such physician, dentist, or veterinary surgeon shall keep a record of all such drugs dispensed or distributed, showing the amount dispensed or distributed, the date, and the name and address of the patient to whom such drugs are dispensed or distributed, except such as may be dispensed or distributed to a patient upon whom such physician, dentist or veterinary surgeon shall personally attend; and such record shall be kept for a period of two years from the date of dispensing or distributing such drugs, subject to inspection, as provided in this Act.

Prescriptions—how to be issued and signed.

Prescriptions to be preserved for 2 years.

(*b*) To the sale, dispensing, or distribution of any of the aforesaid drugs by a dealer to a consumer under and in pursuance of a written prescription issued by a physician, dentist, or veterinary surgeon registered under this Act: *Provided, however,* That such prescription shall be dated as of the day on which signed and shall be signed by the physician, dentist, or veterinary surgeon who shall have issued the same: *And Provided, further,* That such dealer shall preserve such prescription for a period of two years from the day on which such prescription is filled in such a way as to be readily accessible to inspection by the officers, agents, employees, and officials hereinbefore mentioned.

Exemption—drugs shipped to a foreign country.

(*c*) To the sale, exportation, shipment or delivery of any of the aforesaid drugs by any person within the United States or any Territory or the District of Columbia or any of the insular possessions of the United States to any person in any foreign country, regulating their entry in accordance with such regulations for importation thereof into such foreign country as are prescribed by said country, such regulations to be promulgated from time to time by the Secretary of State of the United States.

Sales, etc., to Department of Army, Navy, etc.

(*d*) To the sale, barter, exchange, or giving away of any of the aforesaid drugs to any officer of the United States Government or of any State, territorial, district, county, or municipal or insular government lawfully engaged in making purchases thereof for the various departments of the Army and Navy, the Public Health Service, and for Government, State, territorial district, county, or municipal or insular hospitals or prisons.

Blank forms to be provided.

Sale of same.

Collector to keep account of sales.

Blanks to be sold only to persons who have registered.

Unlawful use of forms.

The Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall cause suitable forms to be prepared for the purposes above mentioned, and shall cause the same to be distributed to collectors of internal revenue for sale by them to those persons who shall have registered and paid the special tax as required by section one of this Act in their districts, respectively; and no collector shall sell any of such forms to any persons other than a person who has registered and paid the special tax as required by section one of this Act in his district. The price at which such forms shall be sold by said collectors shall be fixed by the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, but shall not exceed the sum of $1 per hundred. Every collector shall keep an account of the number of such forms sold by him, the names of the purchasers, and the number of such forms sold to each of such purchasers. Whenever any collector shall sell any of such forms, he shall cause the name of the purchaser thereof to be plainly written or stamped thereon before delivering the same, and no person other than such purchaser shall use any of said forms bearing the name of such purchaser for the purpose of procuring any of the aforesaid drugs, or furnish any of the forms bearing the name of such purchaser to any person with intent thereby to procure the shipment or delivery of any of the aforesaid drugs. It shall be unlawful for any person to obtain by means of said order forms any of the aforesaid drugs for any purpose other than the use, sale, or distribution thereof by him in the conduct of a lawful business in said drugs or in the legitimate practice of his profession.

Porto Rico and Philippine Islands.

Canal Zone.

The provisions of this Act shall apply to the United States, the District of Columbia, the Territory of Alaska, the Territory of Hawaii, the insular possessions of the United States, and the Canal Zone. In Porto Rico and the Philippine Islands the administration of this Act, the collection of the said special tax, and the issuance of the order forms specified in section two shall be performed by the appropriate internal-revenue officers of those governments, and all revenues collected hereunder in Porto Rico and the Philippine Islands shall accrue intact to the general governments thereof, respectively. The courts of first instance in the Philippine Islands shall possess and exercise jurisdiction in all cases arising under this Act in said islands. The President is authorized and directed to issue such Executive orders as will carry into effect in the Canal Zone the intent and purpose of this Act by providing for the registration and the imposition of a special tax upon all persons in the Canal Zone who produce, import, compound, deal in, dispense, sell, distribute, or give away opium or coca leaves, their salts, derivatives, or preparations.

Collector may require sworn statement as to drugs received.

Section 3. That any person who shall be registered in any internal-revenue district under the provisions of section one of this Act, shall whenever required so to do by the collector of the district, tender to the said collector a true and correct statement or return, verified by affidavit, setting forth the quantity of the aforesaid drugs received by him in said internal-revenue district during such period immediately preceding the demand of the collector, not exceeding three months, as the said collector may fix and determine; the names of the persons from whom the said drugs were received; the quantity in each instance received from each of such persons, and the date when received

Shipment of drugs unlawful, except—

Common carriers and employees exempt.

Section 4. That it shall be unlawful for any person who shall not have registered and paid the special tax as required by section one of this Act to send, ship, carry or deliver any of the aforesaid drugs from any State or Territory or the District of Columbia, or any insular possession of the United States, to any person in any other State or Territory or the District of Columbia or any insular possession of the United States: *Provided*, That nothing contained in this section shall apply to common carriers engaged in transporting the aforesaid drugs, or to any employee acting within the scope of his employment, of any person who shall have registered and paid the special tax as required by section one of this Act, or to any person who shall deliver any such drug which has been prescribed or dispensed by a physician, dentist, or veterinarian required to register under the terms of this Act, who has been employed to prescribe for the particular patient receiving such drug, or to any United States, State, county, municipal, District, Territorial, or insular officer or official acting within the scope of his official duties.

Orderforms, prescriptions, and statements filed to be open to inspection of officers.

Certified copies of statements and returns to be furnished by collectors.

Fees.

Penalty for disclosing information, except—

Certified list of names may be furnished.

Section 5. That the duplicate-order forms and the prescriptions required to be preserved under the provisions of section two of this Act, and the statements or returns filed in the office of the collector of the district, under the provisions of section three of this Act, shall be open to inspection by officers, agents, and employees of the Treasury Department duly authorized for that purpose; and such officials of any State or Territory, or of any organized municipality therein, or of the District of Columbia, or any insular possession of the United States, as shall be charged with the enforcement of any law or municipal ordinance regulating the sale prescribing, dispensing, dealing in, or distribution of the aforesaid drugs. Each collector of internal revenue is hereby authorized to furnish, upon written request, certified copies of any of the said statements or returns filed in his office to any of such officials of any State or Territory or organized municipality therein, or the District of Columbia, or any insular possession of the United States, as shall be entitled to inspect the said statements or returns filed in the office of the said collector, upon the payment of a fee of $1 for each one hundred words or fraction thereof in the copy or copies so requested. Any person who shall disclose the information contained in the said statements or returns or in the said duplicate-order forms, except as herein expressly provided, and except for the purpose of enforcing the provisions of this Act, or for the purpose of enforcing any law of any state or Territory of the District of Columbia, or any insular possession of the United States, or ordinance of any organized municipality therein, regulating the sale, prescribing, dispensing, dealing in, or distribution of the aforesaid drugs, shall, on conviction, be fined or imprisoned as provided by section nine of this Act. And collectors of internal revenue are hereby authorized to furnish upon written request, to any person, a certified copy of the names of any or all persons who may be listed in their respective collection districts as special tax payers under the provisions of this Act, upon payment of a fee of $1 for each one hundred names or fraction thereof in the copy so requested.

Act not to apply to certain preparations, etc.

Conditions imposed.

Decocainized coca leaves.

Section 6. That the provisions of this Act shall not be construed to apply to the sale, distribution, giving away, dispensing, or possession of preparations and remedies which do not contain more than two grains of opium, or more than one-fourth of a grain of morphine, or more than one-eighth of a grain of heroin, or more than one grain of codeine, or any salt or derivative of any of them in one fluid ounce, or, if a solid or semisolid preparation, in one avoirdupois ounce, or to liniments, ointments, or other preparations which are prepared for external use only, except liniments, ointments, and other preparations which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or any synthetic substitute for them: *Provided*, That such remedies and preparations are sold, distributed, given away, dispensed, or possessed as medicines and not for the purpose of evading the intentions and provisions of this Act. The provisions of this Act shall not apply to decocainized coca leaves or preparations made therefrom, or to other preparations of coca leaves which do not contain cocaine.

Certain revenue laws made applicable.

Section 7. That all laws relating to the assessment, collection, remission, and refund of internal-revenue taxes including section thirty-two hundred and twenty-nine of the Revised Statutes of the United States, so far as applicable to and not inconsistent with the provisions of this Act, are hereby extended and made applicable to the special taxes imposed by this Act.

Possession of drugs prohibited, except—

Certain persons exempt.

Burden of proof on defendant.

SECTION 8. That it shall be unlawful for any person not registered under the provisions of this Act, and who has not paid the special tax provided for by this Act, to have in his possession or under his control any of the aforesaid drugs; and such possession or control shall be presumptive evidence of a violation of this section, and also of a violation of the provisions of section one of this Act: *Provided,* That this section shall not apply to any employee of a registered person, or to a nurse under the supervision of a physician, dentist, or veterinary surgeon registered under this Act, having such possession or control by virtue of his employment or occupation and not on his own account; or to the possession of any of the aforesaid drugs which has or have been prescribed in good faith by a physician, dentist, or veterinary surgeon registered under this Act; or to any United States, State, county, municipal, District, Territorial, or insular officer or official who has possession of any said drugs, by reason of his official duties, or to a warehouseman holding possession for a person registered and who has paid the taxes under this Act; or to common carriers engaged in transporting such drugs: *Provided further*, That it shall not be necessary to negative any of the aforesaid exemptions in any complaint, information, indictment, or other writ or proceeding laid or brought under this Act; and the burden of proof of any such exemption shall be upon the defendant.

Penalties.

SECTION 9. That any person who violates or fails or comply with any of the requirements of this Act, shall, on conviction, be fined not more than $2,000 or be imprisoned not more than five years, or both, in the discretion of the court.

Appointment of agents, deputy collectors, etc.

SECTION 10. That the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, is authorized to appoint such agents, deputy collectors, inspectors, chemists, assistant chemists, clerks or messengers in the field and in the Bureau of Internal Revenue in the District of Columbia as may be necessary to enforce the provisions of this Act.

Appropriation.

SECTION 11. That the sum of $150,000, or so much thereof as may be necessary, be, and hereby is, appropriated, out of any moneys in the Treasury not otherwise appropriated, for the purpose of carrying into effect the provisions of this Act.

Act not to be construed as impairing or repealing certain acts.

SECTION 12. That nothing contained in this Act shall be construed to impair alter, amend, or repeal any of the provisions of the Act of Congress approved June thirtieth, nineteen hundred and six, entitled "An Act for preventing the manufacture, sale, or transportation of adulterated or misbranded, or poisonous, or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes," and any amendment thereof, or of the Act approved February ninth, nineteen hundred and nine, entitled "An Act to prohibit the importation and use of opium for other than medicinal purposes," and any amendment thereof.

THE DISPENSATORY OF THE UNITED STATES

PART I

DRUGS RECOGNIZED BY THE UNITED STATES PHARMACOPŒIA, THE PHARMACOPŒIA OF GREAT BRITAIN, OR THE NATIONAL FORMULARY.

ACACIA. U. S. (Br.)

ACACIA Acac. [Gum Arabic]

"Acacia is the dried gummy exudation from the stems and branches of *Acacia Senegal* Willdenow or of some other species of *Acacia* (Fam. *Leguminosæ*). Acacia yields not more than 1 per cent. of water-insoluble residue, and not more than 15 per cent. of moisture." *U. S.* "A gummy exudation from the stem and branches of Acacia Senegal, *Willd.*, and of other species of Acacia, *Willd.*" *Br.*

Acaciæ Gummi, *Br.;* Gummi Africanum; Gummi Mimosæ; Gum Acacia; Galam Gum; Arabicum Gummi, *Fr. Cod,* Gomme Arabique Gomme du Sénégal, *Fr.;* Gummi Arabicum; *P. G.;* Arabisches Gummi, *G.;* Gomma Arabica, Gomma del Cordofan, *It.;* Goma Arabiga, *Sp.;* Samagh Arabee, *Arab.*

The name *Acacia* was employed by the ancient Greeks to designate the gum tree of Egypt, and has been appropriately applied to the genus in which that plant is included.

The most important of the gum-yielding Acacias is the official *A. Senegal* Willd. This is a small tree rarely exceeding a height of 6 m., with a grayish bark, the inner layers of which are strongly fibrous, bipinnate leaves, dense spikes of small yellow flowers longer than the leaves, and broad pods containing 5 or 6 seeds. It forms large forests in Western Africa, north of the river Senegal, and is abundant in Eastern Africa, Khordofan, and Southern Nubia. It is known by the natives of Senegambia as *Verek* and of Khordofan as *Hashab.*

Nearly all species of Acacia growing in Africa yield a gum. The commercial *Somali gum,* which is usually of fair quality, is yielded by *A. glaucophylla* Steud. and *A. abyssinica* Hochst., shrubs growing in Abyssinia and the Somali country. The following species yield a gum having a brownish or reddish color, and hence are less valuable, viz., *A. arabica* Willd. (*Amrad gum*), *A. stenocarpa* Hochst., *A. Seyal* Del. and *A. Ehrenbergiana* Hayne. Inferior gums are also yielded by the following: *A. horrida* Willd., which furnishes the so-called *Cape gum* and is distinguished by being very brittle and yielding a less adhesive mucilage. *Talca* or *Sennarr gum* is derived from *A. Fistula* Schweinf. This gum has a greenish tinge and yields a ropy mucilage. *Amritsar gum* is obtained from *A. modesta* Wall. It occurs in large brown tears and like *A. arabica* is used in calico printing. *Mogadore gum,* derived from *A. gummifera* Willd., occurs in dark brown tears which are little fissured. *Australian gum* has usually a reddish color, said to be due to the presence of tannin, although some specimens are light in color and scarcely distinguishable from acacia. This gum is also spoken of as *Wattle gum* or *Australian gum,* and is derived from the *Golden Wattle* (*A. pycnantha* Benth.), a shrub growing in New South Wales, Victoria and Southern Australia.

The bark and unripe fruit of the acacia contain both tannic and gallic acids. The dried juice of the pod was used by the ancient Greeks; and an extract is still sold in the bazaars of India under the name of *Akakia.* This extract is heavy, hard, of an agreeable odor, varying in color from greenish to dark-reddish, or, when seen in bulk, blackish. It has a sweet, astringent taste, and yields a mucilaginous infusion. A similar preparation, *acacia nostras,* has been prepared in Europe by expression and inspissation from the unripe fruit of *Prunus spinosa,* or wild plum tree.

The gum of the acacias exudes spontaneously from the bark, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. The gum is said also to be found immediately under the bark, where it is sometimes collected in regular cavities. It is formed within the plant by metamorphosis of the cells of the inner bark. The tissues involved are chiefly those of the sieve and the cambium. While to some extent it is a natural change, yet it is usually looked upon as being in part a pathological production, as gummosus develops more largely upon the wounding of the trees. The attack of the Acacia plants by various parasites is held by some to account for the enormous production of gums in these plants. The investigations of Smith tend to show that all vegetable gums are of bacterial origin and that the differences in the several gums are due to the differences in the nature of the bacteria producing them. (*Proc. Linn. Soc. N. S. Wales,* 1904, p. 217.) For further discussion on the origin of acacia gum see Tschirch, *"Handbuch der Pharmakognosie,"* and Greenish, *"Materia Medica,"* 3rd ed.

The trees are not tapped for gum until they are about six years old. The annual yield varies very greatly, being from 188 to 2856 Gm. in young trees and from 379 to 6754 Gm. in large trees. The average annual yield of gum from young trees is about 900 Gm. and from old trees over 2 kilos. (Edie, 4th Report of the *Wellcome Tropical Research Laboratory.*)

It is stated by Jackson that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential, for in cooler climates, though the tree may flourish, it yields no gum. It is probable that some species of acacia yield finer gum than others, but it is also certain that the same tree will often yield some gum of the finest quality in regular tears or globular masses, and some irregular shaped, dark colored fragments of inferior value. Thus, from the same tree it will exude, frothy or thick, and clear or dark colored, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce. This sorting is usually done on its arrival in European ports and only the selected or picked gum corresponding to the U. S. P. description should be used.

Commercial History and Varieties.—There are two principal commercial varieties of gum arabic: 1. The Khordofan or Arabian Gum and 2. The Senegal or West African Gum, both of these being derived from *A. Senegal*. The former of these has the finer commercial qualities, being nearly white or faint yellowish-white and yielding a more or less transparent viscid mucilage.

KHORDOFAN OR ARABIAN GUM.—This is the finest variety of gum arabic obtainable. It was formerly the only kind designated as gum arabic and entered commerce almost exclusively through Egypt, being collected in Upper Egypt, Nubia, Khordofan, Darfur, and other regions of the Upper Nile, and carried to Alexandria, whence it passed directly into the world's commerce or entered the latter through Smyrna, Trieste, or some other Mediterranean entrepôt. At one time the more or less colored varieties were known as *gum gedda,* while the white and fine drug was known as *gum turic,* names derived from Jiddah and Tor, Red Sea ports, through which the varieties were supposed to be respectively exported. Three chief commercial varieties were formerly recognized. (*a*) *Hashabi* or *Khordofan gum,* the finest of these varieties, was collected in the country westward of the White Nile; formerly it constituted the bulk of the superior gum arabic of commerce. (*b*) *Sennari gum* was an inferior variety, yielding a mucilage which turned sour more quickly than that produced by Khordofan gum. It was collected in a country eastward of the White Nile, and in the region of the Blue Nile. (*c*) *Ghezzirah* or *Gezireh gum* is obtained from Ghezzirah and neighboring countries and sent to Trieste. It has much of the same appearance as the official Khordofan gum.

Formerly, Khordofan gum was collected in all parts of the Soudan and Upper Egypt, and forwarded on the backs of camels to Assouan, at the head of the Nile navigation, often being many months en route. The closure of the Soudan by the Mahdi caused Egyptian gum almost to disappear from commerce, but the reopening of the region by the British government has resulted in large quantities of the gum being brought by rail to Assouan, whence after being sorted into three varieties it is put in palm-leaf sacks and sent down the Nile. The finest Egyptian gum consists of large roundish or smaller more or less irregular fragments, transparent but usually rendered opaque upon the surface by innumerable minute fissures. The inferior gum varies from yellow to dark-reddish as the quality deteriorates, and often contains impurities. H. C. Wood found that the gum arabic comes into Assouan in sacks or mats which are simply piled in rectangular roofless spaces surrounded by walls about ten feet high, made of dry mud. He was informed by the traders that the gum is gathered during the months of January, February and March by collectors having vested rights in a certain portion of the forests. Long incisions are made vertically through the bark and the exuding gum allowed to harden, the trees not being injured by the process, the collections going on from year to year. *Gedda gum,* sometimes spoken of as an Egyptian gum, enters commerece through Geddah, or Jiddah, on the Arabian side of the Red Sea. It seems to be the same as *Mecca* or *El Wisch* or *Aden gums,* which are sometimes spoken of as Egyptian gums, but are probably produced in the triangular peninsula which forms the eastern extremity of Africa.

The best gum arabic is obtained near Khordofan from cultivated trees which are tapped from February to March. Strips of bark from 2 to 3 ft. long and 1 to 3 in. broad are torn from the trunks and larger branches, care being taken not to injure the cambium. The gum slowly exudes as a viscous liquid, collects in a tear at the base of the wound and gradually hardens. In from 2 to 4 weeks, depending upon the weather, the gum is collected by the natives who place the tears in leather bags which, when full, are emptied on a heap. The gum is later exposed to the bleaching action of the sun and garbled by native girls who remove bark and sand. It is then placed in sacks, carried by camel to railroad centers and consigned to Port Soudan for shipment.

Cairo and London are the chief markets of the world's supply of this drug.

Suakin gum, Talca or *Talha gum,* from *A. stenocarpa* and *A. Seyal,* is exceedingly brittle, and usually semi-pulverulent. It is a mixture of nearly colorless and brownish gums, is exported at Alexandria, and is sometimes termed *gum savakin.*

SENEGAL OR WEST AFRICAN GUM.—This commercial variety ranks second to the Khordofan gum. It is derived from *A. Senegal* and other species of *Acacia* growing in the Soudan and Senegal. It yields a good adhesive mucilage and is valuable for technical purposes. Some of the best qualities of Senegal gum are also adapted for certain pharmaceutical uses. It was introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade. St. Louis, at the mouth of the Senegal, and Portendie, considerably farther north, are the ports in which the commerce in gum chiefly centers. Immense forests exist in the interior, containing many species of the genus *Acacia,* all of which are said to yield gum, as is affirmed do also various trees belonging to other genera. The chief harvest begins in October and ends in December, although gum is also collected in March. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out and hardens in masses, which are often as large as a pigeon's egg, and sometimes as that of an ostrich. It is affirmed that the exudation is also largely caused by a parasitic plant, *Loranthus Acaciæ* Zucc., the gummy exudation freely oozing out at the point where the parasite penetrates the bark. (*Ph. Centralh.,* Aug., 1895.) Senegal gum is usually in roundish or oval unbroken tears, or in straight or curled cylindrical pieces of various sizes, in the finest grades whitish or colorless, but generally yellowish, reddish, or brownish-red. The pieces are generally larger than those of Khordofan gum, less brittle, fissured, and pulverizable, and breaking with a more conchoidal fracture. Vermiform tears are usually present and aid in diagnosing this variety. In recent years the commercial supply of gum Senegal has been a variable one. In 1911 the gum was extremely scarce, there was practically none on the market, owing to a failure of the crop. It is shipped from the Senegal river to Marseilles and Bordeaux, whence it enters the world's commerce.

According to the direction of the British Imperial Institute there are three qualities of Senegal gum as follows:

1. Gomme du bas du fleuve.
2. Gomme du haut du fleuve.
3. Gomme friable, Salabreda or Sadra beida.

INDIA GUM.—*Persian gum,* which is said to be sent from Persia to Assouan to be packed as genuine gum arabic, can be distinguished from the latter, which it closely resembles, by its not dissolving in water. Sickenberger thinks that it is the product of *Prunus bokharensis* or of *P. puddum. India gum* is not produced in India, but reaches Bombay from Aden and the Red Sea ports, and is almost certainly the product of the Soudan, being therefore identical with Egyptian gum. It occurs in India in two forms, "*Maklai,*" in large round tears or vermicular pieces, white, yellow or reddish, and much fissured; and "*Maswai,*" in fragments and vermicular pieces similar in color and fissuring to the other variety. It is often crudely adulterated before reaching Europe, especially with *Bassora gum,* distinguished by its insolubility in water. Of recent years various India gums have come into commerce in increasing quantities as substitutes for true gum arabic. India gum is brought to this country partly from Calcutta or Bombay, and partly by way of England. It usually comes in large cases. We have seen a parcel said to have come directly from the Red Sea, enclosed in large sacks made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size. This India gum should not be confused with *India gum Tragacanth,* which is called simply by the name India gum in the confectionery and ice cream trades where it is used as a filler and to give bulk and firmness; nor with *India gum of the Br.* (See *Gummi Indicum.*)

During 1924, approximately two-thirds of all the Acacia imported into the United States came direct from Egypt, being shipped for the greater part through Cairo from Khartoum, Khordofan, El Obeid and Omdurman. The other third was imported from London with the exception of an occasional shipment from Bordeaux, Marseilles, Hamburg, Morocco and Bombay.

SUBSTITUTES FOR GUM ARABIC ARE: *Amrad, Amra* or *Oomra Gum.*—A name applied to various East Indian gums having a reddish color and being in more or less irregular stalactitic pieces. (See *U. S. D.,* 19th ed., p. 4.) For description of Ghatti gum see *Gummi Indicum.*

Small quantities of gum are produced in India by a large number of trees often having no botanical relations with the Acacias. For an account of these gums see *Pharmacographia Indica,* vol. i.

Under the names of *Brazilian gum, Para gum,* and *gum angico,* large quantities of a gum occurring in large dark-amber or dark-brown glossy drops, soluble in water, are occasionally found in commerce. It is said to be the product of *Acacia Angico* Mart. Its mucilage is very adhesive, but usually too dark in color for pharmaceutical purposes. It must be distinguished from the gum resin often known as *Brazilian gum,* which is said to be obtained from *Hymenæa courbaril,* and is used in making varnishes.

Chagual or *Magyey gum* of Chili occurs in hollow cylindrical pieces from 0.2 to 1.5 cm. in thickness, occasionally having the form of stalactites or irregular tubers. On their inner surface they are longitudinally streaked, while their outer surface is usually numerously fissured, the fissures penetrating deeply toward the interior. In the absence of these, the pieces are of glassy brightness, transparent, and of very dense structure internally. The color varies from colorless, through yellowish and brownish to a tolerably deep brown, isolated pieces being almost black. According to the experiments made by Guehm, the commercial drug is scarcely fitted for technical use as a gum, but the clear pieces when made into a concentrated mucilage by prolonged heating answer the purposes of the calico printer well. *Puya chilensis, P. lanuginosa,* and *P. lanata* are commonly said to be the sources of the gum, though the researches of Hartwich make this uncertain. The exudation is asserted to be the result of the bite of a caterpillar, *Kastina elegans.* (*Zeit. Oest. Apoth. Ver.,* Aug. 1, 1896.)

Specimens of gum arabic are sometimes found in commerce, which are soluble in water with difficulty. According to Köchlin, if ten parts of such gum, fifty parts of water, and three parts of a 12 per cent. solution of hydrogen dioxide be heated together for two or three hours, the gum is rendered easily soluble. (*Nat. Drug.,* 1894, 176.) Related to the acacia gums are *wood gum,* from the wood of foliage trees, yielding xylose on hydrolysis; *cherry gum,* the gum of cherry and almond trees, yielding β-arabinose on hydrolysis; *peach gum,* from the peach tree, yielding arabinose and galactose on hydrolysis; *barley gum,* obtained in the nitrogen-free extractive material of cereals, yielding galactose and xylose.

Thos. Maben (*P. J.,* March 1, 1890, p. 717) gives the following method of testing mucilage obtained from various gums sold for gum arabic as the best that he has been able to devise after much experimentation. Two or three drops of the mucilage prepared from the gum are placed on a glass or porcelain slab, and one or two drops of the following reagents added; these are then stirred together with a glass rod and the results compared. In the case of borax, acacia mucilage at once agglutinates or hardens into a gummy mass, similarly with basic lead acetate and ferric chloride, while it gelatinizes or forms a softer mass with potassium silicate. Similar reactions are given by the Senegal gums, the Indian Amrad gums, white Barbary, white and brown Cape, and Geddah gums. Barbary brown and Amrad give a jelly only with borax, otherwise they react as acacia. Australian gum agglutinates with borax, but only gelatinizes with basic lead acetate, and has no reaction with ferric chloride and potassium silicate. Brazilian gum has no reaction with potassium silicate, but gelatinizes with borax and ferric chloride and slightly with basic lead acetate. Ghatti gum gelatinizes with all four reagents, but in a slight degree only with potassium silicate. Oomra gum reacts similarly to acacia, except that it is entirely unaffected by basic lead acetate, and forms a softer jelly with ferric chloride. There are, of course, shades of difference in the various reactions which cannot be indicated by these terms, but, generally speaking, a fair idea is given of the nature of the gum.

It has been proposed to change the arabinic acid of the sugar beet, by the method of Scheibler, into metarabinic acid, as the foundation of a true artificial gum arabic, but the *artificial* gums of the market have no such close chemical relation with the natural gum; many of them are mixtures of various substances, others are produced from starch by the action sulphuric acid or by other means. *Universal gum,* a patented product obtained from potato starch, has been highly commended for the permanency and adhesiveness of its mucilage, but is said not to act well as an emulsifier; it is essentially a form of dextrin. Gelatin is sometimes added to acacia as an adulterant; formaldehyde has been recommended by Trillet (*Ph. Post,* 1899, 629) as an agent for its detection. (See also *Proc. A. Ph. A.,* 1900, 643.)

Description and Physical Properties.—"*Unground Acacia.*—In spheroidal tears up to 32 mm. in diameter or in angular fragments; color, yellowish-white to light amber; translucent; very brittle, the fractured surface glassy and occasionally iridescent; almost odorless; taste, mucilaginous.

"*Powdered Acacia.*—White; in angular microscopic fragments with but slight traces of starch or vegetable tissues present. Acacia is insoluble in alcohol, but almost completely soluble in twice its weight of cold water, the solution being acid to litmus paper.

"Add 0.2 cc. of basic lead acetate T.S. to 10 cc. of a 10 per cent. cold aqueous solution of Acacia: a gelatinous precipitate is produced. Add 0.1 cc. of ferric chloride T.S. to 10 cc. of a 2 per cent. aqueous solution of Acacia; no blackish coloration or blackish precipitate is produced (*tannin-bearing gums*). An aqueous solution of Acacia does not give a bluish or reddish color with iodine T.S. (*starch or dextrin*)." *U. S.*

"When dissolved in an equal weight of *water,* the solution is not glairy, and after admixture with more *water,* yields no gummy deposit on standing. An aqueous solution (1 in 10) exhibits slight lævorotation (absence of dextrin, certain sugars, etc.). 10 millilitres of the same solution are not precipitated by *solution of lead acetate;* are not, after previous boiling and cooling, colored blue or brown by 0.1 millilitre of *N/10 solution of iodine* (absence of starch and dextrin), or bluish-black by *T. Sol. of ferric chloride* (absence of tannin). Ash not more than 4 per cent." *Br.*

The commercial gum arabic contains 15 per cent. of water and 3 per cent. of ash, consisting almost entirely of calcium, potassium and magnesium carbonates.

The gum dissolves slowly, at ordinary temperature, in twice its weight of water, forming a thick glutinous liquid of distinctly acid reaction. It is insoluble in alcohol, ether, and the oils. One hundred parts of 22 per cent. alcohol, by volume, dissolve 57 parts of gum, diluted alcohol containing 40 per cent. alcohol takes up 10 parts, and 50 per cent. alcohol only 4 parts (Flückiger).

Constituents.—Gum arabic is composed essentially of the calcium salt of *arabin* or *arabic acid* which is obtained by adding hydrochloric acid to the aqueous solution and precipitating with alcohol. O'Sullivan says that arabin contains an acid nucleus which he has named *l-arabinosic acid* to which he gives the formula $C_{23}H_{28}O_{22}$ and further states that arabin is a compound of this nucleus with *arabinan* and galactan. Upon complete hydrolysis there is produced *arabinose,* galactose and arabinosic acid. The arabin (or arabic acid) may also be prepared by placing a solution of gum, acidulated with hydrochloric acid, on a dialyzer, when calcium chloride will diffuse out, leaving behind solution of arabin.

Arabin has a decided tendency to form acid salts. Concentrated nitric acid forms with it nitro-compounds; diluted nitric acid, on the other hand, gives rise to mucic and saccharic acids, together with oxalic and a little tartaric acid. Kiliani (*Ber. d. Chem. Ges.,* 1887, 339) first established the presence of arabinose which is one of the pentoses. These are not fermentable, and, on prolonged boiling with diluted hydrochloric acid, lose the elements of water and yield furfurol. Neutral lead acetate does not precipitate an aqueous solution of gum arabic, but the basic acetate forms, even in a very diluted solution, a precipitate.

Prolonged heating of the dry gum causes it to change readily into *metarabic* (*metagummic*) *acid,* which is identical with the *cerasin* found in the beet and in cherry gum. Sulphuric acid will also change arabic into metarabic acid. 25 Gm. pure gum arabic are covered with 50 cc. strong alcohol, 10 cc. water, and 5 cc. sulphuric acid, and allowed to stand twenty-four hours. On pouring off the fluid, and washing the residue with alcohol and with water, metarabic acid remains behind as a voluminous mass, which dries to a white, tasteless, and odorless powder of acid reaction. The *metapectic acid* which is prepared by Scheibler (*B. Chem. G.,* 1873, p. 612) from the sugar beet is identical with metarabic acid.

The similarity of the reaction and composition of arabinose and galactose (from sugar of milk by inversion) led Kiliani to assert the identity of these two varieties of sugar, but later studies by himself, Claesson, and Scheibler have shown that they are distinct. Thus, galactose is fermentable, while arabinose is not; galactose yields mucic acid when oxidized with nitric acid, and dulcite when reduced with sodium amalgam, while arabinose does not yield either; the fusing point of the crystallized galactose is given at 142° to 144° C., while that of arabinose is 160° C.; galactose yields with phenylhydrazin a light yellow compound, fusing at 170° to 171° C., while arabinose forms a brownish-yellow compound, fusing at 157° to 158° C. (Scheibler, *B. Chem. G.,* xvii, 1731.)

Gum arabic undergoes no change by age, when kept in a dry place. Its concentrated aqueous solution remains for a considerable time unaltered, but ultimately becomes sour, from the production of acetic acid. The disposition to sour is increased by employing hot water in making the solution. The tendency of a weak solution to become moldy is said to be obviated by adding a few drops of sulphuric acid, and decanting from the calcium sulphate deposited. (*A. J. P.,* 1872, 353.) Solution of gum arabic does not ferment upon the addition of yeast, saliva, or gastric juice; the addition of chalk and cheese, however, starts a fermentation which gives rise to lactic acid and alcohol, but not to mannite or glycerin. The addition of a solution of gum to an acidified albumin solution causes a precipitate, which disappears on further addition of gum, but the solution will then curdle and become flocculent on application of heat. Gum may be distinguished from dextrin by the following tests: 1. Gum contains no dextroglucose, which, however, is present in dextrin, and may be recognized by the copper test. (See *Alkaline Cupric Tartrate Volumetric Solution,* Part III.) 2. Gum contains a lime compound; hence its solution is rendered milky by oxalic acid, while a solution of dextrin remains almost clear. 3. Gum gives a slimy, yellow deposit when its solution is mixed with a neutral ferric salt.

J. Henry Schroeder examined twelve specimens of powdered acacia, and states that dextrin is not frequently used as an adulterant, and that if in using the alkaline cupric tartrate test the heat be prolonged during twenty minutes, a well defined reduction was produced even when pure Senegal gum was used. (*A. J. P.,* 1897, 195.) R. G. Shoults (*A. J. P.,* 1900, 267) supplemented the conclusions of Schroeder and proposed to use the difference in rotatory power of acacia and dextrin as a test. He found a solution of pure acacia to have a lævorotatory power of –18°, while one of dextrin was dextrorotatory varying to the extent of from +120°

to +138°. This method of testing the presence of dextrin may be replaced by the simpler one with the microscope. (See also Kebler's paper, *Am. Drug.*, 1901, 343.) The following test is given in the *Ph. Post,* 1894, 563. Add 3 cc. of a solution consisting of 15 drops of solution of ferric chloride, 15 drops of a saturated solution of potassium ferrocyanide, 5 drops of HCl (1–125), and 60 cc. of water to a 20 per cent. solution of the gum. If the gum arabic is pure, it will remain a clear yellow for from eight to ten hours. If there is dextrin present, the color changes to blue.

According to Roussin (*J. P. C.* (4), vii, 251), gum arabic and dextrin may be separated by means of ferric chloride which precipitates only the former. For this separation 1 Gm. of the material to be tested is dissolved in 10 cc. of water, the solution mixed with 30 cc. of proof spirit, 4 drops of ferric chloride solution (containing 26 per cent. of the anhydrous chloride) added, followed by a few decigrammes of powdered chalk; after stirring briskly the mixture is allowed to stand for a few minutes and filtered. If this filtrate becomes cloudy on the addition of strong alcohol it proves the presence of dextrin. If a quantitative estimation is desired, the precipitate containing the acacia should be washed with proof spirit and the washings added to the filtrate and then treated with strong alcohol which precipitates the dextrin. This mixture is allowed to stand for 24 hours, the spirituous liquid decanted and the precipitated dextrin dissolved in a small quantity of water and the resultant solution evaporated at 100° C. and the residue weighed. The first precipitate, resulting from the addition of the ferric chloride, which contains the gum arabic, should be dissolved in dilute hydrochloric acid. From this the arabin may be precipitated by strong alcohol; the precipitate, often being washed with alcohol, is then dissolved in water, the solution evaporated to dryness and the residue weighed.

C. W. Ballard (*J. A. Ph. A.*, 1920, p. 31) gives a comprehensive scheme for the identification of acacia and a number of other well known gums by the phenylhydrazine reaction. The reagent consists of 1 part of phenylhydrazine hydrochloride, 3 parts anhydrous sodium acetate, and 25 parts of water. The gum is dissolved in water (1 in 20) and united by boiling with HCl for 2 hours in a reflux condenser. Equal parts of the inverted gum solution and the reagent are heated to boiling for 1 hour and then allowed to cool slowly. The crystalline deposit is recrystallized if necessary. Characteristic crystalline forms were produced by each of the fourteen gums and mucilages which this author used in his work and the article contains illustrations of these crystals.

The properties above enumerated belong to gum arabic generally. There are, however, varieties with differences which deserve notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidity of its solution. Under this head may be included the *gomme blanche fendillée* of Guilbourt. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light, but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the unbroken pieces are somewhat opaque, each minute fragment is perfectly, transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medicinal use and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guilbourt has proposed for portions of this gum the name of *gomme pelliculée,* from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mammillary appearance on the surface. It is less transparent than the former variety, is less freely and completely dissolved by water, and forms a more viscid solution. It dissolves with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities have been ascribed to variable proportions of *bassorin* or *cerasin* associated with the soluble *arabin.* Between these two varieties there are insensible gradations, so that it is not always easy to classify specimens.

E. Bourquelot (*J. P. C.,* 1904, xix, 473, 474) states that acacia contains an active oxidizing ferment which renders it unsuitable for use in many pharmaceutical preparations, and that, notwithstanding the wide use of acacia as an excipient, it is possible that certain active ingredients may become altered in its presence. Nor is acacia the only gum which contains a ferment; myrrh, frankincense and bdellium also contain an oxydase. Among the substances stated as being incompatible with acacia are pyrogallol, morphine, vanillin, ordinary phenol, cresylol, ortho- and meta-xylol, thymol, carvol, *a*- and *b*-naphthol, pyrocatechol, guaiacol, phenols, lysol, cresols, acetylguaiacol, veratrol, creosol, eugenol, acetyleugenol, methylaniline, ethylaniline, paratoluidine, crude aniline, xylidine, *a*-naphthylamine, pyramidon apomorphine, eserine, adrenaline, isobarbaloin, caffeotannic acid, gallic acid and tannin. Paraxylenol, hydroquinone, resorcinol, anisol and phenetol do not appear to be affected. Nor is the action confined to chemical substances; acacia is incompatible with the opium and Calabar bean products, suprarenal extract, aloetic preparations, and all substances flavored with vanillin, tannin-containing extracts, such as those of rhatany, catechu, and rhubarb; fluidextract of viburnum prunifolium, and kola preparations. Obviously, in cases where mucilage of acacia is concerned, this oxidizing action may be eliminated by heatng the liquid to 100° C., and thus destroying the enzyme.

Impurities and Adulterations.—As gum arabic is usually collected in huge piles at Khartoum before being shipped to Port Soudan the sand and impurities are likely to sift to the bottom. As a consequence the first orders are likely to be filled with the cleaner article, while the latter containing the siftings may run as high as 4 per cent. of ash. The inferior grades are often mixed with, or substituted for, the better kinds, especially in powder.

The chief adulterant and substitute for acacia within recent years has been *Mesquite Gum,* from *Prosopis juliflora* (Fam. *Leguminosæ*), a plant indigenous to Mexico. It occurs in brownish to reddish-brown tears of variable size and differs from acacia in not precipitating from its aqueous solution when solutions of ferric chloride, lead sub-acetate or sodium borate are added.

Rarely flour or other starchy matter is fraudulently added to the powder, but may be easily detected by the use of the microscope and the blue color which it produces with tincture of iodine. In consequence of the impurities and difference in quality, gum arabic should generally be garbled. It is surprising what a good effect the removal of 1 to 2 per cent. of objectionable matter has upon the remainder of the drug.

Acacia is incompatible with strongly alcoholic liquids, solutions of ferric chloride and lead subacetate, and strong solutions of sodium borate.

Uses.—Acacia is used in medicine chiefly as a demulcent. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed to dissolve slowly. It has been used as a food, but has very little if any nutritive value. In 1917 Bayliss suggested the use of a 7 per cent. solution of acacia for intravenous injection in the treatment of the posthemorrhagic conditions instead of the usual physiological salt solution. It was noted that after the use of the ordinary saline solution fluid escaped from the blood vessels so rapidly that the beneficial effects were too transitory to be of any practical value. This is generally attributed to the non-colloid nature of the salt solution; Bayliss after considerable experimentation finally recommended a 7 per cent. solution of acacia. The method has been attacked, especially on the grounds of possible anaphylactoid reactions or injurious effects on the kidney, but has, on the other hand, been highly praised by a number of surgeons. For references to the literature on this subject see *J. A. M. A.*, 1922, lxxviii, pp. 730, 1885 and 1897. It is essential for this purpose that only acacia in clear, colorless lumps be used. In pharmacy, gum arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered gum arabic are used, one a coarse powder called *granulated,* the other *finely dusted.* The granulated dissolves more readily in water, according to Hager, because it has lost during desiccation only two per cent. of moisture, while in preparing the "finely dusted" powder the high heat necessarily used to thoroughly dry it drives off ten per cent. of water. Its easy solubility and absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc.

ACACIÆ CORTEX. Br.

ACACIA BARK

"Acacia Bark is the dried bark of Acacia arabica, *Willd.,* and also the dried bark of Acacia decurrens, *Willd.;* obtained from wild or cultivated trees not less than seven years old, and, after being dried, kept for one year before use." *Br.*

Wattle Bark; Black Wattle; Babul Bark Neb-neb.

The Acacias are known not only for their gums, but a number of them contain large quantities of tannin and hence are used in tanning. Among the latter are the so-called wattle barks of Australia, and also catechu. The chief of the Australian trees is the black wattle (*A. decurrens*), the bark of which yields from 24 to 42 per cent. of tannin, and is employed as an astringent. More recently *A. arabica* has been similarly used in East Africa. It is a tree indigenous to India, Arabia and Africa.

Characters. "Bark of *A. arabica* hard and woody, rusty brown, and tending to divide into several layers. Outer surface of the older pieces covered with thick blackish periderm, rugged, fissured longitudinally and transversely. Inner surface red, longitudinally striated and fibrous. Taste astringent and mucilaginous."

"Bark of *A. decurrens* usually in curved or channelled pieces, 1.5 to 3 mm. thick. External surface greyish-brown, darkening with age; often with irregular longitudinal ridges, and, sometimes, transverse cracks. Inner surface reddish-brown, longitudinally striated; fracture irregular and coarsely fibrous, freshly fractured surface pale. Slight tan-like odor; taste astringent." *Br.*

Acacia bark owes its medicinal properties to the tannin it contains. It is used as an astringent in *diarrheas,* being usually employed in the form of a decoction (1:16), in *doses* of one-half to two fluidounces (15–60 cc.).

ACETANILIDUM. U. S., Br.

ACETANILID Acetanil. [Antifebrin]

"Monoacetyl aniline [$C_6H_5NH.CH_3CO$]." *U. S.* "Acetanilide, C_8H_9NO, may be obtained by the interaction of glacial acetic acid and aniline." *Br.*

Acetylamidobenzene, Phenylacetamide; Acétanilide, *Fr, Cod.*; Acetanilidum, *P. G.*; Antifebbrina, *It.*; Acetanilida. *Sp.*

Preparation.—Acetanilid is made, according to Yvon, as follows: 372 grammes of pure aniline and 240 grammes of glacial acetic acid are heated for four hours, to the boiling point, in a flask provided with a reversed condenser; the excess of both ingredients is then distilled off on a sand bath, this being completed when the temperature reaches 260° C. The cooled, congealed residue is crude acetanilid, which may be purified by sublimation or, better, by repeated crystallization from water.

This process has been criticized as not suitable for manufacturing acetanilid of pharmaceutical quality on account of the high temperature attained and the length of time of heating which yields a highly colored crude product difficult to purify.

It is found better on the large scale to mix the aniline and glacial acetic acid (500 lbs. each) in a steam jacketed enamelled still of 150 gallons capacity and to heat to 120°–125° C. for 8 or 9 hours, regulating the heat so that practically no vapor passes over into the condenser.

The progress of acetylation is followed by frequent tests for uncombined aniline. When the test for aniline is negative, usually in from 10 to 12 hours, the excess of acetic acid is distilled off under a vacuum. The residue is then blown into 200 gallons of water and allowed to cool. The crude acetanilid is centrifuged and recrystallized from boiling water, about 1000 gallons being required, using animal charcoal as a decolorizing agent. The mother liquors from both the centrifuging and crystallizing operations are used in succeeding batches.

The yield is about 400 Gm. It may also be prepared by acting on aniline with acetyl chloride (Gerhardt), or by heating aniline with acetamide (Kolbe). The sublimed salt is whiter and lighter than that obtained by crystallization from water, which has the appearance of boric acid. For Walters' method of preparing acetanilid, on a small scale, see *Bull. Pharm.*, 1899, 53.

Description and Physical Properties.—"Colorless, shining, crystalline leaflets, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Acetanilid is soluble in 190 cc. of water, 3.4 cc. of alcohol, 3.7 cc. of chloroform, 17 cc. of ether, 4 cc. of acetone, 47 cc. of benzene, and in about 5 cc. of glycerin, at 25° C. One Gm. is soluble in 20 cc. of boiling water and in 0.6 cc. of boiling alcohol. It is slightly soluble in petroleum benzin.

"Acetanilid melts between 113° and 115° C. Boil about 0.1 Gm. of Acetanilid with 5 cc. of sodium hydroxide T.S.: the characteristic odor of aniline becomes noticeable. Add 1 cc. of chloroform, and heat the mixture: the disagreeable odor of phenylisocyanide (a poisonous substance) is evolved. Boil about 0.1 Gm. of Acetanilid for several minutes with 2 cc. of hydrochloric acid: a clear solution results, which, when mixed with 3 cc. of an aqueous solution of phenol (1 in 20) and 5 cc. of a filtered, saturated solution of chlorinated lime, acquires a brownish-red color which becomes deep blue upon supersaturation with ammonia water. Bromine T.S. produces a white, crystalline precipitate in a saturated aqueous solution of Acetanilid.

"Ash: not more than 0.05 per cent. Shake 1 Gm. of Acetanilid with 20 cc. of distilled water for two minutes and filter: the filtrate is neutral to litmus paper. Add 5 drops of ferric chloride T.S. to 5 cc. of the filtrate: the color does not differ from that produced by adding 5 drops of ferric chloride T.S. to 5 cc. of distilled water (*aniline salts*). The solution of 0.5 Gm. of Acetanilid in 5 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*)." *U. S.*

"Colorless, glistening lamellar crystals; inodorous; taste slightly pungent. Melting point 113° C. Soluble in 210 parts of *water*, and in 4.2 parts of *alcohol* (90 per cent.); soluble in *ether*, and in *chloroform*. Heated with *solution of sodium hydroxide* the odor of aniline is given off, and if the liquid is then warmed with a few drops of *chloroform* the unpleasant odor of phenyl isocyanide is developed. An aqueous solution mixed with *solution of bromine* gives a yellowish-white precipitate (distinction from phenacetin). Forms a colorless solution with cold *sulphuric acid* or with cold *nitric acid*. A cold saturated aqueous solution does not affect *solution of litmus* (absence of free acid), and is not affected by *T. Sol. of ferric chloride* (absence of phenazone, and salts of aniline). Ash not more than 0.1 per cent." *Br.*

Ritsert (*Ph. Ztg.*, 1890, 306) believes that the difference in melting point of acetanilid given by various writers is due to the almost constant presence of toluidine in aniline, and the production of acettoluids which have the following melting points: *ortho*, 170° C.; *meta*, 65.5° C.; and *para*, 147° C. A very important reaction, by which the presence of acettoluid may be detected in acetanilid, is in the use of a boiling solution of potassium permanganate. If the acetanilid be pure, it is not altered, and does not reduce the permanganate, but acettoluid, if it be present, is oxidized to acetamidobenzoic acid with reduction of the permanganate. Of a number of samples of acetanilid examined, in only one was the reduction slight, while all the others showed a decided reduction.

Methods for detection of acetanilid in mixtures of antipyretic drugs are frequently needed. R. Miller (*A. J. P.*, 1917, lxxxix, 156) outlines a rapid approximate method of determining phenacetine when mixed with acetanilid, which depends upon the yellow color produced when phenacetine is acted upon with nitric acid. The mixture of the antipyretics is dissolved in methyl alcohol and nitric acid added, a yellow color is produced, proportional to the amount of phenacetine present.

A method of assay for mixtures of acetanilid with various other synthetic remedies such as phenacetin, salol, etc., is suggested by A. D. Powell, *C. D.*, 1918, p. 1002.

Acetanilid is incompatible with alkalies (which liberate aniline) and when it is triturated with phenol, thymol, and many other organic drugs it forms a eutectic mixture which liquefies.

Uses.—Acetanilid is one of a numerous group of compounds which yield in the system paramido-phenol. Since these drugs owe their therapeutic virtues to the formation of this body the action of all of them is essentially the same. They differ, however, in the brusqueness of their effects according to the rapidity with which the paramido-phenol is formed from them.

The most striking actions of acetanilid are upon the heat regulating mechanism and the pain perception. The maintenance of the body temperature at a constant level is due to a delicate balance between the amount of heat generated in the system and that which is thrown off. The source of the bodily heat is chiefly from the oxidation of hydrocarbons in the organism; the dissipation of heat is accomplished partly by direct radiation from the skin and partly through the evaporation of the sweat. It is evident that the body temperature can be lowered either by diminishing oxidative processes or by increasing the rapidity in the dissipation of heat. There has been a great deal of experimental research to determine which of these functions acetanilid and the other antipyretics affected, but the conflicting results of various experimenters upon whether these drugs act upon heat formation or heat dissipation, and the observations of Stuhlinger (*A. E. P. P.*, 1899, xliii, p. 167) of the difference in the effects on heat dissipation between rabbits and guinea pigs, as well as clinical experience strongly suggests that the action of these antipyretics is not due primarily to effects either upon heat dissipation or heat formation but to some sort of narcotic action which lessens the irritability of the heat mechanism so that it does not respond to the irritation produced by poisons circulating in the blood. Hashimoto (*A. E. P. P.*, 1915, lxxviii, p. 414) has brought forward experimental evidence that the antipyretics lessen the irritability of the heat centers in the corpus striatum without, however, paralyzing it. It would seem that there is produced in the body in certain infections some poison which irritates the thermoregulator center and leads to a higher level of body temperature; the tendency of the system to maintain the temperature at a constant level is not lost but the level is higher than in health. It seems probable that acetanilid, perhaps by some sort of narcotic effect, lessens the irritability of the heat-regulating mechanism so that it does not respond to the irritation produced by poisons circulating in the blood. It is worthy of note that these drugs do not affect the body temperature in healthy persons unless given in poisonous quantities. Of the manner in which acetanilid lessens the sensibility towards pain, we are entirely ignorant. Barbour (*Proc. Soc. of Exp. Biology and Med.*, 1919, xvi, and *Proc. Nat. Acad. Sciences*, 1920, vi, p. 136) has recently brought forward a theory that the antipyretic action of the coal tar series is due to an effect upon carbohydrate metabolism whereby they increase the amount of blood sugar; this leads in turn to a relative hydremia which, through overfilling of the blood vessels, promotes heat dissipation.

In ordinary dose acetanilid has no demonstrable action upon the respiration or circulation in the lower animals, although in very large quantities it acts as a depressant to the heart. (Hale, *J. P. Ex. T.*, 1909, i, p. 185.) It appears also to be feebly depressant to the motor centers in the cord. When used continuously or given in toxic quantity, it acts upon the hemoglobin of the blood producing a new compound known as methemoglobin, which does not yield its oxygen to the tissues with sufficient readiness to maintain their function.

Locally acetanilid is mildly antiseptic and to some degree anesthetic.

Acetanilid is used in medicine chiefly as an analgesic or as an antipyretic. As a pain relieving drug its greatest value is in cases of *neuralgia* whether of the head or other portions of the body. It is, however, an agent of much usefulness even in those pains in which there are actual anatomical lesions in the nervous system, such as *neuritis* or crises in *locomotor ataxia*. When, however, the pain is due to conditions outside of the nervous system, although it may enhance the potency of the opiates, by itself it is of little service.

There has been a great deal of difference of opinion as to the advisability as to the use of antipyretic drugs for the purpose of lowering *fever* temperature. One of their great disadvantages is a liability of overaction; at times they produce such a sudden or excessive change in body temperature as to lead to a condition of collapse.

Locally acetanilid has been used as a dusting powder in various types of *ulcers*, but its use is not free from danger and it does not appear to have any great advantage over a number of other safer remedies for this purpose.

Toxicology.—Two distinct types of acetanilid poisoning must be recognized, one in which the symptoms are caused by a single large dose, and the other by repeated use of the drug over long periods of time. Under ordinary circumstances acetanilid is a relatively safe remedy, but there are not a few persons who possess an idiosyncrasy towards the drug and are liable to show toxic symptoms after doses which cannot be regarded as excessive. In poisoning from single doses of acetanilid there is marked fall of the body temperature with the symptoms of collapse, rapid feeble pulse, cold, clammy skin, more or less drowsiness or even coma, sometimes tinnitus aurium, or mydriasis; there is frequently a peculiar eruption of the skin resembling that of measles; sometimes there is cyanosis, although this is less common than in the more chronic types of intoxication.

The frequency with which the laity employ various mixtures containing acetanilid for the relief of the minor discomforts of life is a serious danger to the welfare of the community. In the first place, acetanilid is to be ranked among the habit-forming drugs; there are a number of well-authenticated instances on record of acetanilid habit. In the second place the prolonged use of the drug leads to chemical changes in the blood, as has been pointed out above. When acetanilid is taken regularly and frequently these changes in the blood are frequently manifest, even to the casual observer, by a peculiar dusky cyanotic color of the skin and especially of the lips. Probably because of the diminished oxygen carrying power of the blood there is a tendency towards degenerative changes in various organs, especially the heart muscle, and sudden death from slight overexertion is liable to occur.

Dose, three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Pulvis Acetanilidi Compositus, *N. F.*

ACETONUM. U. S., Br.

ACETONE. Aceton. [Dimethyl-ketone]

"Acetone contains not less than 99 per cent. of $CH_3.CO.CH_3$," *U. S.* "Acetone, or dimethylketone, C_3H_6O, may be obtained by the dry distillation of calcium acetate, or barium acetate." *Br.*

Pyroacetic Spirit; Acétone, Ether (Esprit) pyroacétique *Fr.;* Acetone, Essiggeist, Mesitalkohol, *G.;* Acetone, Chetone Metilacetone, *It.*

Preparation.—Acetone is found in small amount in normal urine, in blood, etc., and in larger amount in certain pathological conditions. It is produced during the dry distillation of sugar, gum, cellulose, etc., and therefore is always contained in crude wood-naphtha.

E. R. Squibb has also prepared it on a large scale by passing acetic acid vapor through a rotating iron cylinder heated to from 500° to 600° C., and containing pumice stone with precipitated barium carbonate. (*J. Am. C. S.*, 1895, 197.) It is made commercially by the dry distillation of calcium acetate at a temperature not exceeding 300° C. The crude acetone thus obtained is purified by digestion with quicklime and again distilled from sodium hydroxide. Acetone of even higher purity is obtained by a subsequent distillation from sodium sulphite.

The outbreak of the World War brought a large demand for acetone as a solvent in the smokeless powder industry which could not be satisfied by the facilities of the wood distillation industry. Acetone was produced to meet this demand by a process of fermentation known as the Fernbach process. A special ferment is employed which produces a mixture of acetone and butyl alcohol from starch. More than 300 tons per month were made in Canada and the U. S. alone during the latter part of the war, by this method.

Description and Physical Properties.—"A transparent, colorless, mobile and volatile liquid, having a characteristic odor. It is inflammable. Acetone is miscible without cloudiness with water, alcohol, ether, chloroform, and most volatile oils.

"Specific gravity: about 0.790 at 25° C. It boils between 56° and 58° C., but volatilizes even at low temperatures. Add 1 cc. of sodium hydroxide T.S. to 1 cc. of an aqueous dilution of Acetone (1 in 200), warm the mixture, and add a few cc. of iodine T.S.: a yellow precipitate of iodoform is formed at once. Mix 1 cc. of the same Acetone dilution with 5 drops of sodium nitroprusside T.S. and 2 cc. of sodium hydroxide T.S., and add a slight excess of acetic acid: a deep red liquid is produced which develops a violet tint when diluted with several volumes of water.

"Acetone diluted with an equal volume of distilled water does not affect the color of blue or red litmus paper previously moistened with water. Evaporate 50 cc. of Acetone in a dish on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.002 Gm. Mix 20 cc. of Acetone with 0.1 cc. of tenth-normal potassium permanganate in a clean, glass-stoppered bottle: the pink tint produced does not wholly disappear in less than fifteen minutes (*empyreumatic substances*).

"Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

"A colorless, transparent, mobile and volatile liquid. Characteristic odor; taste pungent and sweetish. Forms clear mixtures with *water, alcohol* (90 per cent.), *ether* and *chloroform* in all proportions. Specific gravity 0.795 to 0.798. Not less than 95 per cent. distils between 55° and 57° C. Leaves no residue when evaporated on a water-bath. 10 millilitres, to which a few drops of *solution of phenolphthalein* have been added, require not more than 1 drop of *N/1 solution of sodium hydroxide* to produce a permanent pink coloration. 20 millilitres do not completely decolorize 0.1 millilitre of *N/10 solution of potassium permanganate* within fifteen minutes (limit of readily oxidizable impurities). Yields a clear mixture with an equal volume of *petroleum spirit* (limit of water)." *Br.*

Distilled with water and chlorinated lime, it yields nearly 200 per cent. of its weight of chloroform, and hence largely used in the manufacture of this substance, both in this country and in Germany. In the presence of an alkali, iodine converts it into iodoform, so that a trace of acetone in methyl alcohol can be detected by iodoform formation. This reaction is taken advantage of in the quantitative determination of acetone. It may also be determined by Strache's phenyl-hydrazine method. (*Zeit. An. Chem.*, 1892, p. 573.)

Reagents for detecting acetone in the urine are described under *Diagnostic Reagents,* Part III.

Acetone oil, largely a mixture of higher ketones, obtained as a by-product in the manufacture of acetone and suggested by Lang as an addition to alcohol and spirits to denaturize them, cannot be used on a large scale as pointed out by Klar, as the commercial supply would probably be insufficient. (*Chem. News,* 1899, 205.)

Assay.—"Determine the exact weight of a glass-stoppered weighing bottle containing 15 cc. of distilled water, add about 1 cc. of Acetone, and again weigh accurately. Transfer the contents of the bottle to a 1000 cc. graduated flask, rinse the weighing bottle with several portions of distilled water, and add the rinsings to the flask. Fill to the mark with distilled water, and mix thoroughly. Place 25 cc. of normal sodium hydroxide in a 250 cc. glass-stoppered flask, add exactly 25 cc. of the Acetone solution and 35 cc. of tenth-normal iodine, with constant agitation of the flask, and allow the mixture to stand for fifteen minutes. Add 26 cc. of normal hydrochloric acid, and at once titrate the residual iodine with tenth-normal sodium thiosulphate, adding starch T.S. as indicator when the liquid is nearly decolorized. Conduct a blank test with the same quantities of the reagents, and subtract the quantity of tenth-normal iodine consumed in the blank test from that consumed in the assay. Each cc. of the difference, which represents the iodine consumed by the reaction with the Acetone, corresponds to 0.0009677 Gm. of $CH_3.CO.CH_3$." *U. S.*

Uses.—Acetone is used chiefly as a solvent for fats, resins, and camphors, and was used as a menstruum for extracting oleoresins in the U. S. P. VIII. As a solvent it is particularly valuable in that it possesses the fat dissolving power of the immiscible solvents and the miscibility with water which makes it similar to alcohol. It is present in a number of the denatured alcohols of commerce, both in those intended for general use and in those used by special permit only. As a drug it has been employed locally to a certain extent in inoperable *carcinomata of the uterus* for the purpose of relieving hemorrhage and discharge. (Gellhorn, *Cb. Gyn.,* 1911, 1240.)

In a general way, the physiological effects of acetone seem to resemble those of alcohol. Salant and Kleitman (*J. P. Ex. T.,* 1922, xix, 293) have found that the intravenous injection of 1 cc. per kilo caused in the rabbit narcosis with primary stimulation and secondary depression of respiration and a fall in the blood pressure. Elimination is slow but its rate varies in different animals. In cats they detected it in the blood 24 hours after injection, but in dogs it had disappeared within 4 hours. The toxicity of acetone is not very high, as is shown not only by the experiments of Salant and Kleitman upon rabbits but also by the studies of Albertoni who found that *doses* of 15 to 20 Gm. of acetone produced no symptoms in man beyond slight narcosis.

Off. Prep.—Petroxolinum Iodoformi, *N. F.*

ACETPHENETIDINUM. U. S. (Br.)

ACETPHENETIDIN Acetphen. [Phenacetin]

"Monoacetyl para-aminophenetol [$C_6H_4(OC_2H_5).NH.CH_3CO$ 1:4]." *U. S.* "Phenacetin or para-acet-phenetidin, $C_{10}H_{13}NO_2$, may be obtained by the interaction of glacial acetic acid and paraphenetidin." *Br.*

Phenacetinum *Br., P. G.;* Para-acetphenetidin, Para-ethoxyacetanilide; Phenacetin; Acet-Phénétidine, *Fr. Cod.;* Phénacetine, Para-acétophénétidine, Amide Acétique de l'amido-Phénétol, *Fr.;* Fenacetina, *It., Sp.*

The chemical relationship of this body to phenol is seen by an examination of its formula and the formulas of the intermediate compounds obtained as stages in its preparation.

Phenol, $C_6H_5.OH$, is converted into *nitrophenol,* $C_6H_4(NO_2)OH$. Only the paranitrophenol is available, and this is separated by distilling off the ortho-nitrophenol by steam distillation. The residual *paranitrophenol,* in the form of the sodium compound, is treated with ethyl chloride, when ethyl paranitrophenol or *paranitrophenetol,* $C_6H_4(NO_2)OC_2H_5$, is produced. This is now reduced by the action of hydrochloric acid and iron turnings to *paraphenetidin,* $C_6H_4(NH_2)OC_2H_5$ or the reduction may be carried out by the use of sodium sulphide. Glacial acetic acid then serves to introduce the acetyl group, and *para-acetamidophenetol* (phenacetin), $C_6H_4(NHC_2H_3O)OC_2H_5$, is obtained. It is also prepared commercially by starting with para-acetamino-phenol which is later subjected to ethylation by the use of ethyl bromide.

The crude phenacetin by either of these methods is purified by recrystallization from water or 90 per cent. alcohol, with the use of animal charcoal or sulphur dioxide as decolorizing agents.

Description and Physical Properties.—"White, glistening, crystalline scales, or a fine white, crystalline powder. It is odorless, has a slightly bitter taste, and is stable in the air. One Gm. of Acetphenetidin is soluble in 1310 cc. of water, 15 cc. of alcohol, 14 cc. of chloroform, and in about 130 cc. of ether, at 25° C. One Gm. is soluble in 82 cc. of boiling water and in 2.8 cc. of boiling alcohol. Acetphenetidin melts between 134° and 135° C. Boil about 0.1 Gm. of Acetphenetidin for one minute with 1 cc. of hydrochloric acid, dilute with 10 cc. of distilled water, cool, filter, and add a drop of potassium dichromate T.S. to the filtrate: a ruby-red color results.

"Ash: not more than 0.05 per cent. Shake about 1 Gm. of Acetphenetidin with 20 cc. of distilled water during two minutes, and filter: the filtrate is neutral to litmus paper. A mixture of about 0.005 Gm. of Acetphenetidin and 1 cc. of nitric acid develops a yellow color which becomes darker on standing. A solution of 0.5 Gm. of Acetphenetidin in 5 cc. of sulphuric acid is only faintly yellow (*readily carbonizable substances*). Boil 0.5 Gm. of Acetphenetidin with 10 cc. of distilled water for one minute, cool, filter, and add bromine T.S. to the filtrate, drop by drop, agitating after each addition until the solution remains permanently yellow: neither turbidity nor precipitation results (*acetanilid*). A mixture of 0.3 Gm. of Acetphenetidin with 1 cc. of alcohol and 1 drop of tenth-normal iodine does not acquire a red tint when diluted with three times its volume of distilled water and boiled (*paraphenetidin*)." *U. S.*

The British Pharmacopœia gives the following tests for phenacetin. "Small, colorless, glistening, scaly crystals. Inodorous; tasteless. Melting point 135° C. Very sparingly soluble in cold *water,* more freely in boiling *water;* soluble in 21 parts of *alcohol* (90 per cent.), the solution being neutral to *litmus.* 0.1 gramme boiled with 2 millilitres of *hydrochloric acid* for half a minute yields a liquid which, diluted with 10 times its volume of *water,* cooled and filtered, assumes a deep-red color on the addition of *solution of chromic acid. Sulphuric acid* dissolves Phenacetin without coloration. A cold saturated aqueous solution does not become turbid on the addition of *solution of bromine* (absence of acetanilide). A mixture of 0.3 gramme of Phenacetin with 1 millilitre of *alcohol* (90 per cent.) does not acquire a red tint when diluted with 3 times its volume *of water,* and boiled with 1 drop of *N/10 solution of iodine* (absence of paraphenetidin). No appreciable ash." *Br.*

The test with chromic acid will serve to distinguish it from acetanilid and exalgin; that with bromine water will indicate the absence of phenol and acetanilid, both of which will show a white turbidity, owing to the formation of difficultly soluble bromine derivatives. The presence of unchanged paraphenetidin may be detected by melting 2.5 Gm. of hydrated chloral in a test tube and adding 0.5 Gm. of the acetphenetidin to be tested. If pure, it will remain colorless; if paraphenetidin be present, it will become violet or reddish-blue in tint. For further information see a paper in *Proc. A. Ph. A.,* 1903, 180, on an examination of samples of commercial phenacetin by G. M. Beringer, and *Proc. A. Ph. A.,* 1903, 365, for a paper by L. F. Kebler on its history, methods of manufacture, and chemical constitution.

Acetphenetidin is incompatible with strong acids and alkalies, and also with oxidizing agents, such as chlorine, bromine, and iodine. It forms a liquid eutectic mixture when rubbed with chloral, phenol, etc. It conceals the fluorescence of dilute quinine sulphate solutions.

Uses.—Acetphenetidin, like acetanilid, yields in the body paramido-phenol and its physiological action and therapeutic effects are therefore essentially the same as those of acetanilid (*q. v*). Its action, however, is more gradual and more prolonged and it is less likely to give rise to undesirable symptoms. Enormous quantities of it can be administered to the lower animals without disturbances of the vital functions: H. C. Wood, Jr. (*U. M. M.,* July, 1900), found that 0.5 Gm. per kilo could be injected intravenously into the dog before the occurrence of serious disturbances of either respiration or circulation. In large quantities it is mildly depressant to the spinal cord. The relative safety of acetphenetidin as shown both by animal experimentation and clinical experience, is probably dependent upon the slowness with which it undergoes chemical change in the blood and consequent gradual formation of the active phenylamine. It is, however, capable of causing serious poisoning; we are cognizant of a case in which five powders of 2 grains each taken over an interval of ten hours, produced death in a baby one year old, and Hollopeter reports serious collapse from 22½ grains in a woman. Acephenetidin is useful as an antipyretic and analgesic in the same group of cases in which acetanilid is of service. It requires, however, somewhat larger doses to produce the same degree of action.

Dose, five to fifteen grains (0.32–1.0 Gm.).

ACETUM CANTHARIDINI. Br.

Vinegar of Cantharidin

Vinaigre cantharidé, *Fr.;* Cantharidin-Essig, *G.*

"Cantharidin, 1 gramme; Glacial Acetic Acid, 200 millilitres; Acetic Acid sufficient to produce 2000 millilitres. Dissolve the Cantharidin in the Glacial Acetic Acid with the aid of a water-bath; cool, and add sufficient Acetic Acid to produce the required volume." *Br.*

This preparation contains approximately the same proportion of cantharidin as the *Acetum Cantharidis* of the British Pharmacopœia, 1898. The latter was made by macerating and then percolating bruised cantharides with diluted glacial acetic acid.

Procter found that, by digestion at a temperature of 100° C., the active principle of the flies is readily taken up by official acetic acid, though a portion of the cantharidin is deposited upon cooling. (*A. J. P.*, xxiv, 299.) It would seem, therefore, that the vinegar of Spanish flies would be best prepared with the aid of heat; and, to a certain extent, this advantage is enjoyed in the present process.

Uses.—This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed in two or three hours by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate.

ACETUM SCILLÆ. U. S., Br.

VINEGAR OF SQUILL Acet. Scill.

Aceticum scilliticum; Meerzwiebel-Essig, *G.;* Vinaigre de scille, *Fr. Cod.;* Vinaigre scillitique, *Fr.;* Aceto scillitico, *It.;* Vinagre de escila, *Sp.*

" Squill, in coarse powder, 100 Gm.; Diluted Acetic Acid, a sufficient quantity to make 1000 cc. Macerate the squill with 900 cc. of diluted acetic acid during seven days with frequent agitation. Then strain the mixture, and wash the mass on the strainer with enough diluted acetic acid to make the strained liquid measure nearly 1000 cc. Heat this liquid to boiling, filter while hot, and when cold add sufficient diluted acetic acid to make the product measure 1000 cc." *U. S.*

" Squill, bruised, 1000 grammes; Acetic Acid, 1000 millilitres; Distilled Water, 3200 millilitres. Macerate for seven days; press and filter.

" *Tests.*—Specific gravity 1.070. 10 millilitres require for neutralisation not less than 10.8 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

The British preparation is of approximately twice the strength of the Acetum Scillæ of the British Pharmacopœia 1898 or of the U. S. P.

Vinegar of Squill may also be prepared by percolating the Squill with the diluted acetic acid after previous maceration with an equal bulk of the diluted acetic acid (this precaution being necessary in order to satisfy thoroughly its tendency to swell) and filtering through paper.

The process now official differs from that of the U. S. Pharm. of 1890 in directing the heating of the strained liquid to coagulate albuminous matter and filtering, so that when the vinegar is mixed with sugar and water, in making syrup of squill, a transparent syrup may be secured.

As vinegar of squill is apt to be injured by keeping, it should be prepared in small quantities, as wanted for use.

Uses.—Vinegar of squill is certainly inferior to the alcoholic preparations of this drug in its effects upon the heart and kidneys. It is used chiefly for making syrup of squill.

Dose, of the U. S. preparation, from fifteen to thirty minims (1–2 cc.), but the latter quantity would be apt to nauseate; of the Br., five to fifteen minims (0.3–0.9 cc.).

Off. Prep.—Syrupus Scillæ, *U. S., Br.;* Oxymel Scillæ, *N. F.*

ACETUM URGINEÆ. Br.

VINEGAR OF URGINEA Vinegar of Indian Squill

" Urginea, bruised, 1000 grammes; Acetic Acid, 1000 millilitres; Distilled Water, 3200 millilitres. Macerate for seven days; press and filter.

" *Tests.*—Specific gravity 1.070. 10 millilitres require for neutralisation not less than 10.8 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

Vinegar of Urginea was admitted to the Indian and Colonial Addendum of the British Pharmacopœia in 1900, but the strength was doubled approximately in the Br. Pharm., 1914. It is used to make syrup of urginea in the same way that vinegar of squill is used by the addition of sugar. It is to be regretted that the end product was not definitely stated in the above process, as some loss during expression cannot be avoided. Under these circumstances the requirement that the specific gravity shall be exactly 1.070 cannot always be met satisfactorily.

Dose, five to fifteen minims (0.3–0.9 cc.).

ACIDUM ACETICUM. U. S., Br.

ACETIC ACID Acid. Acet.

" Acetic Acid is an aqueous solution containing not less than 36 per cent. and not more than 37 per cent. of CH_3COOH." *U. S.* " Acetic Acid may be obtained by the destructive distillation of wood, and contains 33 per cent. by weight of hydrogen acetate, $HC_2H_3O_2$, and 67 per cent. by weight of water." *Br.*

Acetum Concentratum; Ethanoic Acid; Acide acétique, *Fr Cod.;* Acidum Aceticum Dilutum, *P. G.;* Essigsäure, *G.;* Acido acetico, *It., Sp.*

For account of this see under *Acidum Aceticum Glaciale.*

ACIDUM ACETICUM DILUTUM. U. S., Br.

DILUTED ACETIC ACID Acid. Acet. Dil.

" Diluted Acetic Acid is an aqueous solution containing not less than 5.7 and not more than 6.3 per cent. of $CH_3.COOH$." *U. S.* " Diluted Acetic Acid contains 5 per cent. by weight of hydrogen acetate, $HC_2H_3O_2$." *Br.*

Acetum Destillatum; Acide Acétique dilué, *Fr.;* Acetum, *P. G.;* Reiner Essig, Verdünnte Essigsäure, *G.*

See under *Acidum Aceticum Glaciale.*

ACIDUM ACETICUM GLACIALE.
U. S., Br.

GLACIAL ACETIC ACID Acid. Acet. Glac.

"Glacial Acetic Acid contains not less than 99 per cent. of CH_3COOH." *U. S.* "Glacial Acetic Acid contains not less than 98.9 per cent. by weight of hydrogen acetate, $HC_2H_3O_2$." *Br.*

Acidum Aceticum Concentratum; Radical Vinegar; Acidum Aceticum, *P. G.;* Acide acétique crystallisable, *Fr. Cod.;* Acide acetique concentré, Vinaigre glacial, Esprit de vinaigre, *Fr.*, Essigsäure, Eisessig, *G.;* Acido acetico concentrato, *It.*

Three strengths of acetic acid are now official in the U. S. and Br. Pharmacopœias. These are *Acidum Aceticum Glaciale,* of sp. gr. 1.047 to 1.050 at 25° C., *U. S.; Acidum Aceticum,* of sp. gr. 1.045, *U. S.,* at 25° C., and 1.044, *Br.,* at 15.5° C., and *Acidum Aceticum Dilutum,* sp. gr. 1.008, *U. S.,* at 25° C., and 1.007, *Br.,* at 15.5° C.

We shall consider these grades separately, in the order of their strength.

Acidum Aceticum Glaciale.—A process for this preparation was given in the British Pharmacopœia of 1864, but was not satisfactory, as the resulting acid was not truly glacial, and always contained sulphurous acid. The following modification of the process does, however, yield a pure product. Crystallized sodium acetate is in an iron dish in its own water of crystallization, dried out, again brought to fusion by increased heat, whereby, if the heat applied be not too strong, no acid is decomposed or vaporized. The anhydrous salt is then treated with half a molecule of sulphuric acid (for 82 parts anhydrous acetate 49 parts of strongest sulphuric acid), which, according to Mohr and Buchner, suffices, instead of twice the amount, usually employed. No sulphurous acid is liberated in this case. A process to be followed on a large scale, practically the counterpart of this, is given in the *U. S. D.,* 14th ed., p. 8.

Acetic acid of maximum strength may also be obtained by distilling acid potassium acetate at a heat between 199° C. and 299° C. One molecule of monohydrated acetic acid distils over, and neutral potassium acetate is left. The acid acetate may be formed by evaporating a mixture of the neutral acetate with an excess of aqueous acetic acid. In this process, the same potassium acetate serves repeatedly for conversion into acid acetate, and subsequent decomposition. This process is said to be employed by manufacturers on a large scale in some parts of the continent of Europe. It originated with Melsens. It is customary in the preparation of the very pure acid to construct the head of the still and the entire condensing system of pure silver.

Description and Physical Properties.—"A clear, colorless liquid, having a strong, characteristic odor, and a very pungent, acid taste. Glacial Acetic Acid is miscible with water, alcohol, and glycerin. Specific gravity: from 1.047 to 1.050 at 25° C.

"Congealing point: not below 14.5° C. It boils between 117° and 118° C. Glacial Acetic Acid responds to the reactions for acetates, page 440. It conforms to the tests for purity under *Acidum Aceticum* when diluted to that strength, except in the following respects: The pink color produced by the addition of 0.1 cc. of tenth-normal potassium permanganate to 2 cc. of Glacial Acetic Acid, which has been diluted with 10 cc. of distilled water and is contained in a glass-stoppered bottle, is not changed to brown within two hours (*readily oxidizable impurities*). Evaporate 20 cc. of Glacial Acetic Acid to dryness on a water bath, and dry to constant weight at 100° C: the weight of the residue does not exceed 0.002 Gm.

"Preserve in glass-stoppered bottles." *U. S.*

"At summer temperatures [about 15° to 20° C.] it is a clear, colorless liquid with a very pungent odor. Yields, when neutralised, the *reactions* characteristic of acetates. Crystallizes when sufficiently cooled, and does not entirely re-melt until the temperature rises above 14.7° C. 1 gramme diluted with 50 millilitres of *water* requires for neutralisation not less than 32.9 millilitres of *N/2 solution of sodium hydroxide.* Leaves no residue on evaporation, and yields no characteristic *reactions* for lead, copper, arsenic, chlorides, nitrates, sulphates, or sulphites. Does not immediately darken in color when neutralised with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 2 millilitres of Glacial Acetic Acid do not completely decolorize a mixture of three drops of *solution of potassium permanganate* and 10 millilitres of *water* within half a minute (limit of empyreumatic matter)." *Br.* The anhydride was first isolated by C. Gerhardt, who found it to be a limpid liquid, heavier than water, and having the constant boiling point of 138° C. Glacial acetic acid should be kept in carefully stoppered glass containers, as it otherwise loses strength.

The U. S. and Br. acids are identical in strength (99 per cent.) but the temperature at which the sp. gr. is taken is 25° C. in the U. S. and 15° C. in the Br. It possesses the property of dissolving a number of substances, such as volatile and fixed oils, camphor, resins, gelatin, etc. As it attracts humidity from the atmosphere, it should be preserved in well-stoppered bottles.

The percentage of water in glacial acetic acid is generally determined by titration or by taking the melting and congealing points. N. Schoorl discovered that a solubility test with iodine and carbon tetrachloride gives very close results. Carbon tetrachloride is soluble in water-free glacial acetic acid in all proportions and its solubility is affected in proportion to the amount of water present. Iodine is used to intensify the end point of the reaction. (*Ph. Wb.*, 1917, 945.) The official method is as follows:

"**Assay.**—Proceed as directed under the assay for acids, using about 2.5 Gm. of the Acid, accurately weighed, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$." *U. S.*

ACIDUM ACETICUM. *U. S., Br.* (sp. gr. 1.045, *U. S.*, 1.044, *Br.*). *Acetic Acid.*—This is the acid usually resulting from the purification of the crude acetic acid obtained by the destructive distillation of wood. It is the strength most useful to the apothecary, and is employed in making numerous pharmaceutical preparations. As this acid often has its source in acetic acid made by destructive distillation it will be proper to premise some account of the crude acid, called *pyroligneous acid.*

Wood, when charred, yields many volatile products, among which are an acid liquor, an empyreumatic oil, and tar containing creosote and some other proximate principles (see *Pix Pini.*) When the carbonization is performed in closed vessels, these products, which are lost in the ordinary process of charcoal burning, may be collected, and, at the same time, a large amount of charcoal be obtained.

Senff has furnished some comparative results in respect to the dry distillation of wood. It was found that when similarly distilled the yield by weight of crude acid, tar, charcoal, and gas from the most diverse species of wood does not essentially differ, but that the percentage of real acid in the crude acid obtained varies considerably, and in this respect the wood from orginary foliage trees compares favorably with that from needle-leaved trees; also that stem-wood yields more acid than branch-wood, that wood yields more acid than bark, and that sound wood yields more acid than unsound wood. (*B. Chem. G.*, 1885, xviii, p. 60.)

The following table gives the amounts of the various fractions yielded by 1 cord of wood, 128 cu. ft.

	Charcoal in bushels	Wood alcohol in gallons	Calcium acetate in lbs.	Tar in gallons
Hard woods.....	40-50	8-12	150-200	8-20
Resinous woods..	25-40	2-4	50-100	30-60

In the case of resinous woods from 30 to 80 gallons of wood oil and turpentine oil are obtained before the charring temperature is reached.

Crude pyroligneous acid, sometimes called *pyroligneous vinegar*, or *wood vinegar*, is a dark brown liquid, having a strong smoky odor, and consists of acetic acid, diluted with more or less water, and holding in solution some creosote and empyreumatic oil, with methyl alcohol, methanol, and acetone. It is from this crude acid that the U. S. and British acetic acid, corresponding to the acetic acid of commerce, is usually obtained. The purification is effected as follows: The acid is saturated with milk of lime, whereby calcium acetate is formed in solution, and thus most of the tarry matter is precipitated. The solution of calcium acetate is then mixed with a concentrated solution of sodium sulphate, and, by double decomposition, sodium acetate is formed in solution, and calcium sulphate precipitated. The solution of sodium acetate is next subjected to evaporation, during which further impurities that separate on the surface are skimmed off. The solution, being duly concentrated, is set aside to crystallize, and the impure salt thus obtained, after having been partially purified by solution and recrystallization, is fused in an iron vessel, stirred until it dries, and, the heat being carefully raised, subjected to incipient carbonization, whereby remaining empyreumatic matters are carbonized, with little damage to the salt. The mass is then dissolved in water, and the solution, being strained and recrystallized, furnishes pure sodium acetate. Sometimes soda ash is used directly for the neutralization of the distillate instead of milk of lime. (See *Sodii Acetas.*) Finally, this salt, distilled with from 34 to 35 per cent. of its weight of sulphuric acid, yields the acetic acid of commerce, the residue being sodium sulphate, which is reserved for decomposing fresh portions of calcium acetate. The acid has still an empyreumatic flavor, which is removed by filtering it through animal charcoal or rectifying with potassium dichromate. The odor is due to furfurol, which, as Victor Meyer has shown, can be detected even in glacial acetic acid by the red coloration it gives with aniline. It may be removed from pyroligneous acid by agitating the liquid with 2 or 3 per cent. of benzene. The aqueous layer, after separation from the benzene, is stated to give, by a single distillation, a palatable table vinegar.

Acetic acid, according to E. R. Squibb, improves very much by age, and a sample examined for odor when freshly distilled would not be recognized as the same three months afterward.

An excellent quality of acetic acid was made by E. R. Squibb by an improvement on the process of Schwartz, the principal feature being the careful regulation of the heat, whereby the excessive charring of the wood is prevented and the formation of the tarry substances so reduced as to leave the acetic acid almost entirely free from empyreuma. The retorts, which are rectangular in shape, are supported by wheels secured to shafts, rotating in bearings connected with the sides, and are run upon car tracks into the ovens, after they have been loaded with some billets of oak wood from the transfer car, in an ingenious and simple manner. In the construction of the ovens, care is taken to economize the fuel and to secure control of the temperature by the use of corrugated bottoms to the retorts and dampers in the flues; when necessary, the vapors are condensed in earthenware air condensers. Experience has shown that the production and liberation of acetic acid take place at a considerably lower temperature than that sufficient to convert the wood into charcoal, Squibb having proved that wood begins to char at 218.3° C.; indeed, the wood which is removed from the retorts after the operation is over is sold as kindling wood, and has the color of black walnut. The crude acetic acid does not require the tedious method of purification usually employed, but is treated with soda ash, forming sodium acetate, which is decomposed by sulphuric acid, and the acetic acid recovered in a purified condition by distillation.

A higher yield of acetic acid may be obtained in the distillation of hard woods by the use of a small amount of phosphoric acid which acts as a catalyzing agent. Almost three times the normal yield of acid has been reported and an increase of from 40 to 90 per cent. in the yield of wood alcohol.

It has also been discovered that if wood tar from former distillations be placed in the still with fresh wood, in starting a new distillation, the methoxy groups in the tar split off yielding an additional amount of wood alcohol. (*J. Ind. Chem.*, 1918, p. 264.)

Experiments with hard woods seasoned for different periods showed that beech and maple give the best wood alcohol yields when wet, but the best results are obtained from birch when dry. (*J. I. and E. C.*, 1918, 262.)

Cocoanut shells and native woods are being employed in Ceylon for destructive distillation for the production of acetic acid. (*C. D.*, 1918, p. 82.)

During the World War the facilities of the wood distillation industry were found to be entirely inadequate to supply the demand for acetic acid and it was made from molasses which had been fermented into alcohol. The conversion of the molasses alcohol into acetic acid was accomplished by the quick fermentation process by passing the weak alcohol through percolators filled with beech wood shavings which had been inoculated with *Mycoderma Aceti.* Another method for the rapid production of acetic acid during the World War, was by converting acetylene into acetaldehyde which is then readily oxidized into acetic acid. (*Chem. Met. Eng.*, 1918, 397.)

The sp. gr. of the different acetic acids increases with their strength up to the density of 1.0681 at $\frac{25°C.}{25°C.}$ (maximum), after which it decreases until it reaches 1.0471 at $\frac{25°C.}{25.C.}$, the density of the strongest acid (*glacial acid*). The specific gravities of the glacial (100 per cent.) and the 39 per cent. acid are practically the same, and this applies also to the 74 and 81 per cent.; the 76, 77, and 78 per cent. acids have exactly the same density, the variations between 71 and 83 per cent. being very slight. It will thus be seen that specific gravity cannot be relied upon as a criterion for strength. The glacial acid may, however, be distinguished from the 39 per cent. acid by adding 10 per cent. of water, when, if the density increases, the specimen is the stronger acid.

For U. S. Pharmacopœia tables of specific gravity of various strengths of acetic acid, see Part III.

Description and Physical Properties.—" A clear, colorless liquid, having a strong, characteristic odor, and a sharply acid taste. Acetic Acid is miscible with water, alcohol, and glycerin. Specific gravity: about 1.045 at 25° C.

" Preserve in glass-stoppered bottles." *U. S.*

" Acetic Acid is strongly acid to litmus paper and responds to the reactions for acetates.

" Evaporate 20 cc. of Acetic Acid on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.002 Gm. Mix 5 cc. of the Acid with 10 cc. of ammonia T.S., add 5 cc. of silver nitrate T.S., and boil the solution for one minute: the color of the solution is not changed (*formic or sulphurous acid*). Dilute 4 cc. of the Acid in a glass-stoppered bottle with 20 cc. of distilled water, and add 0.5 cc. of tenth-normal potassium permanganate: the pink color is not changed to brown at once, and the liquid does not become entirely brown or free from a pink tint in less than one-half minute (*empyreumatic substances*). Separate portions of 1 cc. each of Acetic Acid diluted with 10 volumes of distilled water show no turbidity on the addition of 5 drops of barium chloride T.S. (*sulphate*), and no opalescence with 5 drops of silver nitrate T.S. (*Chloride*). Acetic Acid diluted with 20 volumes of distilled water meets the requirements of the test for *heavy metals*.

" **Assay.**—Proceed as directed under the assay for acids, using about 6 cc. of the Acid, accurately weighed, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$.

The British Pharmacopœia requires that acetic acid shall be " a clear, colorless liquid with pungent odor, yielding, when neutralised with an alkali, the *reactions* characteristic of acetates. Specific gravity 1.044. Yields no residue on evaporation, and no characteristic *reactions* for copper, chlorides, nitrates, sulphates, or sulphites. Does not immediately darken in color when exactly neutralised with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 5 millilitres require for neutralisation 28.7 millilitres of *N/1 solution of sodium hydroxide*. 2 millilitres do not completely decolorize a mixture of one drop of *solution of potassium permanganate* and 10 millilitres of *water* within half a minute (limit of empyreumatic matter). When tested for lead according to the quantitative method described in Appendix V, using 10 grammes in each Nessler glass, no difference in color is observed on the addition of the *solution of sodium sulphide* to one of the solutions (absence of lead). *Arsenic limit* 2 parts per million." *Br.*

Of the British acid (sp. gr. 1.044) the strength in hydrogen acetate is 33 per cent. The U. S. official acid is somewhat stronger than the British. In the arts *Acetic Acid No. 8* (sp. gr. 1.049) has long been used; it derives its name from the fact that one part added to sufficient water to make eight parts, by measure, constitutes so-called distilled vinegar, used in pickling; the latter is not equal to the official diluted acetic acid in strength (one-fifth weaker).

Charles F. Squibb has made numerous experiments proving the value of many strengths of acetic acid as menstrua for exhausting the valuable organic principles of drugs by percolation; he found even diluted acetic acid a reliable menstruum. J. P. Remington preferred a 10 per cent. acetic acid, and suggested a class of preparations termed *"acetracts"* to replace solid extracts. Acetic acid is a powerful solvent and can frequently be made to take the place of the more expensive alcoholic menstrua. (*A. J. P.*, 1897, p. 121.)

ACIDUM ACETICUM DILUTUM. *U. S., Br. Diluted Acetic Acid.*—

"Acetic Acid, 165 Gm.; Distilled Water, 835 Gm.; to make 1000 Gm. Mix them.

"Acetic Acid, 152.6 grammes; Distilled Water, sufficient to produce 1000.0 millilitres. Mix." *Br.*

"**Description and Physical Properties.**—A clear, colorless liquid, having a characteristic odor. Diluted Acetic Acid is miscible with water and with alcohol. Specific gravity: about 1.008 at 25° C.

"Preserve in glass-stoppered bottles." *U. S.*

"Diluted Acetic Acid is acid to litmus paper and responds to the reactions for acetates. It conforms to the tests for purity under *Acidum Aceticum,* allowance being made for the difference in strength.

"**Assay.**—Proceed as directed under the assay for acids, using about 25 cc. of the Acid, accurately weighed, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06004 Gm. of $CH_3.COOH$.

"Specific gravity 1.007. 20 millilitres require for neutralisation 16.7 millilitres of *N/1 solution of sodium hydroxide.* Free from the impurities indicated under 'Acidum Aceticum.'" *Br.*

Uses. *Crude Pyroligneous Acid.*—This acid having been incidentally described as the source of the acetic acid of commerce, it may be proper in this place to notice its uses. It is an active disinfectant and stimulant, the former property being mainly due to the presence of creosote. It has been used as a local application to *gangrene* and ill-conditioned *ulcers.* Kolipinski recommends it internally in doses of one to two teaspoonfuls (3.75–7.5 cc.) three times a day in the treatment of *arthritis deformans.* (*Trans. American Therap. Soc.,* 1907.) It has also been suggested for the preservation of food-stuffs, especially meat and fish. Its use, however, is specifically prohibited by the food laws of most states because of the presence of methyl alcohol which is absorbed by the food and particularly because of the fact that foods treated by immersion in pyroligneous acid rather than by "smoking" do not shrink in weight as do the latter (often 15 or 20 per cent.) and are therefore of less food value although they usually sell for the same price.

Glacial Acetic Acid.—Glacial acetic acid has been employed externally as a vesicant and as a caustic. For the former purpose it may be applied by means of a blotting paper moistened with the acid. It requires, however, considerable carefulness in its use and is generally inferior to cantharides. As an escharotic it is useful for the destruction of *warts* and *corns,* but has been largely replaced by the trichloracetic acid (see *Acidum Trichloraceticum*).

Strong acetic acid is also a useful agent for detecting small quantities of albumin and is used in the examination of urine, especially in conjunction with potassium ferrocyanide.

Diluted Acetic Acid.—The object of making diluted acetic acid official is to make available a weak solution of *pure* acetic acid which may be substituted for "distilled" vinegar in all formulas in which accuracy is required. For a long period diluted acetic acid has been made by mixing one part of acetic acid with seven parts of water by measure. *Acetic acid No. 8* is the commercial designation of an acid of 30 per cent. strength. The official diluted acid was made considerably stronger in the U. S. P., 1880, and the strength has not been altered in the subsequent revisions. "Distilled" vinegar is not vinegar made by distillation as is popularly supposed. The designation is applied to vinegar made by the beech-wood shaving or quick fermentation process from a weak alcoholic liquid which has been produced by distillation. Such a product contains a little organic matter, which is always darkened or precipitated when its acid is saturated with an alkali, a change which does not take place when diluted acetic acid is employed.

Either in the form of the official diluted acetic acid or in the form of natural or "distilled" vinegar, acetic acid is useful as a refrigerant drink in febrile conditions. As it is entirely oxidized in the system, escaping through the breath as carbonic acid, it does not tend to increase the acidity of the urine. It is also of service as an astringent and styptic. As an emergency remedy it may prove life-saving in *hemorrhage* from the stomach or uterus. For the former condition the diluted acetic acid should be further weakened by the addition of one or two parts of water, and this mixture taken in doses of a tablespoonful every few minutes. Owing to its volatility and pungency the vapor of acetic acid is frequently applied to the nostrils as an excitant in *syncope* or *headache* as a substitute for smelling salts. Used in this manner it has been recommended for the purpose of quieting post-anesthetic *nausea.*

Acetic acid is incompatible with carbonates, free chlorine, and ferric salts, the latter producing a deep red color which is destroyed by excess of mineral acids.

Dose, of diluted acetic acid, twenty to sixty minims (1.3–3.9 cc.).

Off. Prep.—From *Acetic Acid,* Acidum Aceticum Dilutum, *U. S.;* Acetum Aromaticum, *N. F.;* Linimentum Terebinthinæ Aceticum, *N. F.* From *Glacial Acetic Acid,* Linimentum Terebinthinæ Aceticum, *Br.*

ACIDUM ACETYLSALICYLICUM. U. S., Br.

ACETYLSALICYLIC ACID

"Acetylsalicylic Acid contains not less than 99.5 per cent. of $C_6H_4.O(CH_3CO)COOH$ 1:2." *U. S.*

"Acetylsalicylic Acid, $C_9H_8O_4$, may be obtained by the action of acetic anhydride or of acetyl chloride on salicylic acid." *Br.*

Aspirinum; Aspirin; Acide Acetylsalicylique, *Fr. Cod.;* Acidum Acetylo-salicylicum, *P. G.*

The name aspirin, by which this substance is popularly known, is not purely fanciful nor arbitrary. It is derived from the fact that salicylic acid as originally obtained from *Spiræa ulmaria* was at first known as *acidum spiricum.* Acetylsalicylic acid is made by heating together 50 parts of salicylic acid and 75 parts of acetic acid anhydride at about 150° C. It is said that this method does not give results and that no trustworthy method has ever been published for its preparation.

Another method suggested is by the acetylation of salicylic acid with acetyl chloride using one molecule of the former to 2½ molecules of the latter, keeping the reaction below 70°.

Aspirin cannot be purified by crystallization from water or solvents containing it on account of its tendency to undergo hydrolysis. It may be crystallized from benzene, methyl acetate, chloroform, or strong ethyl or methyl alcohol. It is then purified by recrystallization.

Description and Physical Properties.—"Small, colorless crystals or needles, or a white, crystalline powder. It is odorless, and in dry air is stable, but in contact with moisture it gradually decomposes into salicylic and acetic acids. One Gm. of Acetylsalicylic Acid is soluble in about 300 cc. of water, 5 cc. of alcohol, 17 cc. of chloroform, and in from 10 to 15 cc. of ether, at 25° C. It is less soluble in absolute ether. It is also soluble with decomposition in solutions of alkali hydroxides and carbonates.

"Preserve in well-closed containers." *U. S.*

"The melting point of Acetylsalicylic Acid, when determined in a bath previously heated to 120° C., is not below 132° C. When the Acid is heated with water for several minutes, then cooled and a drop or two of ferric chloride T.S. added, a violet-red color is produced. Boil about 0.5 Gm. of Acetylsalicylic Acid with 10 cc. of sodium hydroxide T.S. for a few minutes, cool, and add 10 cc. of diluted sulphuric acid: a white precipitate of salicylic acid is produced, and the odor of acetic acid is perceptible. Filter, add to the filtrate 3 cc. of alcohol and 3 cc. of sulphuric acid, and warm: the odor of ethyl acetate becomes noticeable.

"Ash: not more than 0.05 per cent. A solution of 0.5 Gm. of Acetylsalicylic Acid in 10 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). A solution of 0.5 Gm. of the Acid in 10 cc. of warm sodium carbonate T.S. is clear. Shake 1 Gm. of Acetylsalicylic Acid with 20 cc. of distilled water and 1 cc. of nitric acid for one minute, and filter: five cc. portions of the filtrate yield no opalescence or turbidity at once on the addition of a few drops of silver nitrate T.S. (*chloride*) or barium chloride T.S. (*sulphate*). Warm 1 Gm. of Acetylsalicylic Acid with 10 cc. of distilled water and 1 cc. of hydrochloric acid for two minutes, dilute with 40 cc. of distilled water, cool, and filter: the filtrate meets the requirements of the test for *heavy metals.* Dissolve 1 Gm. of Acetylsalicylic Acid in 5 cc. of alcohol, and allow the solution to evaporate spontaneously in a dish protected from dust: a white crystalline residue is obtained (*coloring matter, resinous substances*). Dissolve 0.1 Gm. of Acetylsalicylic Acid in 1 cc. of alcohol, dilute the solution with 48 cc. of cold distilled water, and add at once 1 cc. of a freshly prepared diluted ferric ammonium sulphate solution (made by adding 1 cc. of normal hydrochloric acid to 2 cc. of ferric ammonium sulphate T.S. and diluting with water to 100 cc.): the coloration, if any, produced in one-half minute, is not greater than that produced in a control test, using 1 cc. of a solution containing 0.1 Gm. of salicylic acid and 1 cc. of glacial acetic acid in 1 liter of water (*free salicylic acid*).

"**Assay.**—Add 50 cc. of half-normal sodium hydroxide to about 1.5 Gm. of Acetylsalicylic Acid, previously dried for three hours over sulphuric acid and accurately weighed, and boil gently for ten minutes. Titrate the excess of sodium hydroxide with half-normal sulphuric acid, using three drops of phenolphthalein T.S. as indicator. Make a blank test, using 50 cc. of half-normal sodium hydroxide, and from the comparisons make any necessary corrections. Each cc. of half-normal sodium hydroxide corresponds to 0.04503 Gm. of $C_6H_4.O(CH_3CO).COOH$.

The British Pharmacopœia described acetylsalicylic acid as follows: "A white, crystalline powder; taste slightly acid. Sparingly soluble in *water;* soluble in 5 parts of *alcohol* (90 per cent.); soluble in *ether.* Melting point from

133° to 135° C. When 0.5 gramme is boiled for two or three minutes with 10 millilitres of *solution of sodium hydroxide* and to the cooled solution excess of *diluted sulphuric acid* is added, a crystalline precipitate is produced which, after washing and drying, responds to the tests described under 'Acidum Salicylicum,' and the filtrate, after neutralisation, yields the *reactions* characteristic of acetates. When 0.5 gramme is shaken with 20 millilitres of *water* and 1 drop of *T. Sol. of ferric chloride* is added, no violet coloration is produced (absence of salicylic acid). *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. No appreciable ash." *Br.*

Many discrepancies have been noted with regard to the melting point of aspirin, some authorities claiming it to be 131° to 132° C., while others claim 134° to 135° C. The rate of heating seems to have considerable effect upon this factor.

Acetylsalicylic acid has been one of the most popularly used drugs of the last two decades. It has been known under many names such as: *xaxa, coxpyria, helicon, atonin, acetosal, regipyrin, asposal, empirin, nupyrin, salcetin, salacetol, anglopirin* and *salaspin.* It has been grossly and variously adulterated, especially abroad, during the World War. Among the adulterants reported have been, sugar, starch, talc, tartaric acid, acetanilid, phenacetin, milk sugar, salol, acid calcium phosphate, bone acid and cream of tartar.

Uses.—Although it has been shown that salicylic acid occurs in the urine within from twenty minutes to half an hour after the ingestion of acetylsalicylic acid, there is strong reason to believe that the drug circulates in the blood in large part unbroken; in other words, the action is not purely that of salicylic acid but there is also a different effect of acetylsalicylic acid. Christone and Lapresa (*P. J.*, lxxxv) have found that it requires forty minutes for the decomposition of acetylsalicylic acid by the gastric juice and that its toxicity is three times as great as that of sodium salicylate. Hanzlik and Presho (*J. P. Ex. T.*, 1923, xxi, 246) recovered from the urine undecomposed acetylsalicylic acid amounting to about 25 per cent. of the ingested dose. Moreover, there have been reported a very considerable number of cases of acetylsalicylic acid poisoning in human beings with symptoms very different from those caused by the salicylates and in many of these cases of poisoning the dosage has been so small as to practically exclude salicylic acid poisoning; in a case reported by Graham (*J. A. M. A.*, 1911), after two doses of five grains each there occurred marked cardiac weakness with pulse rate of 136 and edematous swelling of the face and mucous membranes with eversion of the lids and lips from the swelling; Shelby (*J. A. M. A.*, 1918, lxxi, 1381) has reported alarming edema of the face and throat from a single dose of 5 grains. In the third place, clinical experience has demonstrated that the range of therapeutic usefulness of acetylsalicylic acid is not the same as that of the salicylates.

Acetylsalicylic acid has been used in medicine (1) as an antirheumatic, (2) as an analgesic, (3) as an antipyretic, (4) locally.

In *inflammatory rheumatism,* it is generally of less value than ammonium or sodium salicylate. On the other hand, in those *myalgias* or *neuralgias* of dubious origin commonly diagnosed as *chronic rheumatism,* acetylsalicylic acid is often of great usefulness. In a general way it may be said that the more nearly these types of pain approach to true rheumatism the more likely it is that sodium salicylate will be a superior drug to acetylsalicylic acid. As an analgesic acetylsalicylic acid comes in competition with acetanilid and other coal tars for the relief of *headaches, neuritis,* and similar painful conditions. As an antipyretic, as has been shown by Chambers (*B. M. J.*, 1912), Bondi (*Th. M.*, 1911, p. 179) and others, it far exceeds the salicylates in power. It has been used for the reduction of the temperature in *typhoid fever* and *rheumatic fever* but in some cases it is liable to produce serious collapse. Locally it has been recommended by Fetterolf (*T. G.*, November, 1908) in *acute tonsillitis* and has also been employed to a lesser extent in *eczema* and other *skin diseases.*

Overdoses of acetylsalicylic acid commonly produce ringing in the ears as do the inorganic salicylates. Frequently, however, even in quantities not excessive it produces a very different type of intoxication. Among the most common symptoms are profuse sweating, cold extremities, either with or without a fall in body temperature, rapid or irregular pulse and occasionally albuminuria. In many reported cases there has been marked facial edema involving not only the skin but the mucous membrane of the mouth and throat.

Cooke (*J. A. M. A.*, Sept. 6, 1919) reports a group of a familial idiosyncrasy to acetylsalicylic acid. In these patients there was urticaria and violent bronchial asthma.

Acetylsalicylic acid readily undergoes hydrolysis with aqueous solvents with the liberation of free salicylic and acetic acids. In pure water complete decomposition takes place in 100 days. Acids hasten the rapidity of such change. In the presence of moisture acetylsalicylic acid unites with various bases to form salts (acetylsalicylates), with many organic substances it forms liquid entectic mixtures, when triturated.

The statement that quinine and acetylsalicylic acid react upon each other to form the poisonous quinotoxin has been contradicted by the experiments of Sollmann. Ruddiman and Lanwermeyer (*J. A. Ph. A.*, 1924, xiii, p. 1009; *J. A. M. A.*, 1921, April 9) experimented with mixtures of acetyl salicylic acid with basic quinine and also the sulphate, bisulphate, hydrochloride and other cinchona alkaloids. They found that the mixture with quinine alkaloid, after several months, changed to a brownish red viscid mass if exposed to the light, but when kept in the dark the change was less rapid; this mixture tested on frogs was not more poisonous than the freshly made mixture nor than the equivalent dose of acetyl salicylic acid. It has of course the characteristic color incompatibilities of the salicylates.

The *dose* of acetylsalicylic acid is from five to fifteen grains (0.3–1.0 Gm.).

ACIDUM ACETYLTANNICUM. U. S.

ACETYLTANNIC ACID

Acid. Acetyltan. **[Diacetyltannic Acid, Tannyl Acetate, Acetannin.]**

"Acetyltannic Acid is a product obtained by the acetylization of tannic acid." *U. S.*

Tannigen.

Acetannin is prepared by heating tannin with acetic anhydride in the presence of glacial acetic acid; after the reaction is completed the product is poured into water and the resultant precipitate washed and dried.

Leech (*J. A. M. A.*, 1920, lxxv, 1123) has shown that the commercial samples of acetannin differ greatly among themselves. The proportion dissolved by water varied from six to eighteen per cent. of the sample tested. The amount dissolved by 1 per cent. solution of sodium bicarbonate ranged from 30 to 90 per cent. of the sample. Their solubility in artificial gastric juice was slightly less than in plain water.

Description and Physical Properties.—"A yellowish-white, or a grayish-white powder which darkens on exposure to light. It is odorless or has a slight acetous odor. Acetyltannic Acid is only slightly soluble in water and in alcohol, but is soluble in ethyl acetate. It is soluble with gradual decomposition in aqueous solutions of alkali hydroxides and carbonates. It is also soluble in aqueous solutions of sodium borate and of sodium phosphate.

"Warm 0.2 Gm. of Acetyltannic Acid with 2 cc. of alcohol and 2 cc. of sulphuric acid: the odor of ethyl acetate is noticeable. A solution of Acetyltannic Acid in sodium phosphate T.S. (1 in 100) after standing for several hours precipitates albumin solution, but this property is destroyed by the presence of an excess of alkali. When dissolved in an aqueous solution of sodium borate (1 in 25), it does not precipitate albumin.

"Ash: not more than 0.3 per cent. Dry about 1 Gm. of Acetyltannic Acid, accurately weighed, for three hours at 100° C.: the loss does not exceed 3 per cent. Shake 1 Gm. of Acetyltannic Acid with 50 cc. of distilled water during five minutes and filter: a 25 cc. portion of the filtrate requires for neutralization not more than 1.2 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*). To the remainder of the filtrate add 2 drops of ferric chloride T.S.: a green but not a blue color is produced (*free tannic acid*). Digest 1 Gm. of Acetyltannic Acid with a solution of 2 Gm. of sodium bicarbonate in 200 cc. of distilled water for three hours at about 40° C., filter through a counterbalanced filter or a Gooch crucible, wash the insoluble residue with 4 portions of distilled water, 10 cc. each, and dry to constant weight at 110° C. The weight of the residue does not exceed 0.15 Gm. Digest 1 Gm. of Acetyltannic Acid with 200 cc. of distilled water for two hours, shaking at frequent intervals. Filter through a dry filter into a dry flask, rejecting the first 20 cc. of the filtrate, evaporate 100 cc. of the subsequent filtrate to dryness on a water bath and dry the residue for three hours at 100° C. The weight of the residue does not exceed 0.03 Gm. (*soluble substances*).

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—Acetyl tannin has a very mild astringent effect due to the presence of a small amount of free tannic acid. In alkaline solutions it is slowly hydrolized, liberating its combined tannic acid to exercise the characteristic astringent effect. According to Sollmann (*J. P. Ex. T.*, 1921, xvii, 87) this decomposition takes place rather slowly, the astringency reaching its maximum in about two hours. This would mean that the drug would exercise very little astringent effect in the stomach or duodenum; that in the lower part of the intestinal canal it would exert a mild continuing effect as it was gradually hydrolized. Acetannin is used exclusively in the treatment of *diarrheas* of various types, such as chronic *enteritis, cholera infantum, dysentery,* etc. It has even been asserted to have a beneficial effect in relieving symptoms of *intestinal tuberculosis.*

The *dose* is five to fifteen grains (0.3 to 1 Gm.).

ACIDUM BENZOICUM. U. S., Br.

BENZOIC ACID **Acid. Benz.**

"Benzoic Acid, dried at 100° C. for two hours, contains not less than 99.3 per cent. of $C_6H_5.COOH$." *U. S.*

"Benzoic Acid, $HC_7H_5O_2$, may be obtained from benzoin, or prepared synthetically." *Br.*

Acidum Benzoicum Sublimatum, Flores Benzoes; Flowers of Benzoin; Flowers of Benjamin; Acide benzoïque; Fleurs de Benjoin, *Fr.;* Acidum Benzoïcum, *P. G.;* Benzoesäure, Benzoeblümen, *G.;* Acido benzoico, *It., Sp.*

Although most of the benzoic acid on the market is manufactured synthetically the older method of preparing it from benzoin is still used commercially to some extent despite the much higher price of the product. The acid made from the natural resin is distinguished commercially as "English benzoic acid" while the synthetic product is designated as "German benzoic acid." The latter term was formerly applied to a product made from hippuric acid of the urine of cattle; this does not appear, however, to be any longer an article of commerce. During the World War the suggestion was made to revive this process and it was estimated that one pound of benzoic acid could be produced from the daily urine of 15 cows. This yield would hardly be profitable and as far as we know was not actually practised.

The acid which exists in benzoin combined with resin may be volatilized by heat and collected in a condenser. Formerly the benzoin was mixed with sand before sublimation; but this is now usually omitted as not only useless but probably injurious by favoring the production of empyreumatic substances. Unless the temperature be very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid, and gives it a brown color, from which it cannot be entirely freed by bibulous paper; and this result, even with the greatest caution, sometimes takes place. Mohr, after experimenting, recommended the following plan as unobjectionable: In a round cast iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the vessel is closed by a sheet of filter paper or some fabric as muslin or cheese cloth through which the vapors may pass but which prevents the sublimed material from falling back into the exhausted resin. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand bath and continued for three or four hours. The vapors pass through the porous diaphragm, which absorbs the empyreumatic oil, and are condensed within the upper chamber in brilliant white crystals, having an agreeable odor of benzoin. (*Ann. Pharm.*, xxix, 178.) The heat must be kept below 120° C. during the operation. Strips of paper passed at irregular intervals across the cap prevent the falling back of crystals. The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the benzoin with lime or sodium carbonate. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin* or *flowers of Benjamin.*

Another mode of separating the acid from benzoin is by combining it with a salifiable base and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with calcium hydroxide and water, filtering the solution of calcium benzoate thus obtained, and precipitating the benzoic acid with hydrochloric acid. The crude benzoic acid is then purified by sublimation.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the benzoin is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by sodium carbonate dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off and the sodium benzoate contained in the residual liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which deposits the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19.425 per cent. By the process of Scheele he obtained 13.5 per cent.; by the agency of sodium carbonate, 12 per cent.; by sublimation, only 7.6 per cent. Scharling prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*A. J. P.*, xxiv, 236.)

The acid is manufactured very cheaply by several synthetic methods. The processes most commonly employed start with *toluene*, $C_6H_5CH_3$. In the first method the toluene is changed to benzotrichloride, $C_6H_5CCl_3$, by passing chlorine into rectified toluene heated to 110°, and contained in an earthenware or lead lined vessel, until the product possesses a specific gravity of 1.35. Iron and moisture must be carefully excluded during this stage of the operation. The benzotrichloride is then heated with milk of lime with a trace of powdered iron added as a catalyzer. Benzaldehyde is produced to some extent and is recovered by distillation. The calcium benzoate which is produced is then decomposed with hydrochloric acid and the crude benzoic acid purified by sublimation or by recrystallization from water.

In the second method the benzoic acid is obtained as a by-product in making benzaldehyde from toluene (see *Benzaldehydum*); in the process of manufacturing much of the benzaldehyde is converted into benzyl alcohol and calcium benzoate by the excess of lime used. This latter salt is then treated with hydrochloric acid, and the benzoic acid thus set free after which it is purified as previously described. In a third method the toluene is only chlorinated to the point where benzylchloride is formed. The benzylchloride is then heated in an apparatus provided with a reflux condenser with lime or caustic soda and some calcium hypochlorite is gradually added. The resulting calcium benzoate is purified as in the previous processes. The synthetic acid is frequently resublimed in contact with benzoin, in order to give it the vanilla-like odor of the acid sublimed from the gum. A method of making benzoic acid from tannin or gallic acid is described in *Ph. Era*, 1892, 172. P. Schulze produced benzoic acid by heating benzyl chloride or benzotrichloride in the presence of ferric benzoate or metallic iron. The process is patented. (*Ph. Centralh.*, 1896, 221.)

Owing to the scarcity in the market of benzoin yielding paying quantities of benzoic acid, it was asserted that the English manufacturers used certain varieties of Botany Bay gum (see *Gum acroides*, Part II), and obtained a larger yield of an acid which was at one time regarded as cinnamic, but has been shown to be benzoic acid. (*N. R.*, Feb., 1879.) Benzoic acid is also found as a decomposition product of benzaldehyde or of oil of bitter almond in the bottom of containers of these substances which have been exposed for some time.

Description and Physical Properties.—"Lustrous scales or friable needles. The synthetic Acid is white and odorless, or it may have a slight odor of benzaldehyde. The natural Acid is white or yellowish, acquiring a darker color on exposure to light, and has a slight odor of benzoin. Benzoic Acid is somewhat volatile at moderately warm temperatures, and freely volatile with steam. One Gm. of Benzoic Acid is soluble in 275 cc. of water, 2.3 cc. of alcohol, 4.5 cc. of chloroform, 3 cc. of ether, 10 cc. of benzene, 30 cc. of carbon disulphide or carbon tetrachloride, and in 23 cc. of oil of turpentine, at 25° C. One Gm. is soluble in 18 cc. of boiling water, and in 1.5 cc. of boiling alcohol. It is soluble in fixed or volatile oils and is sparingly soluble in petroleum benzin.

"Benzoic Acid melts between 120° and 122° C. Benzoic Acid responds to the reactions for benzoates.

"Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of the synthetic Acid in 2 cc. of sulphuric acid does not become darker than light yellow when warmed for five minutes at 50° C. The color produced by the Acid from benzoin tested in the same manner does not become darker than light brown (*readily carbonizable substances*). Dissolve 0.3 Gm. of the Acid in 15 cc. of hot water, and add to the solution 2 cc. of tenth-normal potassium permanganate: the odor of benzaldehyde is not perceptible (*cinnamic acid*). Mix 0.5 Gm. of Benzoic Acid and 0.7 Gm. of calcium carbonate with a little distilled water in a crucible, dry the mixture, and incinerate it at a low red heat. Dissolve the residue in 20 cc. of diluted nitric acid, filter, wash the filter and insoluble residue with 15 cc. of distilled water, add to the filtrate 0.5 cc. of tenth-normal silver nitrate, and dilute with distilled water to 50 cc. Dissolve 0.7 Gm. of the same calcium carbonate in 20 cc. of diluted nitric acid; filter if necessary, add 0.5 cc. of tenth-normal silver nitrate, and dilute with distilled water to 50 cc. Add to this solution fiftieth-normal hydrochloric acid, drop by drop, mixing well after each addition, until the turbidity matches that in the test with the Benzoic Acid. If the synthetic Acid is tested, not more than 0.6 cc. of fiftieth-normal hydrochloric acid is required in the control test to match the turbidity, and, if the natural Acid is tested, not more than 0.3 cc. of fiftieth-normal hydrochloric acid is required (*chlorinated compounds*).

"Preserve in well-closed containers, in a cool place, protected from light.

"**Assay.**—Dry about 1 Gm. of Benzoic Acid at 100° C. for two hours, and dissolve 0.5 Gm. of the dried Acid, accurately weighed, in 25 cc. of diluted alcohol, which has previously been neutralized with tenth-normal sodium hydroxide, using three drops of phenolphthalein T.S. as indicator. Titrate this solution with tenth-normal barium hydroxide until the pink color is restored. From the number of cc. of tenth-normal barium hydroxide consumed, subtract one-fifth of the volume of fiftieth-normal hydrochloric acid used in the test for chlorinated compounds. Each cc. of tenth-normal barium hydroxide corresponds to 0.01221 Gm. of $C_6H_5.COOH$." *U. S.*

"Soluble in 450 parts of *water*, in 3 of *alcohol* (90 per cent.), in 2.5 of *ether*, and in 7 of *chloroform*. Melting point 121.5° C., but if sublimed from benzoin about 120° C. Heated in a dry test-tube it melts and sublimes leaving only a slight residue. Volatilises in the vapor of *water*. The solution obtained by gently warming 0.2 gramme with 20 millilitres of *water* and 1 millilitre of *N/1 solution of sodium hydroxide* and filtering yields a pale reddish precipitate with *T. Sol. of ferric chloride*. When 0.5 gramme is heated in a closed crucible with twice its weight of *calcium carbonate*, the mass dissolved in *diluted nitric acid*, and *solution of silver nitrate added*, not more than the slightest cloudiness results (absence of chlorobenzoic acid). Yields no characteristic *reactions* for oxalates. Does not develop the odor of benzaldehyde when warmed with its own weight of *potassium permanganate* and ten times its own weight of *diluted sulphuric acid* (absence of cinnamic acid). *Arsenic limit* 2 parts per million." *Br.*

It is entirely soluble in solutions of potassium, sodium, or ammonium hydroxides, from which it is precipitated by hydrochloric acid. On carefully neutralizing any of these solutions and adding solution of ferric sulphate previously diluted with water, a flesh-colored precipitate is produced.

Potassium permanganate has been depended upon more than any other reagent to distinguish between benzoic acids as obtained from different sources. Schacht proposes the following test: If 3 grains of benzoic acid be dissolved in 96 minims of solution of potassium hydroxide, sp. gr. 1.777, diluted with 96 minims of distilled water, and 10 drops of a solution made by dissolving 1 grain of potassium permanganate in 200 grains of water be added to it and the whole heated to boiling, dark green liquids (in which brown precipitates gradually appear) are produced if the benzoic acid be obtained from urine, from toluene, or from commercial benzoin, while if the benzoic acid be from Siam benzoin (sublimed or made by wet process) decoloration of the liquids and brown precipitates are produced, due to the presence of cinnamic acid. (*Ph. Centralh.*, 1881, 565.) The odor of bitter almonds confirms the presence of cinnamic acid. Essell (*Ph. Ztg.*, 1904, 272) modifies this test to secure greater accuracy as follows: 0.2 Gm. of the *finely* powdered benzoic acid and 5 cc. of tenth-normal permanganate solution are mixed in a test tube of wide diameter and securely corked. When the red color is discharged (usually after a few minutes) 5 cc. more of tenth-normal permanganate solution are added, and the tube is set aside from fifteen to thirty minutes, with frequent shaking. If then the cork be removed the odor of benzaldehyde will be strongly perceptible in the presence of 5 per cent. of cinnamic acid, and distinctly recognizable if only 1 per cent. is present. It is claimed that benzoic acid from benzoin can be distinguished from that from other sources by adding resorcinol and sulphuric acid to the alcoholic solution of the acid; the benzoin-benzoic acid gives a beautiful red color, due probably to a trace of vanillin or other aldehyde in the natural product. (Göldner, *Ph. Ztg.*, 1892, 697.)

The principal impurities to be looked for in the synthetic acid are the chlorinated compounds which contaminate the resulting end product. It is sometimes difficult to detect these chlorobenzoic acids and it is stated that the high assays sometimes recorded in the analysis of sodium benzoate are accounted for by their presence.

Benzoic acid is incompatible with salts of iron, silver, lead, and mercury. It precipitates a solution of quinine sulphate and is decomposed by hydrogen dioxide in the presence of inorganic acids with the production of salicylic acid.

Uses.—When benzoic acid is taken into the system it appears in the urine chiefly as hippuric acid. This conversion would appear to take place in the kidneys, since, after the exhibition of large doses, benzoic and not hippuric acid can be detected in the blood, while even small amounts of hippuric acid injected into the blood produce violent poisoning. Moreover, Bunge and Schmiedeberg have succeeded in converting benzoic acid into hippuric acid by passing blood containing benzoic acid slowly through the kidneys immediately after their removal from the body. In rare cases, according to Meissner and Shepard, the benzoic acid is converted into succinic instead of hippuric acid. When it is given very freely a portion of the benzoic acid escapes unchanged. Where the nitrogen necessary for the conversion of the benzoic into hippuric acid comes from, is at present unknown. *A priori* it would seem probable that the source of this nitrogen was the urea, but the testimony as to the effect of benzoic acid upon the urea and uric acid excretion is contradictory. The most recent investigations indicate that benzoic acid has practically no effect on the elimination of either urea or uric acid, although Denis (*J. P. Ex. T.*, 1915, vii, 601) finds that in large doses the output of uric acid is increased.

The only advantageous uses of benzoic acid as a remedy are connected with its antibacterial properties. As small quantities as one part in a thousand have a distinctly inhibiting action on the growth of many micro-organisms, and in somewhat stronger solution it is actively germicidal. It is a popular ingredient in many of the supposedly antiseptic mouth washes. It has also been used internally as a urinary antiseptic but because of its irritant action upon the stomach is much better administered for such purpose in the form of one of its salts. For a discussion of the use of benzoic acid as a food preservative, see *Sodii Benzoas.*

Dose, ten to thirty grains (0.65–2.0 Gm.).

ACIDUM BORICUM. U. S., Br.

BORIC ACID Acid. Bor. [Boracic Acid]

"Boric Acid, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent. of H_3BO_3." *U. S.* "Boric Acid may be obtained by the interaction of sulphuric acid and borax, and contains not less than 99.5 per cent. of orthoboric acid, H_3BO_3." *Br.*

Hydrogen Borate; Acidum Boracicum; Acidum Orthoboricum; Boracic Acid, Acide Borique Cristallisé, *Fr. Cod.;* Acidum Boricum Cristallisatum, *P. G.;* Borsäure, *G.;* Acido borico, *It., Sp.*

Boric acid occurs in small amount, most probably in combination as a magnesium salt, in sea water and in certain mineral waters, as the hot springs of Wiesbaden, Aix-la-Chapelle, and Vichy; in certain mineral substances, such as the *borocalcite* which occurs in considerable quantities in the niter beds of Chile; in the natural borax or *tincal,* first found in the basins of dried-up lagoons in Central Asia, and afterwards in large amount in Clear Lake, California; in *ulexite* (sodium and calcium borate) and *colemanite* (calcium borate). The last of these minerals yields by far the largest amount of the boric acid now obtained on the Pacific coast. It is found in a large vein deposit in San Bernardino County, California, where it is mined and shipped to the works of the Borax Consolidated Co. (Limited), at Alameda, California. (See *Sodii Boras.*)

Boric acid itself is extracted, under the name of *sassolin,* from the lagoons of the volcanic districts of Tuscany, and from the crater of Vulcano, one of the Lipari Islands. In the neighborhood of Monte Rotondo, Lago, Zolforeo, Sasso, and Larderello are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures, called *suffioni,* a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. It is still very dilute, containing only about 2 per cent. of boric acid. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it is sufficiently concentrated to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid thus obtained contains from 74 to 84 per cent. of boric acid, the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate.

Considerable amounts of a calcium borate known as *pandermite* are produced in Turkey, but the chief foreign producer at present is Cnile.

The native borax minerals of California supply, at present, the entire American demand for boric acid. Boric acid is obtained from borax by acidulating a hot saturated solution of borax with hydrochloric or sulphuric acid. Upon cooling the mixture, crystals of boric acid separate from the more soluble sodium chloride or sulphate. The crystals thus obtained may be purified by recrystallization from water and if a small amount of albuminous matter be added before crystallizing, large, light, shining crystalline scales of the acid may be obtained.

Description and Physical Properties.—"Transparent, colorless scales of a somewhat pearly luster, or six-sided, triclinic crystals, or a white, bulky powder, slightly unctuous to the touch. It is stable in the air. One Gm. of Boric Acid is soluble in 18 cc. of water, 18 cc. of alcohol, and in 4 cc. of glycerin, at 25° C. One Gm. is soluble in 4 cc. of boiling water and in 6 cc. of boiling alcohol. Heated to 100° C., Boric Acid loses water, forming metaboric acid (HBO_2), which slowly volatilizes at that temperature. Heated to about 160° C., Boric Acid fuses to a glassy mass of tetraboric or pyroboric acid ($H_2B_4O_7$). At about 185° C. the fused mass swells, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent non-volatile, hygroscopic mass. Boric Acid volatilizes from a boiling aqueous or alcoholic solution.

"An aqueous solution of Boric Acid (1 in 50) is slightly acid to litmus paper. Boric Acid responds to the reactions for borates.

"One Gm. of Boric Acid dissolves completely in 10 cc. of boiling alcohol (*insoluble substances*). An aqueous solution of Boric Acid meets the requirements of the test for *heavy metals.* An aqueous solution of Boric Acid meets the requirements of the test for *arsenic.*

"**Assay.**—Dry about 2.5 Gm. of Boric Acid to constant weight over sulphuric acid, weigh accurately, dissolve in 50 cc. of distilled water and 50 cc. of glycerin, and titrate with normal sodium hydroxide, phenolphthalein T.S. being used as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06192 Gm. of H_3BO_3." *U. S.*

"Soluble in 25 parts of *water,* in 4 of *glycerin,* and in 30 of *alcohol* (90 per cent.), the solutions being clear. *Turmeric paper* moistened with an aqueous solution slightly acidified with *hydrochloric acid* becomes brownish-red on gently drying, and this color changes to a greenish-black on the addition of *solution of potassium hydroxide.* The alcoholic solution burns with a flame tinged with green. 1 gramme dissolved in a mixture of 25 millilitres of *water* and 20 millilitres of *glycerin* requires for neutralisation not less than 16.0 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for copper, and not more than the slightest *reactions* for iron, calcium, magnesium, chlorides, or sulphates. *Lead limit* 25 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Boric acid has a sp. gr. of 1.434, dissolves in three parts of boiling water and in volatile oils, but is insoluble in ether. On evaporation of the alcoholic solution, the boric acid volatilizes even more readily than from the aqueous solution. Glycerin, when heated, dissolves a very large quantity of boric acid. (See *Glyceritum Boroglycerini,* Part I; also *Boroglyceride,* Part II.) Its aqueous solution tastes somewhat acid, colors litmus paper a wine red, and changes turmeric paper to a reddish color, analogous to that produced by alkalies, even when hydrochloric acid is present. On moistening the paper so reddened and then dried, with ammonia water or caustic alkali solution it turns first blue and then a dirty gray color. This reaction has been taken advantage of by Chamot and Cole in the development of a micro-chemical test for boric acid and borates. Fibers of viscose silk, cellulose xanthate, are dyed with turmeric solution. These sensitized fibers are then used in testing by placing one drop of a suspected solution, acidified with diluted hydrochloric acid solution, on a glass slide, add one of the turmeric stained fibers and apply gentle heat until the liquid has evaporated. If boric acid be present the fibers will have a rose tint which is changed to a deep blue by the application of a 1 per cent. solution of an alkali. This test will show 0.000025 mgm. of boric acid in 1 drop of solution. Cassol and Gerraus (*Chem. News,* 1903, 27) use curcumin with oxalic acid for determining the presence of boric acid when used as a preservative for foods.

Bori acid is a weak acid, or may even act as a base. Thus, with sulphuric and phosphoric acids it forms compounds which may be considered as salts. Its compounds with bases, when in solution, are readily decomposed by other acids, but at red heat boric acid will other acids, but at red heat boric oxide will displace many of the stronger but more volatile acids.

Boric acid requires 18 parts of cold water to dissolve it, and this fact has led to many attempts to increase its solubility without interfering with its usefulness. The use of glycerin has been officially sanctioned. Scholz and Mansier recommended the use of magnesium carbonate (11 per cent.), but such an addition is not always permissible. When equal parts of boric acid and borax are dissolved in boiling water a crystalline mass separates on cooling, which has been termed *boro-borax.* Its advantages are increased solubility and neutral reaction. Thus 12 parts of borax and 13 parts of boric acid will dissolve in 75 parts of water, making a solution containing the equivalent of 19 per cent. of boric acid. The tendency of the crystals of boric acid to slip from under the pestle renders the process of pulverization very tedious. It is essential that the acid be in an impalpable powder when it is desired to make an ointment. The gradual addition of ether to the acid has been suggested as a valuable aid to trituration. Manufacturers at the present time supply boric acid made by precipitation in an impalpable powder. The remarkable volatility of boric acid when in alcoholic solution has been observed by Schneider and the fact utilized in its quantitative determination. (*Zeit. Oest. Apoth. Ver.*, 1896, 791.)

Methyl alcohol gives better results than ethyl alcohol in the flame test for boric acid.

"**Assay.**—Dissolve about 2.5 Gm. of Boric Acid,

B. H. St. John noted an unsatisfactory end point in this titration and suggests the use of methyl red as an indicator with some slight change in manipulation details. (*A. J. P.*, 1917, p. 8.)

Uses.—Boric acid in single dose is about as near physiologically inert as a substance can be, indeed, the assertion has been made on reputable authority that, in the frog, at least, it is less poisonous than sodium chloride. In very large doses, however, it has some depressant action upon the spinal centers. When taken by the mouth it is absorbed, somewhat slowly but completely, and eliminated unchanged through the kidney. According to Rost (*A. I. P. T.*, xv, p. 291) it may be detected in the urine for some days after a single dose and when taken repeatedly tends to accumulate in the system.

Although it has been abundantly shown that boric acid has no germicidal effect, in concentrated solutions it is distinctly antiseptic. Because of freedom from toxic properties or local irritant influence its solution is widely used as a detergent wash in inflammations of mucous membranes, such as *rhinitis, conjunctivitis,* and *stomatitis.* It is also useful as an internal antiseptic in *fermentative cystitis.* It differs from most urinary antiseptics in that it is almost as efficacious in alkaline as in acid urine and has the further advantage that it tends to restore the acidity. Although its antibacterial properties are too feeble to make boric acid generally useful as a surgical disinfectant it appears to have considerable value as a local application, either in the form of the ointment or solution, in local infections. Ochsner (*Trans. Southern Surg. and Gynecol. Ass.*, 1916) believes that while it does not inhibit the growth of pathogenic bacteria it greatly reduces their virulence, and affirms that dressings of saturated solution of boric acid are almost specific in infections by *streptococcus* or *staphylococcus albus* or *pneumococcus.* So potent is its antagonism against the latter micro-organism that he has found it of value (*Illinois Med. Jour.*, June, 1917) as an internal remedy in various pneumococcus infections. He asserts that after the local application of wet dressings of saturated solution of boric acid there is considerable absorption of the drug, boric acid appearing within the urine within an hour. Internally it has from time to time been recommended in the treatment of *epilepsy* but is probably without value.

Boric acid and the borates have been used to a considerable extent as food preservatives and there has waged an acrimonious dispute as to their harmfulness when used for this purpose. Although as mentioned above their toxicity is very low, yet there have been reported a few cases in which death was apparently induced from washing out internal cavities with solutions of boric acid. These instances, however, are so rare and the dose of boron ingested probably so large as to have little bearing on the harmfulness of the boric acid food preservatives. A considerable number of cases of skin eruptions have been reported from the continued use of the boron derivatives over long periods of time. It must be acknowledged, however, that even in these cases the quantity ingested has been larger than would be at all probable from the use of any food containing it. The question of whether or not its use in smaller quantities over long periods of time is injurious can scarcely be considered as definitely settled, but in the elaborate investigation of the U. S. Department of Agriculture under H. A. Wiley, it was found that quantities of less than 0.5 Gm. daily, if continued over long periods of time, caused disturbances of digestion and assimilation (see also Lindet, *P. J.*, 1920, civ, 46). The question, however, is not merely whether it is theoretically possible for boric acid used in the preservation of food to have an injurious action upon the system, but whether the danger from this preservative is any greater than from other agents which are used for the same purpose. Certainly if it is possible to obtain undecomposed food free from preservatives they are preferable, but we do not believe that boric acid is any more injurious to the system than, for instance, is saltpeter.

For the detection of boric acid in food products, see *Chem. News,* 1903, 27; *A. Pharm.*, 1904, 194; *J. Am. C. S.*, 1904, 91.

The only important incompatibility of boric acid is the fact that in combination with salicylic acid it sometimes acts as an alkaloidal precipitant. A solution containing two and one-half grains of boric acid and one-fourth grain of salicylic acid to the fluidounce will precipitate quinine, strychnine, and other alkaloids.

Dose, of boric acid, five to twenty grains (0.3–1.2 Gm.).

ACIDUM BROMAURICUM. N. F.

BROMAURIC ACID Acid. Bromaur.

"It contains $HAuBr_4.5H_2O$ (607.97) corresponding to not less than 32 per cent. of gold, Au." *N. F.*

This is a compound of gold and bromine corresponding to chlorauric acid $HAuCl_4$. It may be considered as a combination of gold bromide and hydrobromic acid, $AuBr_3 + HBr$, crystallizing with 5 molecules of water of crystallization.

Bromauric acid is prepared by the action of *bromine* on metallic gold. *Auric bromide* is first produced, which is dissolved in hydrobromic acid and upon concentration the compound $HAuBr_4.5H_2O$ crystallizes out.

Description and Physical Properties.—"Bromauric Acid occurs as dark red-brown, flat, needle-shaped crystals, or as irregular, coarse, granular masses; odorless, and having a metallic and acid taste. Permanent in the air when pure; when chloride is present the salt is deliquescent. Bromauric Acid melts at about 27° C. It is very soluble in water and in alcohol. Its aqueous solution is strongly acid to litmus, and yields with silver nitrate T.S. a yellowish white precipitate, insoluble in nitric acid and but slightly soluble in ammonia water.

"Ignite 0.1 Gm. of Bromauric Acid, heat the resulting residue of gold with 5 cc. of nitric acid, add 15 cc. of distilled water and filter; no weighable residue remains on evaporating the filtrate and igniting. Dissolve 0.2 Gm. of Bromauric Acid in 10 cc. of distilled water, add 16 cc. of tenth-normal silver nitrate V.S. and 12 cc. of ammonium carbonate T.S., digest the mixture for ten minutes on a water-bath, then cool and filter. The filtrate, on supersaturating with nitric acid, does not become more than slightly opalescent (*chloride*). Bromauric Acid is decomposed on exposure to red heat and leaves a residue of metallic gold equivalent to not less than 32 per cent. of the weight taken.

"Preserve it in glass-stoppered, amber-colored bottles." *N. F.*

Uses.—This preparation is in the National Formulary only because it is an ingredient in the so-called *gold and arsenic bromide* (see *Liquor Auri et Arseni Bromidi,* Part III). This combination is similar to a proprietary solution that at one time enjoyed a considerable popularity as a remedy for *diabetes.* That this solution is of any greater value in this condition than other arsenicals is open to question.

Dose, of bromauric acid, one-twentieth to one-eighth of a grain (0.003–0.008 Gm.).

Off. Prep.—Liquor auri et arseni bromidum, *N. F.*

ACIDUM CITRICUM. U. S., Br.

CITRIC ACID Acid. Cit.

"Citric Acid contains not less than 99.5 per cent. of $C_3H_4(OH)(COOH)_3.H_2O$." *U. S.* "Citric Acid may be obtained from the juice of the fruit of various species of Citrus, and contains not less than 99.5 per cent. of hydrogen citrate, $H_3C_6H_5O_7,H_2O$." *Br.*

Acidum Citri, s. Limonis, s. Limonum, s. Limonorum; Acide citrique, *Fr. Cod.;* Acide du Citron, *Fr.;* Acidum citricum, *P. G.;* Citronensäure, Citronsäure, *G.;* Acido citrico, *It., Sp.*

Citric acid is the peculiar acid to which lemons and other citrus fruits owe their sourness. It is present also as one of the constituent organic acids in the juice of other fruits, such as the cranberry, the red whortleberry, the berry of the bittersweet, the red gooseberry, the currant, the strawberry, the raspberry, the tamarind, and the red elderberry (fruit of *Sambucus pubens* Michx.). The latter berry contains citric acid so abundantly that it has been proposed as a source of the acid by Thibierge, of Versailles. It is contained also largely in the fruit of *Cyphomandra Hartwegi* Sendt., a solanaceous plant, indigenous in Mexico, Peru, and other parts of South America, where it is called *tomato de la paz.* Citric acid is now known to be a normal constituent of fresh, whole cows' milk; the amount present is about 0.19 Gm. per 100 cc., and it may be estimated by a method given in *Arch. Chem. Micros.,* 1915, viii, 120. It also occurs in the shoots and leaves of grape vine, tobacco, and as a calcium salt in the beet, willow, etc. The commercial source of citric acid is lime, lemon, and bergamot juice; large quantities of *lime juice* are made in Sicily, concentrated, and exported to England and the United States. Citric acid, which was formerly imported in large quantities from Great Britain, is now made extensively in the United States, especially in California. Culls and damaged oranges and lemons afford a source for raw material that promises soon to supply the entire need of the country.

The acid is extracted from lemon or lime juice by a very simple process, for which we are indebted to Scheele; it is one requiring some careful manipulation.

On the large scale the juice is placed in a wooden vat, closed at top, and is saturated with whiting (calcium carbonate.) Carbonic acid gas is thus evolved, which passes out by an exit pipe, and may be used in the manufacture of sodium bicarbonate, while calcium citrate precipitates. The supernatant liquor, containing much extractive matter, is drawn off, and the calcium citrate is decomposed by diluted sulphuric acid, liberating the citric acid, and precipitating the lime as a sulphate. The mixture of citric acid and calcium sulphate is run off into a wooden filter-rack, lined with lead, furnished with a perforated false bottom, and lined throughout with stout twilled flannel. The solution of citric acid passes off through a pipe leading from the bottom of the back to suitable reservoirs.

The sulphate is washed until it becomes tasteless, and the washings are run off into the same reservoirs. The filtered acid solution is then concentrated by evaporation in wooden vessels lined with lead, through which steam is made to pass by means of coiled lead pipes. As citric acid is liable to decomposition if subjected to a very high temperature, the use of the vacuum pan is highly advantageous in concentrating the solution. When the liquor is sufficiently concentrated, it is transferred to cylindrical sheet-lead vessels, placed in a warm situation, to crystallize. The crystals at first obtained are colored. In order to purify them, they are redissolved in a small quantity of water, with the assistance of heat, and the solution is digested with purified animal charcoal, filtered, evaporated, and the crystals, after having been washed and drained, are dried on wooden trays lined with sheet-lead, in a room heated by steam. It is desirable to have a slight excess of sulphuric acid, as this rather favors than otherwise the crystallization of the citric acid. It is found necessary, also, to add occasionally a small proportion of sulphuric acid to the citric acid liquor, during the progress of its concentration. From 8000 lemons are obtained 600 liters of juice containing from 4.5 to 6 per cent. of citric acid. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of having undergone the acetous fermentation.

Processes for producing citric acid by fermentation of carbohydrates have been patented in Germany. The earlier of these (1893) involved species of citromyces (*Citromyces pfefferienus* and *C. glaber*). Later (1897) it was discovered that the same result may be obtained by means of *Mucor pyroformis*. The latter fungus is found on decomposing fruit, especially on pears and apples; its spore carriers grow only in a moist atmosphere and form long white filaments, terminated by brownish-black heads. It can be readily obtained in pure culture by sowing the spores in a suitable medium, such as sugar solutions, beer wort, steamed rice, starch paste, etc., the ordinary room temperature being favorable for its growth. The solution becomes acid from the formation of citric acid. (*J. Soc. Chem. Ind.*, June 30, 1897; see also *P. J.*, 1894, 893; 1902, 551; *A. J. P.*, 1916, p. 337.)

Ohley (*Ph. Era*, 1901, 706) has devised a process which consists in diluting fresh concentrated lemon juice with twice its volume of water, filtering after standing over night to remove albumen, then adding a calculated quantity of calcium chloride, followed by solution of sodium hydroxide, gradually added, until the solution is exactly neutral, when, upon stirring, a magma of calcium citrate is quickly deposited. From this the sodium chloride formed is readily removed by hot water, and the calcium citrate is then decomposed by the calculated quantity of sulphuric acid. The main advantages of this process are: convenience, a yield approximating to theoretical figures, and decidedly superior purity of product. In the manufacture of citric acid, the quantity of alkaline salt added to the juice must be sufficient to combine with all of the citric acid, and the amount of sulphuric acid added should thoroughly decompose the calcium citrate and not be in excess, to avoid contaminating the crystals with sulphuric acid.

Synthetic citric acid may be prepared by the action of hydrocyanic acid upon acetone-dicarboxylic acid and subsequent hydrolysis of the product, but the process is not economical.

Description and Physical Properties.—" Colorless, translucent crystals, or a white powder. It is odorless, has an acid taste, and is efflorescent in warm air. One Gm. of Citric Acid is soluble in 0.5 cc. of water, 1.8 cc. of alcohol, and in about 30 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water.

" An aqueous solution of Citric Acid is acid to litmus paper and responds to the reactions for citrates. When slowly ignited, Citric Acid is gradually decomposed without emitting an odor resembling that of burning sugar (*difference from tartaric acid*).

" Ash: not more than 0.05 per cent. Neutralize 10 cc. of an aqueous solution of the Acid (1 in 10) with ammonia T.S., add 5 drops of diluted hydrochloric acid, cool, and add 2 cc. of calcium chloride T.S.: no turbidity is produced (*oxalic acid*). The addition of 1 cc. of barium chloride T.S. to 10 cc. of an aqueous solution of the Acid (1 in 100), to which 3 drops of hydrochloric acid have previously been added, causes no turbidity (*sulphate*). Mix 1 Gm. of powdered Citric Acid with 10 cc. of sulphuric acid in a test tube previously rinsed with sulphuric acid, and maintain the temperature of the mixture at 90° C. for one hour: no color darker than yellow develops (*tartaric acid*). Ten cc. of an aqueous solution of the Acid (1 in 50) mixed with 0.5 cc. of hydrochloric acid meets the requirements of the test for *heavy metals*, page 439. Dissolve 10 Gm. of Citric Acid in 20 cc. of distilled water, add 2 cc. of sulphurous acid T.S., and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the solution possesses a slight odor of ammonia. Cool, transfer the solution to a 50 cc. graduated cylinder, dilute with sufficient distilled water to measure 50 cc., and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not darker than the color of a control solution prepared as follows: dissolve 2 Gm. of reagent ammonium chloride in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S., and stronger ammonia water, as directed above; transfer the mixture to another 50 cc. cylinder, dilute it with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia. The two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*)." *U. S.*

"Soluble in about 0.5 part of *water*, somewhat less soluble in *alcohol* (90 per cent.), and slightly soluble in *ether*. Yields, when neutralised, the *reactions* characteristic of citrates. 1 gramme dissolved in *water* requires for neutralisation 14.2 millilitres of *N/1 solution of sodium hydroxide*. Yields no characteristic *reactions* for copper or iron, and not more than very slight *reactions* for calcium or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 1.4 parts per million. 1 gramme of powdered Citric Acid mixed with 10 millilitres of *sulphuric acid* in a test-tube previously rinsed with *sulphuric acid* acquires not more than a pale yellow color when kept at a temperature of 90° C. for one hour (absence of tartaric acid). Ash not more than 0.05 per cent." *Br.*

Assay.—"Proceed as directed under the assay for acids, using about 3 Gm. of Citric Acid and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.07004 Gm. of $C_3H_4(OH)(COOH)_3.H_2O$." *U. S.*

It is nearly insoluble in chloroform, benzene and petroleum benzin. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition.

Sometimes crystals of tartaric acid are substituted for or mixed with the citric, or the two acids may be mixed in powder, a fraud which is detected by adding a solution of potassium acetate to that of the suspected acids, when, if tartaric acid be present, a crystalline precipitate of potassium bitartrate will be formed.

Another method of detecting tartaric acid is to digest the suspected acid with ferric hydroxide in a test tube, afterwards to raise the heat slowly to the boiling point, and, having allowed the excess of hydroxide to subside, to decant the clear liquid, and evaporate it to a syrupy consistence. If the acid be pure, the liquid remains limpid, and of a fine red color; if contaminated with tartaric acid, even to the extent of only one per cent., it becomes cloudy, and deposits tartrate. Another test is potassium permanganate, of which an alkaline solution is without action on citric acid, while under the influence of tartaric acid the manganese peroxide is deposited. Still another method takes advantage of the fact that when citric acid is oxidized with potassium permanganate in an acetic acid solution acetone is formed which can readily be detected qualitatively or estimated quantitatively. Tartaric acid does not undergo this decomposition but malic acid does and must be separated from the citric acid by taking advantage of the differences in the barium salts. The tartaric acid also may be removed by converting in the usual way into the comparatively insoluble acid potassium tartrate (*Pharm. Weekblad.*, 1917, p. 686.)

Lead is often found in the metallic state in citric acid in small quantity, and this arises from small portions being detached in breaking off the crystals from the crystallizing vats. The presence of lead or copper may be detected as above, or by igniting in a porcelain crucible a small quantity of the acid, dissolving the ash in a few drops of nitric acid, diluting largely, and passing hydrogen sulphide through it, a black precipitate indicating the impurity. A most delicate test for lead is that of the U. S. P. given above. Some interesting observations in relation to the presence of lead in citric acid and citrates are recorded by Haussmann in *A. J. P.*, 1894, 173.

The formula of the anhydrous acid is $C_6H_5O_7H_3$. It is a tribasic acid, and may therefore yield three classes of citrates according as one, two, or three atoms of hydrogen are replaced by metal, the first two classes being acid citrates, and the third class neutral citrates. When crystallized from its solution by cooling, it contains one molecule of water. Crystals of the formula $(C_6H_8O_7)_2 + H_2O$ have also been formed. (Flückiger, *Pharm. Chem.*, 1879, p. 157.) Witter (*Ph. Centralh.*, 1892, 1003) has obtained anhydrous citric acid, in crystals melting at 153° C., by heating aqueous solutions of the hydrated acid to 130° C. If citric acid be further heated after all its water of crystallization has been driven off, there will be produced *aconitic acid* ($H_3C_6H_3O_6$), which is found naturally in aconite, larkspur, black hellebore, equisetum, yarrow, and other plants. For method of preparation of aconitic acid see *U. S. D.*, 20th ed., p. 28.

Uses.—Except for its local irritant action citric acid is almost without effect upon the system. In any ordinary quantity it is entirely oxidized in the body and eliminated through the lungs as carbonic acid. For this reason the citrates of sodium and potassium, although neutral salts in themselves, tend to alkalize the system, appearing in the urine as carbonates. This change probably occurs in nearly all the tissues of the body so that after the ingestion of a citrate, carbonates can be found in the blood. According to Bence Jones, however, when sufficiently large quantities are given some of the citric acid appears in the urine unchanged.

Citric acid, is mildly astringent and is popularly used to a large extent in various inflamed conditions of the skin, such as *sunburn.* It is, however, inferior in this regard to acetic acid. Although it has been suggested as a substitute for lemon juice in *scurvy,* it is entirely without value as it contains no vitamine.

A substitute for lemonade may be made by dissolving from two to four parts of the acid, mixed with sugar and a little oil of lemon, in nine hundred parts of water; or twenty grains of the acid may be dissolved in a pint of water, and sweetened with sugar which has been rubbed on fresh lemon-peel. Citric acid is used as one of the ingredients in the effervescent salts on account of the presence of the water of crystallization which is an essential factor in the process. In the experiments of Strong, one-half to one per cent. of citric acid was found to be so poisonous to the cholera germ as to make impure water to which it was added probably a safe drink. It was further found that a large Philippine lemon, containing 40 cc. of juice, was the equivalent of 2.74 grammes of citric acid. (*Report Government Laboratories, Philippine Islands,* Sept. 1, 1903.)

Citric acid is incompatible with alkali hydroxides and carbonates, converting them into citrates, in the latter case with effervescence; with calcium and strontium salts citric acid and its compounds produce white precipitates of the insoluble citrates of these respective elements.

It possesses the valuable property of lessening or entirely preventing the coloration incompatibility of iron salts with tannin.

Dose, of the acid, from five to thirty grains (0.32–2.0 Gm.).

Off. Prep.—Syrupus Acidi Citrici, *U. S.;* Syrupus Aurantii, *U. S.*

ACIDUM FORMICUM. N. F.

FORMIC ACID Acid Formic.

“An aqueous solution containing not less than 24 per cent. of and not more than 26 per cent. of HCOOH (46.02).” *N. F.*

Aminic Acid; Hydrogen Carboxylic Acid; Ameisensaure, *G.;* Acide Formique, *Fr.*

This acid, although deriving its name from having first been obtained from the ant (*Formica rufa*), is remarkable for the number of sources of its production. It can be made from some species of caterpillars, from the blood or urine, of human beings; it is found in the products of decomposition of a number of vegetable substances, in common oil of turpentine, as a decomposition product of tartaric acid contained in various fruits and in the juice of the stinging nettle. It may be produced artifically in many ways: by the oxidation of methyl alcohol, the saponification of chloroform, and the hydrolysis of hydrocyanic acid; the following process yields good results: 50 Gm. of glycerine and 50 Gm. of crystallized oxalic acid are placed in a suitable retort attached to a condenser and the mixture carefully heated until the temperature rises to 105° C., it is then allowed to cool to about 50° C. and 50 Gm. more of oxalic acid are added and the mixture heated very slowly to 115° C. The condensed liquid may be drawn off and another addition of oxalic acid made and the distillation continued almost indefinitely. When oxalic acid and glycerin are distilled together, chemical reaction occurs, glyceryl formate being produced; this is saponified by the water which is separated, formic acid distils over and glycerin is reproduced.

The pure formic acid occurs as a colorless liquid with a pungent odor, a boiling point of about 100.8° C., is soluble in all proportions in water, alcohol, ether or glycerin. Its specific gravity is about 1.22.

The 25 per cent. solution of formic acid which is official in the National Formulary is described as follows:

Description and Physical Properties.—“Formic Acid is a clear colorless liquid, having a strongly acid reaction and a characteristic pungent odor. Specific gravity about 1.058 at 25° C. It is miscible with water or alcohol. A white precipitate of mercurous chloride is formed on warming formic acid with mercuric chloride T.S.

“When Formic Acid is diluted with five times its volume of distilled water, separate portions yield no precipitate or turbidity on the addition of silver nitrate T.S. after adding nitric acid (*chloride*); or of barium chloride T.S. (*sulphate*); or of calcium chloride T.S. after supersaturating with ammonia water. Formic acid is volatilized on heating and evaporating 20 cc. to dryness on a water bath, not more than 0.002 Gm. of a residue remains (*oxalic acid*). Formic Acid when supersaturated with solution of sodium hydroxide develops no pungent or empyreumatic odor (*acrolein, allyl formate*). Heat 1 cc. of Formic Acid on a water bath with 1.5 Gm. of yellow mercuric oxide and 10 cc. of distilled water for ten minutes shaking frequently and filter the liquid; the filtrate does not show an acid reaction (*acetic acid*). Add 1 drop of tenth-normal Iodine to 10 cc. of Formic Acid; the iodine color is not destroyed (*sulphurous acid*). Formic Acid does not respond to the test for heavy metals.

“**Assay.**—Pour about 5 cc. of Formic Acid into a weighing bottle, stopper, weigh accurately, dilute with about 50 cc. of distilled water and titrate with normal potassium hydroxide using phenolphthalein T.S. as indicator. Each cc. of normal potassium hydroxide corresponds to 0.04602 Gm. of HCOOH.” *N. F.*

An aqueous solution of formic acid, usually the crude or unrefined product containing from 15 to 20 per cent. of the acid, is used in the textile industries under the name of *scroop liquid.* Certain fabrics, when rinsed in this solution, acquire the crisp, punging sound characteristic of silk when squeezed or twisted, which is known in the industries as scroop.

Uses.—Pure formic acid is an active caustic. In diluted condition it is locally irritant and astringent. It is used to a considerable extent on the European continent as a counter-irritant in strengths of from 5 to 10 per cent. Formic acid has also been recommended for its astringent effect, especially for the purpose of lessening excessive *sweating of the feet.* It has been used in the same manner as smelling salts in the treatment of *fainting spells,* its effects in this condition being due to local irritant effect of the vapors on the nasal mucosa.

An old folk lore that bee sting was beneficial in *rheumatism* has led to the use of formic acid and its salts in the treatment of this condition but there is no sufficient evidence of their value. Fleig (*A. G. M.,* 1905) could obtain no physiological basis for the use of the formates except as stimulants to the gastric mucous membrane and to the kidney. It has been employed as a diuretic either alone or in combination with theobromine. It has been employed by Stern and others (*J. A. M. A.,* 1906) internally for the treatment of inoperable *cancers, diphtheria* and *tuberculosis.* Berret (*K. T. W.,* 1906) reports good results from sodium formate in the treatment of muscular *tremors* such as *paralysis agitans* and senile or toxic tremors.

The *dose* of the N. F. solution of formic acid is from two to five minims (0.12 to 0.3 cc.).

Off. Prep.—Spiritus acidi formici. *N. F.*

ACIDUM HYDRIODICUM DILUTUM
U. S., Br.

DILUTED HYDRIODIC ACID Acid. Hydriod. Dil.

"Diluted Hydriodic Acid is an aqueous solution containing not less than 9.5 per cent. and not more than 10.5 per cent. of HI." *U. S.*

"Diluted hydriodic Acid is an aqueous liquid containing, when freshly prepared, 10 per cent. by weight of hydrogen iodide, HI, and 1 per cent. by weight of hydrogen hypophosphite, HPH_2O_2. It may be obtained by the action of hydrogen sulphide on a solution of iodine, with the subsequent addition of hydrogen hypophosphite." *Br.*

Acide hydroidique dilué, *Fr.;* Verdünnte Jodwasserstoffsäure, *G.*

Hydriodic acid was discovered by Clement and Desormes in 1813. The strong aqueous solutions, from 49° to 60° Baumé, are used in organic chemistry as reducing agents. The stronger acids are prepared by the reaction of phosphorus and iodine to produce phosphoric and hydriodic acids, the latter being separated from the former by distillation.

The weaker solution (ten per cent.) only is used in pharmacy and medicine. Several methods for making this have been suggested. The old process consisted in passing hydrogen sulphide into a bottle containing iodine and water until the iodine disappeared and the liquid was colorless, it was then filtered to separate the precipitated sulphur and the filtrate heated to drive off the excess of hydrogen sulphide. H. Kolbe (*J. Pr. Chem.,* 1879, 172, and *A. J. P.,* June, 1877) adds phosphorus to iodine in a retort filled with carbon dioxide. Heat is applied, and water added; on application of moderate heat, hydriodic acid gas free from iodine is produced. C. Winckler (*A. J. P.,* May, 1880) dissolves iodine in carbon disulphide, adds sufficient water to form a layer on top of the solution of iodine, and passes a stream of hydrogen sulphide through the mixture; when this has acquired a yellow color, the layers are separated, the aqueous hydriodic acid is boiled a few minutes to expel hydrogen sulphide, and it is then supposed to be chemically pure.

Neither the U. S. nor the Br. at present give any formula for the preparation of this acid. That of the U. S. IX was as follows: "Potassium Iodide, *one hundred and thirty-five grammes;* Potassium Hypophosphite, *ten grammes;* Tartaric Acid, *one hundred and thirty-six and five-tenths grammes;* Distilled Water, Diluted Alcohol, each, *a sufficient quantity,* to make *one thousand grammes.*

"Dissolve the Potassium Salts in *two hundred and fifty mils* of Distilled Water with the aid of heat, and the Tartaric Acid in *four hundred mils* of Diluted Alcohol. Having poured the solution of Tartaric Acid into a bottle of about one thousand mils capacity, add the solution of the Potassium Salts and shake the mixture briskly. Cool the mixture to about 5° C. for several hours and, having inserted a pledget of purified cotton tightly in the throat of a funnel, transfer the contents, of the bottle to the funnel. When all the liquid has passed through, wash the bottle and crystalline precipitate with Diluted Alcohol in successive small portions until the *filtrate* weighs *one thousand grammes.* Evaporate the liquid at a moderate temperature, on a water-bath, until all of the Alcohol has evaporated, and add sufficient Distilled Water to make the product weigh *one thousand grammes.*" *U. S. IX.* The hypophosphite is added in order to provide a small quantity of hypophosphorous acid which acts as a preservative, while the diluted alcohol aids in the precipitation of the potassium bitartrate because of the insolubility of the latter in alcohol. The cooling of the mixture is also used to assist in the separation of the potassium bitartrate.

$$KI + 2H_2C_4H_4O_6 + KPH_2O_2 = HI + 2KHC_4H_4O_6 + HPH_2O_2$$

Description and Physical Properties.—"A colorless or not more than pale yellow, odorless liquid. Specific gravity: about 1.100 at 25° C.

"It is strongly acid to litmus paper. Diluted Hydriodic Acid responds to the reactions for iodides.

"A 5 cc. portion of Diluted Hydriodic Acid, when evaporated to dryness on a water bath and ignited at dull red heat (about 750° C.), leaves not more than 0.165 Gm. of residue. No blue color is produced on adding a few drops of starch T.S. to 5 cc. of the Acid (*free iodine*). The addition of 1 cc. of potassium sulphate T.S. to 10 cc. of the Acid causes no turbidity (*barium*). Mix 0.5 cc. of Diluted Hydriodic Acid with 10 cc. of distilled water, add 8 cc. of silver nitrate T.S. and 6 cc. of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, cool, and filter: the filtrate upon supersaturation with nitric acid shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid. A 10 cc. portion of Diluted Hydriodic Acid shows no more *sulphate* than corresponds to 1.0 cc. of fiftieth-normal sulphuric acid. A 10 cc. portion of Diluted Hydriodic Acid without further acidulation meets the requirements of the test for *heavy metals*. Mix 5 cc. of Diluted Hydriodic Acid with 1 cc. of nitric acid, and evaporate the liquid to dryness on a water bath: the residue meets the requirements of the test for *arsenic*.

"Preserve in amber-colored, glass-stoppered bottles, protected from light. Do not dispense if it contains free iodine.

"**Assay.**—Pour about 5 cc. of Diluted Hydriodic Acid into a tared flask, weigh accurately, dilute with 20 cc. of distilled water, add 50 cc. of tenth-normal silver nitrate, and shake the mixture well. Then add 5 cc. of nitric acid, heat the mixture on a water bath until the precipitate has a bright yellow color, cool, add 2 cc. of ferric ammonium sulphate T.S., and determine the residual silver nitrate by titration with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.01279 Gm. of HI." *U. S.*

"A clear, colorless liquid. Yields, when neutralized, the *reactions* characteristic of iodides. Yields no characteristic *reactions* for barium, calcium, potassium, sulphates, or sulphides. When to 5 grammes of the Acid, diluted with a little *water,* 45 millilitres of *N/10 solution of silver nitrate,* 5 millilitres of nitric acid, and 0.5 millilitre of *solution of ferric sulphate* are added, not less than 5 or more than 7 millilitres of *N/10 solution of ammonium thiocyanate* are required to produce a permanent pink coloration. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Diluted hydriodic acid is incompatible with oxidizing agents in general, such as chlorates, nitrates, permanganates, hydrogen dioxide, etc., which liberate iodine. It is also incompatible with salts of mercury, bismuth, and cupric and ferric salts.

Uses.—Diluted hydriodic acid was introduced into use as a medicine by Andrew Buchanan, of Glasgow. There can be little doubt that hydriodic acid is capable of producing the alterative effects of iodine, and it may be given in all cases to which that medicine is applicable. When the solution becomes discolored it may be irritant through the liberated iodine, and should not be dispensed. It need not be thrown away, however, as exposure to strong sunlight for several days will usually effect a reduction of the iodine and the restoration of its original colorless condition.

Dose, ten minims (0.6 cc.) three times a day, well diluted.

Off. Prep.—Syrupus Acidi Hydriodici, *U. S.; Br.*

ACIDUM HYDROBROMICUM DILUTUM. Br.

DILUTED HYDROBROMIC ACID

"Diluted Hydrobromic Acid is an aqueous liquid containing 10 per cent. by weight of hydrogen bromide, HBr. It may be obtained by the interaction of bromine and sulphurous acid, and subsequent distillation." *Br.*

Acidum Bromhydricum Dilutum, Acidum Bromohydricum Solutum, *Fr. Cod.;* Acide Bromhydrique dissous, Acide hydrobromique dilué, *Fr.;* Acidum hydrobromicum, *P. G.;* Verdünnte Hydrobromsäure, Bromwasserstoffsäure, *G.*

Hydrobromic acid was discovered by Balard in 1830. The strong acid (48 to 50 per cent.) is used in organic chemistry both in manufacturing and for analytical purposes.

The weaker acid (10 per cent.) only is used in pharmacy and medicine. It was official in the U. S. IX, but was dismissed at the last revision.

Dr. E. R. Squibb published a process (*A. J. P.*, 1878, 116) for making this acid which was based on the decomposition of potassium bromide with sulphuric acid. (See *U. S. D.*, 19th ed., p. 32.) A more convenient process is that of Dewitt C. Wade (*Peninsular Medical Journal,* Feb., 1875), modelled after Buchanan's method of making hydriodic acid, which directs that 120 grains of potassium bromide be dissolved in one fluidounce of water, and 153 grains of tartaric acid be added to the solution; acid potassium tartrate is produced, the greater part of which crystallizes out on standing twelve hours at a low temperature, and a solution of hydrobromic acid is formed, sp. gr. 1.228, containing about 80 grains pure hydrobromic acid to the fluidounce, equivalent to nearly 15 per cent. Fothergill's method although based upon Wade's formula, yields a weaker acid. Diluted hydrobromic acid made in this way is open to the objection of containing cream of tartar, and probably some undecomposed potassium bromide in solution, and thus is not strictly pure. To lessen this, Charles Rice proposed the addition of a double quantity of alcohol to facilitate the precipitation, recovering the alcohol by distillation subsequently. (*N. R.*, 1877, p. 107.) Other processes have been suggested for the preparation of hydrobromic acid.

Edward Goebel (*N. R.*, Sept., 1880) proposed a method based on Glover's process, which is to decompose 148 grains of barium bromide dissolved in half an ounce of water, with 50.6 grains of sulphuric acid, diluted with two drachms of distilled water; the precipitated barium sulphate is washed with distilled water until the filtrate weighs 810 grains to make the 10 per cent. acid solution. Markoe (*Proc. A. Ph. A.*, 1875, p. 686) recommends an economical process, based upon the reaction which takes place between phosphorus and bromine producing hydrobromic and phosphoric acids, the former being subsequently separated by distillation. A convenient method for obtaining a small amount of hydrobromic acid gas or solution was described by L. H. Friedburg, in a communication before the New York Section of the American Chemical Society (May, 1905). Bromine is allowed to trickle into paraffin which is kept in a melted condition by placing the flask containing it in a shallow steam bath. A portion of the bromine reacts with the hydrocarbon to form hydrobromic acid. The vapors from this reaction are carried to a second flask containing paraffin, joined to the first flask and standing with it in the steam bath, which absorbs part of the free bromine. (See also Gassman's process, *S. W. P.*, 1893, 107.) Marshall proposed a method which depends on the easy solubility of bromine in hydrobromic acid, the conversion of the bromine into sulphur bromide by the addition of sulphur, and the ready decomposition of sulphur bromide when shaken with water.

Properties.—Hydrobromic Acid is of a pungent and irritating odor, and fuming on contact with the atmosphere when concentrated, but in its diluted state it is odorless. On adding chlorine or nitric acid to diluted hydrobromic acid, there is liberated bromine, which is soluble in chloroform or carbon disulphide, imparting to these liquids a red or yellow color. On distilling it, weak acid passes over first; when the temperature of 126° C. is reached, an acid of 48 per cent. remains, which may be distilled unchanged.

Diluted hydrobromine acid is officially described as follows:

"Yields, when neutralised, the *reactions* characteristic of bromides. Specific gravity 1.077. 10 millilitres require for neutralisation 13.3 millilitres of *N/1 solution of sodium hydroxide*. 2 millilitres require for complete precipitation 26.6 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for barium, chlorides, phosphates, or sulphites, and only a slight *reaction* for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.01 per cent. of residue on evaporation." *Br.*

The U. S. IX gave the following additional tests:

"Silver nitrate T.S. produces a yellowish-white precipitate, which is insoluble in diluted nitric acid, slowly soluble in an excess of stronger ammonia water, but readily soluble in a 10 per cent. solution of sodium thiosulphate. Evaporate 25 cc. of Diluted Hydrobromic Acid from a platinum or porcelain dish and afterwards dry it at 110° C.; not more than 0.0025 Gm. of residue remains. The addition of 1 cc. of barium chloride T.S. to 10 cc. of the Acid produces not more than a slight cloudiness (*sulphuric acid*); the addition of 1 cc. of potassium sulphate T.S. to 10 cc. of the Acid causes no turbidity (*barium*). Shake 10 cc. of the Acid with 2 cc. of chloroform; no color is imparted to the latter (*free bromine*). Now add 5 drops of ferric chloride T.S. and shake the mixture; the chloroform does not acquire a violet tint (*iodine*). Ten cc. of Diluted Hydrobromic Acid, without further acidulation, does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 5 cc. of Diluted Hydrobromic Acid with 1 cc. of nitric acid and evaporate the liquid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1). Mix 0.5 cc. of Diluted Hydrobromic Acid with 10 cc. of distilled water, add 8 cc. of silver nitrate T.S., and 6 cc. of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, cool and filter. The filtrate, on supersaturating with nitric acid, does not at once become more than slightly turbid (*chloride*).

"**Assay.**—Pour about 20 mils of Diluted Hydrobromic Acid into a tared flask, weigh accurately, dilute with 30 mils of distilled water, and titrate the liquid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of HBr.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.08093 Gm. of HBr. Each gramme of Diluted Hydrobromic Acid corresponds to not less than 1.17 mils nor more than 1.30 mils of normal potassium hydroxide V. S." *U. S. IX.*

Concentrated hydrobromic acid has been furnished by manufacturing chemists containing from 20 to 50 per cent. of absolute hydrobromic acid; C .T. Tyrer states that the stronger acids are prone to show discoloration in a few days after being made, but that even the highly colored acids, when diluted to the official strength, become colorless; the concentrated acid attacks glass rapidly and the silica is not thrown out on dilution; he recommends acid of the sp. gr. 1.250 as having the most suitable limit of concentration for pharmaceutical purposes. (*Y. B. P.*, 1896, 296.)

The following table by Biel will be found useful in showing from the specific gravities of solutions the percentage of absolute hydrobromic acid.

Biel's Table of Percentage and Specific Gravity of Hydrobromic Acid

Per cent. HBr.	Specific gravity at 15° C.	Per cent. HBr.	Specific gravity at 15° C.
1	1.0082	26	1.219
2	1.0155	27	1.229
3	1.0230	28	1.239
4	1.0305	29	1.249
5	1.038	30	1.260
6	1.046	31	1.270
7	1.053	32	1.281
8	1.061	33	1.292
9	1.069	34	1.303
10	1.077	35	1.314
11	1.085	36	1.326
12	1.093	37	1.338
13	1.102	38	1.350
14	1.110	39	1.362

Uses.—The action of hydrobromic acid upon the system is practically identical with that of the alkaline bromides, (see *Potassii Bromidum.*) but the acid is too irritant to the stomach to be used freely. Two fluidrachms contain about 12 grains of bromine, equivalent to 18 grains of potassium bromide, and may be given at once, well diluted with water or syrup. The addition of a trace of oil of lemon to the mixture will impart a flavor to this dose closely similar to lemonade.

Diluted Hydrobromic Acid is incompatible with many oxidizing agents, as is hydriodic acid; it is also incompatible with salts of lead, silver, mercury, and bismuth.

Dose, from one-half to two fluidrachms (1.8 to 7.5 cc.).

Off. Prep.—Elixir Calcii Bromidi. *N. F.*

ACIDUM HYDROCHLORICUM. U. S., Br.

HYDROCHLORIC ACID. Acid. Hydrochl.

"Hydrochloric Acid is an aqueous solution containing not less than 31 per cent. and not more than 33 per cent. of HCl." *U. S.* "Hydrochloric Acid is a liquid containing 31.79 per cent. by weight of hydrogen chloride, HCl, and 68.21 per cent. by weight of water. It may be obtained by dissolving in water the gas produced by the interaction of sulphuric acid and sodium chloride." *Br.*

Acidum Muriaticum, *U. S.*, 1870; Acidum Hydrochloratum, Spirit of Sea Salt, Marine Acid, Muriatic Acid, Chlorhydric Acid· Acidum Chlorhydricum, *Fr. Cod.;* Acide chlorhydrique, Acide muriatique, *Fr.;* Acidum hydrochloricum, *P. G.;* Salzäure, Chlorwasserstoffsäure, *G.;* Acido cloridrico concentrato, Acido muriatico, *It.;* Acido clorhidrico, Acido muriatico, *Sp.*

Preparation.—Hydrochloric acid was originally described by Valentine in the 15th century. He obtained it by distilling sodium chloride and ferrous sulphate together and called it *spirit of salt.* Glauber, in the 17th century prepared it by the method by which it is yet mainly obtained, *i.e.*—by the action of sulphuric acid on sodium chloride or common salt. In England it is produced in enormous quantities during the decomposition of common salt for the purpose of making sodium sulphate, from which soda ash and sodium carbonate are afterwards manufactured in immense quantities. The decomposition of the sea salt is performed in semi-cylindrical vessels, the curved part, next the fire, being made of iron, and the upper or flat surface, of stone. The acid gas is conveyed by a pipe to a double-necked stoneware receiver, half filled with water, and connected with a row of similar receivers, likewise containing water. As carried out on a larger scale, the decomposition of the salt takes place in hemispherical iron pans, 9 feet in diameter, covered by a brick-work dome; upon the mass of salt the requisite quantity of sulphuric acid is allowed to run from a leaden cistern placed above the decomposing pan. Volumes of hydrochloric acid gas are evolved, which collect in the space between the pan and the brick-work dome, whence they pass by a brick-work or earthenware flue into upright towers or condensers. These towers are filled with bricks or coke, down which a small stream of water is allowed to trickle. The gas, passing upward, meets the water and is dissolved by it, and as the acid liquor approaches the bottom, it becomes more and more nearly saturated with gas.

The development of this process and indeed of the increased use of hydrochloric acid was the outcome of legislation against the manufacturing plants for sodium sulphate, which permitted the acid vapors to escape into the air to the detriment of surrounding vegetation and property.

Next in importance is the Hargreaves and Robinson process which has recently been made successful in a mechanical way. It depends upon the following reaction between sodium chloride, sulphur dioxide, steam and atmospheric oxygen.

$$2NaCl + SO_2 + H_2O + O = Na_2SO_4 + 2HCl.$$

It is carried out as a continous process, the temperature of the reaction being from 400° to 500° C.

Under former industrial conditions chlorine was largely manufactured from hydrochloric acid. These conditions are now occasionally reversed, owing to the immense amount of chlorine which is obtained as a by-product in the manufacture of caustic soda by electrolysis. The subsequent conversion of chlorine into hydrochloric acid takes place when chlorine and steam are heated to 1000° C. in the presence of an excess of carbon, and is according to the following reaction: $Cl_2 + H_2O + C = 2HCl + CO$. (*Ch. Ztg.,* 1912, p. 54.)

An electrolytic process is now being operated at Niagara Falls by the Roberts Chemical Company, who electrolyze potassium chloride and obtain as products potassium hydroxide and hydrochloric acid. This is done by burning the chlorine direct with the hydrogen set free at the cathode. This is known as *Synthetic Hydrochloric Acid.*

The acid, when required to be pure, is generally prepared by saturating distilled water with the gas in Woulff's apparatus. A quantity of pure fused sodium chloride is introduced into a retort or flask, placed on a sand-bath. The vessel is then furnished with an S-tube, and connected with a series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the evolution of the gas slackens, heat is applied, and gradually increased until the water in the bottles refuses to absorb any more, or until no more gas is found to come over. As soon as the process is completed, boiling water should be added to the contents of the retort or flask, in order to facilitate the removal of the residue. During the progress of the saturation, the water in the several bottles increases in temperature, which lessens its power of absorption. It is, therefore, expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

In the process for hydrochloric acid, theory calls for a little less than 90 parts of liquid sulphuric acid to 100 of common salt. A moderate excess of the former may be useful to insure the complete decomposition of the salt. The reaction for its formation is:

$$NaCl + H_2SO_4 = HCl + HNaSO_4$$

If only half the amount of sulphuric acid be used, the reaction is:

$$2NaCl + H_2SO_4 = 2HCl + Na_2SO_4$$

In the first of these reactions, as only one molecule of salt is taken, it is obvious that there is not enough sodium furnished to neutralize the sulphuric acid completely and make the normal sulphate, Na_2SO_4, so the result is the acid sulphate, $HNaSO_4$. On the other hand, in the second reaction, the two molecules of salt furnish just the sodium necessary to neutralize the one molecule of sulphuric acid and make the neutral sulphate, Na_2SO_4.

As hydrochloric acid, prepared in the ordinary mode, often contains arsenic, so as to obscure its indications when employed in testing for that poison, it is of interest to the practical toxicologist to know that it may be obtained free from that impurity by distilling sodium or potassium chloride with oxalic acid in equivalent proportions.

A method of freeing hydrochloric acid from arsenic trioxide is recommended by Engel (*J. P. C.*, 1873, p. 10) as easy and efficacious. It is founded on the fact that arsenic trioxide is reduced to arsenic by hypophosphorous acid. In another method the acid is first treated with MnO_2 and then diluted with water and allowed to stand in contact with bright copper sheets, after which it is distilled in the presence of copper. Arsenic may also be removed by taking advantage of the fact that in the presence of ferrous chloride the arsenic volatilizes easily and passes over with the first portions distilled. Traces of arsenic may also be removed by adding solution of stannous chloride, and after the precipitate of impure arsenic has settled, the clear liquid is redistilled. (Bettendorf, *Zeit. An. Chem.* [2], v, p. 492.) The best results in the removal of arsenic seem to be obtained by the process of Meister Lucius and Bruning of Hoechst (1905), in which cheap vanadous salts are employed which may be regenerated and recovered electrolytically.

Description and Physical Properties.—" A colorless, fuming liquid having a pungent odor. The fumes and odor disappear on diluting the Acid with 2 volumes of water. On distilling Hydrochloric Acid at normal barometric pressure, a stronger acid passes over first, until at 110° C. an acid of about 20 per cent. remains and this distils unchanged. Specific gravity: about 1.155 at 25° C.

" It is strongly acid to litmus paper, even when highly diluted. When Hydrochloric Acid is heated with manganese dioxide, chlorine is evolved. Hydrochloric Acid responds to the reactions for chlorides.

" Hydrochloric Acid when diluted with 2 volumes of water conforms to the following tests: Evaporate 25 cc. of the dilution and dry at 110° C.: not more than 0.003 Gm. of residue remains. Add 1 cc. of chloroform to 10 cc. of the dilution, and cautiously add, a drop at a time with constant agitation, chlorine T.S. which has been diluted with an equal volume of distilled water: the chloroform remains free from even a transient yellow, orange or violet color (*bromide or iodide*). Add 1 cc. of potassium iodide T.S. and 1 cc. of chloroform to 10 cc. of the dilution, and agitate the mixture: the chloroform remains free for at least one minute from any violet coloration (*free chlorine or bromine*). A 2 cc. portion of the dilution further diluted with 14 cc. of distilled water meets the requirements of the test for *heavy metals,* page 439. A 5 cc. portion of the dilution further diluted with 12 cc. of distilled water (without the treatment with sulphuric and sulphurous acids) meets the requirements of the test for *arsenic,* page 428. Add 5 drops of barium chloride T.S. to a mixture of 3 cc. of the dilution and 5 cc. of distilled water: neither turbidity nor precipitation appears within one hour (*sulphuric acid or sulphate*). At the end of this period, the further addition to the liquid of 2 drops of tenth-normal iodine produces neither turbidity nor decoloration of the iodine (*sulphurous acid*).

" **Assay.**—Proceed as directed under the assay for acids, page 430, using about 3 cc. of the Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03647 Gm. of HCl. "Preserve in glass-stoppered bottles." *U. S.*

"Yields, when neutralised, the *reactions* characteristic of chlorides. Specific gravity 1.160. 5 millilitres, diluted with *water,* require for neutralisation 50.6 millilitres of *N/1 solution of sodium hydroxide.* When diluted with *water* yields no characteristic *reactions* for bromides, iodides, sulphates, or sulphites, and only slight *reactions* for iron. Diluted with *water* and *solution of potassium iodide* added, no blue color is produced on the addition of *mucilage of starch* (absence of free chlorine). *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.01 per cent. by weight of residue on evaporation." *Br.*

Exposed to the air it emits white fumes, owing to the escape of the acid gas and its union with the moisture of the atmosphere. When concentrated, it blackens organic substances, as does sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1.21. The U. S. acid has the specific gravity of 1.155 at 25° C., which is practicaly equivalent to the figure given in the British Pharmacopœia, which is 1.160 at 15.5° C. When exposed to heat, it continues to give off hydrochloric acid gas, with the appearance of ebullition, until its sp. gr. falls to 1.094, when it properly boils, and may be distilled unchanged, or entirely volatilized.

Hydrochloric Acid of Commerce. Muriatic Acid.—So-called by Priestley, from *murum,* the old name of chlorine, which in turn was derived from the Latin *murias,* brine. It has a yellowish color owing to the presence of ferric chloride, or of a minute proportion of organic matter, such as cork, wood, etc. It usually contains traces of sulphuric acid, and sometimes free chlorine and nitrous acid. Sulphurous Acid was formerly a frequent impurity (for methods for its detection see tests under *Acidum Hydrochloricum Dilutum,* but is not at present an important adulterant. Arsenic, derived from sulphuric acid, used in its manufacture, and lead, from the vessels used, were also often present. The official tests will exclude these impurities for all purposes but in toxicological analysis. (For other tests see *U. S. D.,* 19th ed., p. 38.) A small proportion of thallium has been detected in commercial hydrochloric acid by Wm. Crookes, being derived from sulphuric acid, in the manufacture of which pyrites was employed. Selenium has been found in French hydrochloric acid, causing the acid to have a bad odor.

Properties of Hydrochloric Acid Gas.—Hydrochloric acid gas is colorless and elastic, possessing a very pungent odor, and the property of irritating the organs of respiration. It destroys life and extinguishes flame. It reddens litmus powerfully, and has the other properties of a strong acid. Its sp. gr. is 1.278 (Gay-Lussac and Biot). Subjected to a pressure of 40 atmospheres, at the temperature of 10° C., it is condensed into a transparent liquid, to which alone the name of *liquid hydrochloric acid* properly belongs. Water absorbs this gas with the greatest avidity.

Hydrochloric acid is found in nature in volcanic exhalations and in the waters of streams in volcanic regions, the water of the Vinagro River in the Andes containing 0.111 per cent. of HCl. It is a normal constituent of the gastric juice of all mammals and serves an important purpose in digestion.

Toxicological Properties.—Hydrochloric acid, when swallowed, is highly irritating and corrosive, but less so than sulphuric or nitric acid. It produces hiccough, violent efforts to vomit, and agonizing pain in the stomach. There is much thirst, with great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid has been recently swallowed, white vapors of a pungent odor will be emitted from the mouth. The best antidote is magnesia, but sodium bicarbonate, chalk, soap or any sufficiently diluted alkaline solution which is immediately at hand may be used. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on general principles.

Uses.—Stronger hydrochloric acid is rarely used in medicine. For a discussion of the therapeutic properties, incompatibilities, etc., see *Acidum Hydrochloricum Dilutum.*

Dose, five to ten minims (0.3–0.6 cc.) well diluted.

Off. Prep.—Acidum Hydrochloricum Dilutum, *U. S., Br.;* Acidum Nitrohydrochloricum, *N. F.;* Acidum Nitrohydrochloricum Dilutum, *N. F., Br.*

ACIDUM HYDROCHLORICUM DILUTUM. U. S., Br.

DILUTED HYDROCHLORIC ACID Acid. Hydrochl. Dil.

"Diluted Hydrochloric Acid is an aqueous solution containing not less than 9.5 per cent. and not more than 10.5 per cent. of HCl." *U. S.*

"Diluted Hydrochloric Acid contains 10 per cent. by weight of hydrogen chloride, HCl." *Br.*

Acidum Muriaticum Dilutum, U. S., 1870: Diluted Muriatic Acid; Acide chlorhydrique dilué, *Fr.;* Acidum hydrochloricum dilutum, *P. G.;* Verdünnte Salzsäure, *G.;* Acido cloridrico diluito, *It.*

"Hydrochloric Acid, 313 Gm.; Distilled Water, 687 Gm.; to make 1000 Gm. Mix them." *U. S.* "Hydrochloric Acid, 330 grammes; Distilled Water, sufficient to produce 1000 millilitres. Mix." *Br.*

The official description is as follows: "A colorless, odorless liquid. Specific gravity: about 1.049 at 25° C.

"Diluted Hydrochloric Acid is strongly acid to litmus paper. Diluted Hydrochloric Acid conforms to the tests for identity and purity under *Acidum Hydrochloricum.*

"**Assay.**—Proceed as directed under the assay for acids, using 10 cc. of Diluted Hydrochloric Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03647 Gm. of HCl.

"Preserve in glass-stoppered bottles." *U. S.*

"Yields, when neutralised, the *reactions* characteristic of chlorides. Specific gravity 1.048. 10 millilitres require for neutralisation 28.7 millilitres of *N/1 solution of sodium hydroxide.* Free from the impurities indicated under 'Acidum Hydrochloricum.'" *Br.*

Delort and Roche have proposed a colormetric method of assay for free hydrochloric acid taking advantage of the color produced when it is mixed with a solution of brilliant green.

Uses.—As is well known, hydrochloric acid is secreted by the glands of the stomach and is essential in gastric digestion for the purpose of activating pepsinogen. It probably also plays an important part in the digestive processes by determining the rapidity of the discharge of the gastric contents in the duodenum. Cannon has shown that free acid in the pyloric portion of the stomach leads to a relaxation of the pylorus and that when the duodenal contents have become acid through the discharge of the gastric contents there is a closing of this orifice. Moreover, hydrochloric acid forms with the duodenal mucous membrane a hormone known as *secretin* which stimulates the pancreas. In many cases of gastric indigestion, and probably also of intestinal indigestion, the cause of the disturbance is a diminution in the amount of hydrochloric acid secreted. The most important use of hydrochloric acid in medicine is for the purpose of replacing at least in part the lack of the natural acid in the treatment of *fermentative gastritis, nervous dyspepsia,* and similar conditions. For the same reason it is often of service to improve the digestion, and thereby the nutrition, in various *low fevers, phthisis,* and other forms of *malnutrition.* The doses which are sometimes employed are absurdly small. When we remember that the normal acidity of the stomach during gastric digestion ranges from 0.2 to 0.3 per cent. of hydrochloric acid—which would necessitate nearly two grammes of absolute hydrochloric acid for an ordinary meal—the futility of administering five to ten drops of a 10 per cent. solution of this acid is evident. Hydrochloric acid has also been highly recommended in *pernicious anemia* by Beebe and by Croftan (*J. A. M. A.,* August, 1910, p. 593), and in the treatment of *gout* by Falkenstein and others. Its value in these vases is probably due to improvement of the patient's nutrition.

Hydrochloric Acid and diluted hydrochloric acid are incompatible with lead, silver, and mercury salts; with antimony and potassium tartrate solution, a precipitate of basic chloride of antimony is produced. In bismuth and ammonium citrate, bismuth citrate is precipitated. The strong acid decomposes chlorates, nitrates, etc., with the evolution of chlorine, and other irritating gases.

Dose, ten to sixty minims (0.6–3.75 cc.) well diluted.

Off. Prep.—Acidum Hydrochloricum.

ACIDUM HYDROCYANICUM DILUTUM. Br.

DILUTED HYDROCYANIC ACID Acid. Hydrocyan. Dil.

"Diluted Hydrocyanic Acid is an aqueous solution containing 2 per cent. by weight of hydrogen cyanide, HCN. It may be obtained by the interaction of diluted sulphuric acid and potassium ferrocyanide, and subsequent distillation. Should be stored in a dark place, in small, inverted stoppered bottles of amber-coloured glass." *Br.*

Cyanhydric Acid; Diluted Prussic Acid: Acidum Hydrocyanatum, s. Borussicum; Acidum Cyanhydricum Solutum, *Fr. Cod.;* Acide cyanhydrique, dissous, *Fr.;* Cyanwasserstoffsäure, Blausäure, *G.;* Acido cianhidrico Medicinal, *Sp.*

Diluted hydrocyanic acid is no longer recognized by the U. S.

Hydrocyanic acid must be handled with great caution because of the poisonous character of its fumes even in the diluted form. No process for making this acid is official. The U. S. P. VIII gave the following extemporaneous process: "Silver Cyanide, *six grammes;* Diluted Hydrochloric Acid, *fifteen and fifty-four hundredths cc.;* Distilled Water, *forty-four and one-tenth cc.* Mix the Diluted Hydrochloric Acid with the Distilled Water, add the Silver Cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid." *U. S. VIII.*

The U. S. P., 1890, process, which may be used on a larger scale, is carried out by distilling potassium ferrocyanide with diluted sulphuric acid under carefully specified conditions. (See *U. S. D.,* 20th ed., p. 38.)

When potassium ferrocyanide is decomposed by sulphuric acid, the residue in the retort is potassium sulphate, mixed with an insoluble compound of iron cyanide and potassium cyanide (*Everitt's Salt*). The reaction is expressed by the following equation:

$$2K_4FeC_6N_6 + 3H_2SO_4 = 3K_2SO_4 + 2KFeC_3N_3 + 6HCN$$

Half of the cyanogen present in the potassium ferrocyanide goes to form the hydrocyanic acid, while the other half remains in the white residue. Everitt's salt, so named from its discoverer, is a yellowish-white powder. Like potassium ferrocyanide, it is a double salt (iron and potassium cyanide), but of different molecular ratio. As it appears in practice, it is apt to be greenish, owing probably to the presence of a little Prussian blue.

Investigations have shown that potassium ferrocyanide is decomposable not only by the weakest acids but also by numerous non-acid organic substances, hydrocyanic acid being liberated; thus the diluted mineral acids (containing even less than 0.1 per cent.), formic, acetic, butyric, lactic, tartaric, benzoic acids, even carbon dioxide and hydrogen sulphide, phenols, peptones, casein, etc., will decompose potassium ferrocyanide more or less quickly at temperatures below 100° C., liberating a portion of the hydrocyanic acid. (*A. J. P.*, 1893, p. 283.)

Hydrocyanic acid may also be made by passing a mixture of trimethylamine and ammonia through a red hot tube. $N(CH_3)_3 + 2NH_3 = 3HCN + 12H$.

The processes thus far given are intended to furnish a *diluted* hydrocyanic acid for medicinal purposes. For processes for making the *anhydrous* acid, see U. S. Dispensatory, 19th ed., p. 40.

Berthelot has made hydrocyanic acid synthetically. He first prepared, by a direct synthesis of its elements, *acetylene* (C_2H_2). He then mixed this gas with pure nitrogen, passed a series of electric discharges from a Ruhmkorff coil through the mixture, and, when the odor of prussic acid was perceptible, agitated with a solution of potassium hydroxide to get the fixed cyanide. It has also been made by heating chloroform with ammonia and potassium hydroxide solution. (Hofmann.)

Properties of the Diluted Acid.—Diluted hydrocyanic acid is officially described as "a colorless liquid with a characteristic odor. Specific gravity is 0.997. Only slightly acid to litmus. Yields when neutralised the reactions characteristic of cyanides. 5 millilitres, mixed with 50 millilitres of *water,* 5 millilitres of *solution of ammonia,* and 3 drops of *solution of potassium iodide,* require the addition of not less than 18.4 and not more than 19 millilitres of *N/10 solution of silver nitrate* before a permanent precipitate begins to form. 5 millilitres evaporated in a platinum dish leave no appreciable residue. Yields not more than the slightest characteristic *reactions* for sulphates or chlorides." *Br.*

It is liable to undergo decomposition if exposed to the light, but it may be kept for a longer time in a bottle covered with black paint or black paper. From experiments carefully conducted by Bussy and Buignet, it appears that, when the alteration in the acid under the influence of light has begun, it will afterwards go on very rapidly in the dark; and that after exposure for a certain time to the light, though no alteration may be apparent, an influence has nevertheless been exerted which disposes to change, and promotes decomposition even in the absence of light. Hence the necessity of immediately enclosing the acid in bottles from which the light is excluded. Experience has shown that it is best preserved in cork-stoppered bottles of amber glass; when glass and rubber stoppers were used, decomposition frequently takes place rapidly.

Leivcock (*P. J.*, 1918, p. 50) discusses the various causes of decomposition of hydrocyanic acid, which are mainly due to the presence of alkalies. He states that the best preservatives are small amounts of sulphuric or tartaric acid. The U. S. IX permitted the presence of 0.1 per cent. of hydrochloric acid.

"**Assay.**—Pour about 5 mils of Diluted Hydrocyanic Acid into a 100 mil flask containing 25 mils of distilled water and 5 mils of potassium hydroxide T.S., the whole having been previously tared, and weigh the Acid accurately. Then add 3 drops of potassium iodide T.S. and titrate with tenth-normal silver nitrate V.S. to the production of a slight, permanent precipitate. It shows not less than 1.9 per cent. nor more than 2.1 per cent. of HCN.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.005404 Gm. of HCN. Each gramme of Diluted Hydrocyanic Acid corresponds to not less than 3.5 mils nor more than 3.9 mils of tenth-normal silver nitrate V.S." *U. S. IX.*

Formerly the medicinal acid was of different strengths, as ordered by the different pharmaceutical authorities, but the Br. now conforms with the International Protocol. At one time its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this inaccurate method is not now relied on, though the British Pharmacopœia gives the sp. gr. of its diluted acid at 0.997.

In connection with the determination of the minute amounts of hydrocyanic acid encountered in work on cyanogenetic plants, Viehoever and Johns have published a method in *J. Am. C. S.*, 1915, based upon a colorimetric comparison with a standard suspension of Prussian blue.

Properties of the Anhydrous Acid.—*Hydrocyanic acid,* perfectly free from water, is a colorless, transparent, inflammable liquid, of extreme volatility, boiling at 27° C., and congealing at –15° C. Its sp. gr. as a liquid is 0.6969, at the temperature of 18° C.; and as a vapor 0.9423. Its vapors are highly poisonous.

Anhydrous prussic acid is now supplied, commercially, compressed in metal cylinders. Large quantities are used in California in combating certain diseases of the citrus trees.

It was discovered in 1815 by Gay-Lussac, who viewed it as a compound radical which when combined with hydrogen becomes hydrocyanic acid. Hydrocyanic acid, in a diluted state, was discovered in 1780 by Scheele, who correctly stated its elements to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac by whom also the anhydrous acid was first obtained.

Hydrocyanic acid is one of the products of the decomposition of the cyanogenetic glucosides. These plant principles are widely distributed being found in at least a dozen natural orders of plants. The *Prunus* family is especially noted for the occurrence of this cyanogenetic glucoside *amygdalin.* Others are *dhurrin* from sorghum, *cotusin* from Lotus *arabicus,* and *phaseolunatin* from the seeds of certain beans and in species of Manihot which yield tapioca. A method for the detection of minute amounts of hydrocyanic acid based upon the formation of a sulphocyanide, is proposed by Lavaille and Varenne (*J. P. C.,* 1918, p. 97). It is stated that .005 milligramme can be detected by this test.

Uses.—Moderate doses of hydrocyanic acid and the cyanides cause marked increase in both the rate and depth of respiration and with a marked rise in blood pressure accompanied by a slowing of the pulse. These effects are due to increased activity of the respective centers in the medulla. Gepper (*Z. K. M.,* 1889, xv, 208–307) has shown that the cyanides lessen oxidative processes in the body and Gasser and Loevenhart (*J. P. Ex. T.,* 1914, v, 139) attribute the stimulation of the medullary centers to the deficiency in oxygen. The stimulation of these centers lasts but a very short time and if the dose has been large enough is followed by a marked depression. According to Loevenhart (*A. I. M.,* 1918, xxi, 109) by giving small doses at short intervals it is possible to maintain the stimulating effects for a long period of time. Somewhat paradoxically Loevenhart (*J. P. Ex. T.,* 1922, xix, 13) has shown that when the respiratory center is depressed by cerebral ischemia the cyanides are still capable of acting as respiratory stimulants. Diluted hydrocyanic acid has been much used in respiratory diseases and to quiet *cough,* but its action is so fugacious that it has really very little medicinal value except as a local remedy in sick stomach of nervous origin and in *gastrodynia.* Externally, it may be of occasional service in *pruritus,* but should be used circumspectly, as its vapors are poisonous.

It should be administered with the greatest caution, on account of its minute dose and its variable strength as usually found. The proper plan, therefore, is to begin with a small dose, two drops, for example, and gradually to increase the quantity until some obvious impression is produced. On account of the rapidity and uncertainty of its action, it should be given at intervals of not more than two hours; indeed, it is very improbable that the largest therapeutic dose of the substance exerts any influence whatever upon the system one hour after its ingestion. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. As a lotion it may be diluted with from eight to fifteen parts of water.

Gaseous hydrocyanic acid is used in public hygiene for the destruction of vermin in buildings (see *J. Soc. Chem. Med.,* 1920, xxxix, 794). It is also used by trappers by placing a small triangular ampule containing a few drops of the acid, in a bait in such a manner that the ampule is crushed by the teeth of the animal when the bait is taken.

Diluted Hydrocyanic Acid is incompatible with the strong mineral acids which decompose it to formic acid and a salt of ammonium. Calomel is changed into mercuric chloride. It is also incompatible with salts of silver, lead and mercury. Oxidizing agents destroy it with the formation of a number of compounds.

Toxicology.—Hydrocyanic acid is an exceedingly powerful poison acting with great rapidity. After large doses death may take place in from two to ten minutes, but from minimal fatal quantities may be delayed as long as two or three hours. The smallest fatal quantity upon record seems to be that reported by Garstang (*L. L.,* 1888, ii, p. 15), in which 2 drachms of the 2 per cent. solution proved fatal. The ordinarily fatal does is about 1 to 1½ grains of the pure acid. Of potassium cyanide the ordinarily fatal dose is about five grains.

After large doses the progress of the poison is so rapid that one can scarcely speak of symptoms; the patient gives a cry and falls down insensible and respirations which are at first hurried become in a few seconds slow and gasping and death may occur in a few minutes either with or without preceding convulsions. In the majority of cases, however, the poison progresses somewhat more slowly and the symptoms will be as follows: Immediately after swallowing the poison there is a sense of constriction in the throat followed by salivation and nausea with vertigo and headache. The respirations are at first rapid and then become slow and irregular, with expiration often being greatly prolonged. The pulse is slow and at first bounding, the pupils dilated and insensible to light, the eyes wide open and staring, the skin cold and cyanotic, and violent convulsions with foaming of the mouth are not uncommon. This stage is followed by one of weakness, the patient becoming unconscious, the temperature falling, the pulse growing feeble, the respirations very slow and gasping in character. Death is the result of asphyxia and the symptoms are those, in general, characteristic of interference with oxygenation. Post mortem the blood may be either of a uniform arterial hue in both veins and arteries or the dark blood of cyanosis, according as to whether death has taken place rapidly or slowly.

The treatment of prussic acid poisoning to be of any avail must be undertaken with great promptness. The stomach should be immediately emptied with the pump, as emetics often fail to produce the desired effect. Among the chemical antidotes which have been suggested the most useful are the ferric salts suggested by T. and H. Smith. Martin and O'Brien (*Pro-*

ceedings of the Soc. for Chemical Industry, Victoria, i, p. 119) recommend that in mines, etc., where accidental poisoning is likely to occur, there should be kept on hand one ounce each of a 23 per cent. solution of ferrous sulphate, of a 5 per cent. solution of potassium hydroxide, and 30 grains of magnesium oxide. These are to be mixed in a half pint of water before being used. Cobaltous nitrate has been recommended, but, although an efficient antidote, it is so poisonous that its use in the human subject seems hardly justifiable. Kobert and Krohl (*Arb. d. Pharm. Inst. z. Dorpat,* 1891, vii; *Ph. Centralh.,* 1891) have found that in the lower animals good results may be achieved in the poisoning by the conversion in the system of the prussic acid into oxamide by means of peroxide of hydrogen. The oxamide is itself somewhat poisonous, and after its production it is essential to give large draughts of water to wash it out of the system. It is affirmed that in various mining and extracting establishments, and in certain chemical works, where the cyanides are used in enormous quantities, Kobert's method is practically employed, and Merck furnishes what is known as an "antidote-box," containing the necessary apparatus and the supply of hydrogen peroxide. (See *M. A.,* ii, p. 94.) When the cyanide has been taken into the system the peroxide must be introduced by means of a stomach tube into the stomach itself, and the latter should then be washed out. Before or immediately after the administration by the mouth the salts should be given hypodermically. In cases of poisoning by inhalation the antidote should be used subcutaneously. The poison's action is, however, so rapid that there is rarely time for any antidote to be of value. Atropine, which has been suggested as physiologically antagonistic to hydrocyanic acid, has no antidotal value.

Dose, of diluted hydrocyanic acid, one to four minims (0.06–0.25 cc.).

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.*

ACIDUM HYPOPHOSPHOROSUM. U. S.

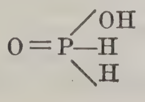
HYPOPHOSPHOROUS ACID Acid. Hypophos.

"Hypophosphorous Acid is an aqueous solution containing not less than 30 per cent. and not more than 32 per cent of HPH_2O_2." *U. S.*

Acide hypophosphoreux, *Fr.;* Unterphosphorigesäure, *G.*

Hypophosphorous acid is obtained by heating a concentrated solution of sodium hydroxide or other alkali with phosphorous. The alkaline hypophosphite is converted into a barium salt which is then decomposed with sulphuric acid and purified by crystallization.

Hypophosphorous acid is a monobasic acid since the molecule contains only one ionizable hydrogen atom as shown by the following structural formula:



It has a great affinity for oxygen which transforms it into phosphoric acid. It is therefore one of the most valuable reducing agents in chemistry and is frequently used in pharmacy as a preservative for easily oxidizable compounds. When heated, it is resolved into hydrogen phosphide and phosphoric acid. Its salts are generally soluble in water and deliquescent, and many are soluble in alcohol. They are converted into phosphates by heat, with the escape of hydrogen phosphide; some are explosive. *Calcium hypophosphite* has been most largely employed.

Description and Physical Properties.—"A colorless or slightly yellow, odorless liquid. When the Acid is heated in a suitable dish, water evaporates, leaving a more concentrated acid. On further heating between 130° and 140° C., it decomposes, forming spontaneously combustible hydrogen phosphide and phosphorous acid. The latter, between 160° and 170° C., decomposes into hydrogen phosphide and phosphoric acid. The pasty residue finally reddens, ignites, and the last portions of unoxidized phosphorus burn out at a higher temperature. Specific gravity: about 1.130 at 25° C.

"It is acid to litmus paper even when highly diluted. Hypophosphorous Acid responds to the reactions for hypophosphites. Hypophosphorous Acid diluted with 3 volumes of water conforms to the following tests for identity and purity: Neutralize 30 cc. of the dilution with ammonia T.S.: not more than a slight precipitate results. Filter, acidulate 10 cc. of the filtrate with hydrochloric acid, and add 2 cc. of potassium sulphate T.S.: no turbidity is produced (*barium*). Another 10 cc. portion of the filtrate shows no turbidity upon the addition of 1 cc. of calcium chloride T.S. (*oxalate*). One cc. of the dilution mixed with 9 cc. of distilled water meets the requirements of the test for *heavy metals.* Mix 5 cc. of the dilution with 3 cc. of nitric acid and 10 cc. of distilled water, and evaporate the liquid to dryness on a water bath: the residue meets the requirements of the test for *arsenic.*

"**Assay.**—Proceed as directed under the assay for acids, page 430, using about 7 cc. of the Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06606 Gm. of HPH_2O_2.

"Preserve in glass-stoppered bottles." *U. S.*

A new method of assay for hypophosphorous acid and the hypophosphites has been proposed by T. T. Cocking and J. T. Kettel (*Tr. Br. Ph. Conf.,* 1913, 518), which is more accurate and expeditious than any hitherto proposed. It is as follows: Two and one half Gm. of the hypophosphite (or the acid) are dissolved in 40 cc. of water and an excess of lead acetate solution (10 per cent.) added to precipitate phosphites (5 cc. is usually sufficient) and the solution is made up to 50 cc., well shaken and allowed to stand until the supernatant liquid is clear. Then 10 cc., representing 0.5 Gm. of the material taken, is carefully pipetted off, 50 cc. of normal potassium dichromate and 10 cc. of sulphuric acid added and the mixture heated on a water bath. After one hour the solution is cooled and diluted with distilled water to 250 cc. The excess of dichromate is then determined in 50 cc. of the solution by titration with tenth normal sodium thiosulphate V.S., after adding potassium iodide. The reaction upon which calculations are based is as follows:

$$R'.PH_2O_2 + O_2 = R'H_2PO_4.$$

The authors gave the method a thorough trial with a number of samples of hypophosphites obtained in the market.

The U. S. IX also recognized under the name of *Acidum Hypophosphorosum Dilutum* (*Diluted Hypophosphorus Acid*) a solution containing 10 per cent. of hypophosphorus acid which was made by mixing 100 grams of the strong acid with 210 Gm. of distilled water.

Hypophosphorous Acid is incompatible with many substances on account of its powerful reducing properties, and in exercising these effects it is oxidized to phosphoric acid and thus loses its own identity. It reduces bismuth, mercuric, and mercurous compounds to the metallic state. Ferric and cupric compounds are reduced to ferrous and cuprous. Permanganates are changed to managanous compounds; arsenates are reduced to arsenites and sometimes to metallic arsenic. With some oxidizing agents like potassium chlorate, it must not be triturated for fear of causing an explosion.

Uses.—Hypophosphorus acid was formerly believed to exert upon the nervous system a tonic effect like that of elemental phosphorus, but it has been demonstrated that the salts of this acid pass through the system unchanged and therefore cannot exert the influence of phosphorus. The present Pharmacopœia recognizes this acid only because of its use in the preparation of syrup of ferrous iodide.

ACIDUM LACTICUM. U. S., Br.

LACTIC ACID Acid. Lact.

"A mixture of lactic acid and lactic anhydrides equivalent to a total of not less than 85 per cent. and not more than 90 per cent of $CH_3.$-CHOH.COOH." *U. S.*

"Lactic Acid is an aqueous solution containing not less than 75 per cent. by weight of hydrogen lactate, $HC_3H_5O_3$, and not less than 10 per cent. by weight of lactide, $C_6H_8O_4$. It may be obtained by the fermentation of lactose." *Br.*

Alphahydroxypropionic Acid, Oxypropionic Acid, Ethylidenelactic Acid, Isolactic Acid; Acide lactique, *Fr. Cod.;* Acidum lacticum, *P. G.;* Milchsäure, *G.;* Acido lactico, Sp.

Lactic acid was discovered in 1780 by Scheele. It exists in sour milk, and is a product of the viscous or lactic fermentation of rice water, or of the juices of the beet, turnip, and carrot, and is a normal constituent of sauer kraut and of ensilage. Pasteur demonstrated that the lactic acid fermentation, like the vinous, is caused by a peculiar micro-organism. It is attended with the production not only of lactic acid, but of other substances also, and among them a peculiar gum-like substance, in abundance, which, first noticed by Kirchof, has been isolated in a pure state by Brüning. Though similar to arabin and dextrin, with the formula $C_6H_{10}O_5$, it is not exactly identical with either. The lactic acid of fermentation is one of four isomeric acids possessing the formula $C_3H_6O_3$. The *first* of these is the official lactic acid, and is inactive optically. The *second* is identical chemically with this, but dextrorotatory, and is found in the juice of flesh. It is called *paralactic acid.* The *third,* or *ethylene lactic acid,* is found mixed with the second in the so-called *"sarcolactic"* acid extracted from meat. The *fourth* acid has only been obtained synthetically, and is known as *hydracrylic acid.*

Preparation.—Lactic acid occurs in milk as a result of the decomposition of lactose. The earlier methods for its manufacture were all of them based upon the fermentation of milk or whey (for details see *U. S. D.,* 20th Ed., p. 43). It is now known that other saccharine matters such as glocose or sucrose can be made to undergo the lactic fermentation.

There are a number of species of bacteria which will produce more or less lactic acid when cultivated in a sugar-containing medium. The one generally regarded, however, as the special lactic acid ferment is the *Bacillus acidi lactici.* (See also under *Lac Fermentatum.*)

Alan A. Claflin thus describes the manufacture of lactic acid as carried out on a large scale under the patent of Charles E. Avery (*J. Soc. Chem. Ind.,* June 30, 1897): A saccharine solution varying in density from 1.05 to 1.075 is taken. This will contain from 7.5 to 11 per cent. of saccharine matter. It is advantageous to have from 10 to 15 per cent. of this, cane sugar, the rest being grape sugar. The saccharine solution, having been made up and boiled for an hour to insure sterilization, is conveyed into the fermentation tank and cooled to from 55° to 45° C., and then impregnated with nitrogenous matter (such as is extracted from bran by the action of boiling water and diluted acid) in amount equal to about 8 per cent. of the saccharine matter, and inoculated with the *Bacillus acidi lactici.* In continuous manufacture the ferment solutions are impregnated from a preceding ferment liquor in which a lively fermentation is in progress; 20 per cent. of such impregnating liquor may be added. The impregnation having taken place at 45° C. or over, the temperature is allowed to decrease somewhat as the fermentation proceeds. The glucose is practically all decomposed, and the yield of lactic acid is over

98 per cent. of the theoretical amount. As the fermentation progresses the solution must be neutralized with milk of lime, as the limits of acidity in which lactic acid bacteria are healthy are rigidly confined between 0.02 and 0.5 per cent. If the fermenting solution is overneutralized, the butyric ferment will immediately begin to act, and once active is difficult to control. The lactic fermentation is best completed in from three to six days, and when the fermentation is ended, the liquor must be heated sharply to kill all bacteria and spores and prevent subsequent fermentation. The solution is now filtered and evaporated, when calcium lactate may be crystallized out; or if commercial syrupy acid only is required, the solution may be at once decomposed by sulphuric acid. Chemically pure lactic acid is obtained by converting calcium lactate into zinc lactate with zinc carbonate, precipitating the zinc with H_2S, passing through animal charcoal and evaporating *in vacuo.*

Kiliani (*B. Chem. G.*, 1882, xv, 136 and 699) has found that lactic acid may be readily prepared by the action of potassium or, preferably, sodium hydroxide upon either grape sugar or invert sugar (*i.e.*, cane sugar after treatment with diluted acids.). He found that invert sugar gave a better yield than ordinary glucose.

His method for the preparation of lactic acid is as follows: 500 grammes of cane sugar are placed with 150 grammes of water and 10 cc. of the sulphuric acid, in a stoppered flask of 2 liters' capacity and heated for 3 hours to about 50° C. The solution of invert sugar so obtained is colorless, or at most faintly yellow. After cooling there is to be added to it in portions of 50 cc. at a time 400 cc. of a caustic soda solution made by dissolving 1 part of caustic soda in 1 part of water. The strong alkali settles at first as a slimy mass on the bottom, and a new portion is only to be added when the mixture has become perfectly homogeneous by shaking. The flask should also be cooled with water while the alkali is being added. The mixture nevertheless becomes colored and greatly heated. Finally the mixture is heated to 60° or 70° C. until a portion heated over a boiling water bath does not separate cuprous oxide from Fehling's solution, but gives it only a slight greenish tinge. Into the cooled mixture the calculated amount of sulphuric acid (made by mixing 3 parts of sulphuric acid with 4 of water) is then run. As soon as the acid liquid has cooled to the temperature of the room a crystal of sodium sulphate is dropped in and the flask dipped in cold water until a thin crystalline crust forms on the sides, which is removed by a rapid shaking of the flask. Cooling and shaking are continued until the crust no longer forms, when the mixture is allowed to stand at rest for twelve to twenty-four hours. At the end of this time the contents of the flask appear to consist of a crystalline cake soaked with a reddish liquid. There is then added alcohol of 93 per cent., and the whole is shaken up until on further addition no precipitate separates out. The precipitated sodium sulphate is freed from the alcoholic solution by a vacuum filter, and can be washed with relatively very little alcohol. The half of the alcoholic solution is neutralized over the water bath with zinc carbonate, filtered boiling hot, and united with the other half. The crystallization begins immediately upon cooling, and is complete after standing 36 hours. The zinc lactate so obtained can be pressed free from mother liquor and crystallized once, when it is perfectly pure. The weight of this first crystallization amounts to from 30 to 40 per cent. of the sugar used. The concentrated mother liquor yields yet another portion of nearly pure, although slightly yellowish, crystals. The zinc lactate may then be treated with hydrogen sulphide to remove the zinc.

Beckers (*Ap. Ztg.*, 1899, 400) patented a process for making lactic acid from the liquors obtained in the manufacture of "sauer kraut" which were formerly wasted. The liquor is neutralized with lime, filtered, evaporated and set aside to crystallize; the calcium lactate is purified, if necessary, by washing or recrystallization and then dissolved in cold water and the solution treated with sufficient sulphuric acid to set free the lactic acid. Lactic acid is also made from the liquid cheese residues. For a method of making lactic acid from corn meal, see *N. R.*, 1882, p. 235.

Description and Physical Properties.—"A colorless, or slightly yellow, nearly odorless, syrupy liquid. It absorbs moisture on exposure to air. Lactic Acid is miscible with water, alcohol, and ether, but is insoluble in chloroform, petroleum benzin, and carbon disulphide. Specific gravity: about 1.206 at 25° C. Lactic Acid cannot be distilled without decomposition.

"Lactic Acid is strongly acid to litmus paper and responds to the reactions for lactates.

"Ash: not more than 0.006 Gm. from 5 cc. of the Acid. Ten cc. portions of an aqueous dilution of the acid (1 in 100) remain unaffected by the addition of 1 cc. of silver nitrate T.S. (*chloride*), or 1 cc. of barium chloride T.S. (*sulphate*). The addition of 1 cc. of copper sulphate T.S. to 10 cc. of an aqueous dilution of the acid (1 in 20) causes no turbidity (*sarcolactic acid*). No turbidity is produced on heating the Acid with an excess of calcium hydroxide T.S. (*citric, oxalic, phosphoric, or tartaric acid*). Add a few drops of Lactic Acid to 10 cc. of hot alkaline cupric tartrate V.S.: no red precipitate is produced (*sugars*). Carefully superimpose 5 cc. of Lactic Acid upon an equal volume of sulphuric acid in a clean test tube, and keep the temperature at 15° C.: no dark color develops at the zone of contact of the two liquids upon standing for fifteen minutes (*readily carbonizable substances*). An aqueous dilution of the Acid meets the requirements of the test for *heavy metals*.

"Preserve in glass-stoppered bottles." *U. S.*

"Specific gravity about 1.21. Warmed with one-tenth of its weight of *potassium permanganate* it yields the odor of aldehyde. 1 gramme diluted with 10 millilitres of *water* requires for neutralisation not less than 8.3 millilitres of *N/10 solution of sodium hydroxide.* After the further addition of 10 millilitres of the alkaline solution and boiling for fifteen minutes, not more than 8.6 millilitres of *N/1 solution of sulphuric* acid are required to neutralise the excess of alkali. Yields no characteristic *reactions* for copper, iron, chlorides, citrates, oxalates, phosphates, sulphates, or tartrates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Diluted with *water* gives no precipitate with *solution of copper sulphate* (absence of sarco-lactic acid), and none, or only the slightest traces, with excess of *solution of potassio-cupric tartrate,* even after prolonged boiling (absence of more than traces of various sugars). The mixture obtained by heating Lactic Acid with excess of *zinc carbonate* and evaporating to dryness, when exhausted with *absolute alcohol* and the latter evaporated, does not leave any sweet residue (absence of glycerin). Yields no rancid odor when gently warmed (absence of fatty acids). When carefully poured upon an equal volume of *sulphuric acid* contained in a clean test tube, little or no darkening in color occurs (absence of organic impurities). No turbidity, whether permanent or transient, is produced when the Acid is added drop by drop to twice its volume of *ether* (absence of gum, sugars, mannite, calcium phosphate). Yields no precipitate with *solution of lead subacetate* (absence of malic acid and sulphuric acid)." *Br.*

Exposed to a temperature of 150° C., it is for the most part converted into a new body, which is called concrete lactic acid or *lactide,* an anhydride having the formula $C_6H_8O_4$. It coagulates albumin and dissolves a large quantity of freshly precipitated calcium phosphate, a property which doubtless renders it important in the animal economy.

Assay.—"Add 50 cc. of normal sodium hydroxide to about 2.5 cc. of Lactic Acid, accurately weighed, in a tared 250 cc. flask, and boil for twenty minutes. Titrate the excess of alkali in the hot solution with normal sulphuric acid, using phenolphthalein T.S. as indicator. Make a blank test, using 50 cc. of half-normal sodium hydroxide, and from the comparisons make any necessary corrections. Each cc. of normal sodium hydroxide corresponds to 0.09006 Gm. of $CH_3.CHOH.COOH$." *U. S.*

Of the organic acids lactic acid is the only one oxidized by chromic acid in the presence of sulphuric acid, to acetic acid and carbonic acid. An assay process based upon this principle has been devised by Szberenyi who claims results within three per cent. of the theoretical amount. (*Pharm. Weekblad.*, 1918, lv, 1041).

Lactic acid has the incompatibilities of the organic acids in general, but is also incompatible with oxidizing agents which convert it into aldehyde, oxalic acid etc. Hydriodic acid decomposes lactic acid with the production of propionic acid.

Uses.—Lactic acid was formerly used for the removal of *phosphatic deposits* in the urine and in certain types of *diarrhea.*

Hypnotic properties have also been ascribed to lactic acid, but the claim has not been verified. It is no longer employed as an internal remedy.

In concentrated form lactic acid is an active caustic; when diluted it is stimulant and germicidal. The 50 to 80 per cent. solution has been used as a caustic antiseptic in *infected wounds, ozena, laryngeal tuberculosis,* etc.; the 20 per cent. solution has been used for the destruction of false membrane in *diphtheria;* the three per cent. solution has been strongly recommended by Sneguirewa for irrigation in foul *leucorrheas.* (For consideration of the therapeutic uses of the lactic acid forming bacteria see under *Kephir,* Part II.)

Dose, from fifteen to forty-five minims (1–3 cc.).

ACIDUM NITRICUM. U. S., Br.

NITRIC ACID Acid. Nitric.

"Nitric Acid contains not less than 67 per cent. nor more than 69 per cent of HNO_3." *U. S.* "Nitric Acid contains 70 per cent. by weight of hydrogen nitrate, HNO_3, and 30 per cent. by weight of water. It may be obtained by the interaction of sulphuric acid and sodium nitrate." *Br.*

Acidum Nitri, s. Azoticum, Spiritus Nitri Acidus; Spirit of Nitre; Aqua Fortis; Acide azotique officinal, *Fr. Cod.;* Acide nitrique, *Fr.;* Acidum nitricum, *P. G.;* Salpetersäure, *G.;* Acido nitrico concentrato, *It.;* Acido nitrico, *Sp.;* Zaltpeterzuur, Sterkwater, *Dutch;* Shedwater, *Sw.*

Nitric acid oxide is one of the five compounds formed by nitrogen and oxygen. These are, nitrogen monoxide or hyponitrous oxide (laughing gas), N_2O; nitrogen dioxide, N_2O_2, or NO; nitrous oxide, N_2O_3; nitrogen tetroxide or peroxide, N_2O_4; and nitric oxide, N_2O_5. From this latter by the addition of water is formed nitric acid:

$$N_2O_5 + H_2O = 2HNO_3$$

The nitric acid of the British Pharmacopœia is slightly stronger than that of the U. S. containing 70 per cent. of HNO_3 as against 67 to 69 per cent.

Preparation.—Nitric acid is made by decomposing sodium nitrate with sulphuric acid. The reaction is as follows:

$$NaNO_3 + H_2SO_4 = NaHSO_4 + HNO_3.$$

This reaction takes place below 200° C.

At higher temperatures the sodium acid sulphate may be made to react with another molecule of sodium nitrate and normal sodium sulphate, Na_2SO_4, is produced, but in practice the reaction is rarely forced up to the second phase on account of some practical disadvantages connected with the removal of the by-product from the still.

The by-product, acid sodium sulphate, has found but a limited use and is practically given away free of charge to get rid of it. Formerly it was the custom to use glass retorts in the manufacture of nitric acid, but they have been abandoned in favor of cast iron retorts, the vapors being condensed in stoneware vessels. These condensers are so arranged that the various gases produced as variants or by-products of the reaction, such as N_2O_3, HCl, NOCl, O, and the halogens, if present, are collected and obtained separately, so that instead of the first distillation producing a very impure nitric acid which required subsequent redistillation and purification, a pure nitric acid is obtained directly. This method is now said to yield 650,000 tons annually in the United States alone.

During recent years nitric acid has been manufactured from atmospheric nitrogen by causing it to combine directly with oxygen through the heat of an electric arc. This is known as the Birkeland-Eyde process. This forms nitric oxide which, as the temperature falls, is converted into nitrogen peroxide. This latter gas is led into granite towers filled with broken quartz where it meets with falling water, with the elements of which it unites to form a dilute nitric acid. (See Strong, *A. J. P.*, 1915, p. 39.) A modification of this method in which rarified air and an excess of oxygen are used, is the Haber process. Another method of utilization of atmospheric nitrogen is by burning carbon monoxide in the presence of air in closed chambers, under pressure, and by rapidly cooling the flame against a cold surface. Still another method is by transforming ammonia into nitric acid by mixing it with air and passing it over spongy platinum heated to 300° C. Other catalyzing agents, such as thorium or tellerium oxides, have been employed. This method is said to be six times as efficient as the arc process, especially when nitrogen concentrated from liquid air is employed. Nitric acid has also been prepared industrially from synthetic calcium nitrate which is one of the modern products of the electric furnace.

Lunge and Rey obtained pure, colorless, concentrated nitric acid by the following method: A quantity of nitric acid, prepared and deprived of coloring impurities in the usual manner, and containing 98.7 per cent. of absolute nitric acid, was put into a retort together with twice its volume of absolute sulphuric acid (H_2SO_4), and distilled *in vacuo*, the pressure being reduced to 20 mm. by means of a water-jet pump. This was found to be the only way to prevent the acid from becoming yellow. The connection between the neck of the retort and the receiver was effected by wrapping with asbestos paper and an external coat of moulder's clay. Great care was taken to insure the absence of organic matter. The distillation takes place at a temperature of 35° C. and the distillate was completely colorless. It contained 99.7 per cent. of HNO_3. (*Am. Drug.*, June 1, 1891, 170; from *Zeit. An. Chem.*)

Monohydrated Nitric Acid. Hydrogen Nitrate.—This is the strongest liquid nitric acid that can be procured, and may be obtained by distilling one molecule of pure and dry sodium nitrate with one molecule of monohydrated sulphuric acid. One molecule of monohydrated nitric acid distils over, and one molecule of sodium bisulphate remains behind: Acid of this strength is very difficult to make, and requires for its preparation the most elaborate attention to separate the superabundant water. According to Arthur Smith, of London, acid dehydrated as far as possible is perfectly colorless, boils at 84° C., and has the sp. gr. 1.517 at 15.4° C., and nearly approaches, in composition, to a monohydrate. Acid of this strength, even at the boiling temperature, has not the slightest action on tin or iron. According to Kolb (*Ann. Ch. Phys.* [4], x, 140), the true HNO_3 has a sp. gr. at 15° C. as high as 1.530.

The acid of a former Br. Pharmacopœia, having the sp. gr. 1.5, is of a yellowish color, and strongly corrosive. Strictly speaking, it is hydrogen nitrate diluted with half a molecule of water. An acid of this strength is inconveniently strong, is constantly undergoing decomposition under the influence of light. Besides, acid of this density was not necessary for any process of the Pharmacopœia. These considerations led to a reduction in the strength of both the U. S. and British Pharmacopœias to their present strengths. The specific gravity 1.40 given in the U. S. Pharmacopœia is practically equivalent to that given in the U. S. Pharmacopœia of 1890 (1.414), the temperature used in the U. S. Pharmacopœia for specific gravity being 25° C. instead of the lower one of 15.6° C.

For official tables of specific gravity of various strengths of nitric acid, see Part III.

Description and Physical Properties.—"A fuming liquid, very caustic and corrosive and having a characteristic, highly irritating odor. It boils at about 120° C., but volatilizes completely when heated on a steam bath. Specific gravity: about 1.40 at 25° C.

"Nitric Acid is strongly acid to litmus paper, even when highly diluted. Nitric Acid responds to the reactions for nitrates. Nitric Acid acts upon copper, mercury, silver, and many other metals with the evolution of brownish-red fumes, and stains woolen fabrics and animal tissues a bright yellow.

"Evaporate 20 cc. of Nitric Acid from a platinum or porcelain dish, and dry at 110° C.: not more than 0.003 Gm. of residue remains (*non-volatile substances*). Shake 2.5 cc. of Nitric Acid, diluted with 7.5 cc. of distilled water, with 2 cc. of chloroform: the latter remains colorless (*iodine or bromine*) even after the introduction of a small piece of metallic tin (*iodic or bromic acid*). Nitric acid diluted with 25 volumes of distilled water and neutralized with ammonia T.S., meets the requirements of the test for *heavy metals.* The residue remaining from the evaporation of 0.5 cc. of Nitric Acid to dryness on a water bath meets the requirements of the test for *arsenic.* Separate portions of Nitric Acid diluted with 10 volumes of distilled water do not yield a precipitate upon the addition of barium chloride T.S. (*sulphate*), or of silver nitrate T.S. (*chloride*).

"Preserve in dark amber-colored, glass-stoppered bottles, protected from light." *U. S.*

"A clear, colorless, or almost colorless liquid emitting corrosive fumes. Yields, when neutralised, the *reactions* characteristic of nitrates. Specific gravity 1.42. 1 gramme diluted with *water* requires for neutralisation 11.1 millilitres of *N/1 solution of sodium hydroxide.* When diluted with *water* yields no characteristic *reactions* for copper, iron, chlorides, bromates, iodates, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.05 per cent. by weight of residue on evaporation." *Br.*

Acid of the density 1.42 at 15° C. is the most stable of the hydrated compounds of nitric acid, and boils at 121° C., the U. S. P. acid boiling at 120.5° C. When either stronger or weaker than this, it distils over at a lower temperature, and, by losing more acid than water in the first case, and more water than acid in the second, constantly approaches to the sp. gr. 1.42, when its boiling point becomes stationary. Dalton first observed these facts in relation to nitric acid of this strength, which have been confirmed by Arthur Smith, of London. This acid may be assumed to have the composition $HNO_3 + 1\frac{1}{2}H_2O$.

The reddish acid called *aqua fortis* or *nitrous acid* is nitric acid containing more or less nitrogen tetroxide (N_2O_4). The same acid may be formed by impregnating, to a limited extent, nitric acid with nitrogen dioxide (N_2O_2). If the saturation be complete, every two molecules of nitric oxide become three molecules of nitrogen tetroxide by the aid of one molecule of nitrogen dioxide ($2N_2O_5 + N_2O_2 = 3N_2O_4$). More commonly it is obtained by distilling a mixture of 4 parts of starch and 100 parts of potassium nitrate with 100 parts of sulphuric acid. In this way the nitrogen tetroxide produced is at once taken up in the concentrated nitric acid and an acid of sp. gr. 1.50 is obtainable. This acid is sometimes sold under the name of *fuming nitric acid.*

The ordinary commercial acid has a specific gravity of from 1.30 to 1.41, and is usually prepared by means of chamber sulphuric acid; but if a more concentrated acid is required, a stronger sulphuric acid must be employed. The strongest nitric acid occurring in commerce has a sp. gr. of 1.43, and this is obtained by distilling well dried Chili saltpetre with sulphuric acid having a specific gravity of 1.85.

Nitric acid, so called from nitre, is an extremely sour and corrosive liquid. It was discovered by Raymond Lully, in the thirteenth century, and its constituents by Cavendish, in 1784. When perfectly pure it is colorless; but, as usually obtained, it has a straw color, owing to the presence of hyponitric acid. The concentrated acid, when exposed to the air, emits white fumes, possessing a disagreeable odor. By the action of light it undergoes a slight decomposition, and becomes yellow. It acts powerfully on animal matter, causing its decomposition. On the living tissue it operates as a strong caustic. It stains the skin and most animal substances an indelible yellow color. The compound produced being a nitrogen derivative of protein called *xanthoproteic acid.* On vegetable fiber it acts peculiarly, abstracting hydrogen or water, and oxidizing the remaining elements. When diluted, nitric acid converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to other bodies, which it is enabled to do, as oxygen in the nascent state is liberated in its decomposition. If this liberation takes place while in contact with bodies capable of oxidation, the oxygen goes to effect this oxidation. Free nitric acid, however, will evolve oxygen at a red heat, according to the following reaction:

$$4HNO_3 = 2N_2O_4 + O_2 + 2H_2O$$

It oxidizes sulphur and phosphorus, giving rise to sulphuric and phosphoric acids, and all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. It combines with salifiable bases and forms nitrates. When mixed with hydrochloric acid, mutual decomposition takes place, according to the reaction

$$HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$$

and nitrohydrochloric acid is formed.

Great care must be used in transporting nitric acid, for if the strong acid comes in contact in quantity with vegetable substances like hay, tow, excelsior, paper, etc., fire will be apt to occur. The cause of such accidents was proved by the official inquiry of R. Hass. (*B. Chem. G.*, 1881, 597.)

Nitric oxide or anhydride consists of two atoms of nitrogen and five atoms of oxygen; or, in volumes, of two volumes of nitrogen and five volumes of oxygen, which on combining condense into two volumes of nitric oxide vapor. In 1849 Deville isolated nitric acid oxide or anhydride. The method pursued was to pass perfectly dry chlorine over silver nitrate. The oxide is in the form of colorless brilliant limpid crystals which melt at 29.5° C. and boil at 45° C. In contact with water they form a colorless solution with evolution of heat, without the disengagement of gas.

Assay.—"Proceed as directed under the assay for acids, using 2 cc. of the Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.06302 Gm. of HNO_3." *U. S.*

Uses.—Nitric acid is capable of replacing the hydrochloric acid in the activation of the peptic enzyme and may therefore be used in the treatment of those types of *indigestion* in which hydrochloric acid is of service. It differs from hydrochloric acid in being astringent and is therefore often preferred where there is looseness of the bowels associated with digestive failure. It has also been found of service in chronic *hepatitis,* but is probably inferior to the nitro-hydrochloric acid. For internal use it should be well diluted and taken through a glass tube to avoid injury to the teeth.

Externally, diluted solutions of nitric acid in the proportion of about 12 minims of the stronger acid to a pint of water have been employed as astringent and antiseptic applications to *ulcers.* The most important external use of this acid, however, is as an escharotic. It has been especially employed as combining both caustic and disinfectant properties to *venereal ulcers* and poisoned *wounds,* especially the *bites* of rabid animals. It is also of service for destruction of small tumors, such as *warts;* for this purpose one or two drops of the official nitric acid may be applied by means of a glass rod, repeating in two or three days if necessary. Too deep caustic action may be prevented by washing the part in an alkaline solution as soon as the proper degree of effect has been obtained. In *cancrum oris,* concentrated nitric acid, freely applied, is one of the best local remedies that can be employed for arresting the phagedænic ulceration and disposing the sore to heal, but great care must be exercised to protect the teeth.

Toxicology.—The swallowing of concentrated nitric acid is immediately followed by burning heat in the mouth, esophagus, and stomach, acute pain, disengagement of gas, abundant eructations, nausea, and hiccough. These effects are soon followed by repeated and excessive vomiting of matter having a peculiar odor and taste, tumefaction of the abdomen with exquisite tenderness, a feeling of coldness on the surface, horripilation, icy coldness of the extremities, small depressed pulse, great anxiety, continual tossings and contortions, and extreme thirst. The cases are almost always fatal. Sometimes the collapse has been immediate and has masked all the other symptoms. The best remedies are repeated large doses of alkaline solutions, especially magnesia, or chalk, as antidotes, mucilaginous drinks, olive or almond oil in large doses, emollient fomentations, etc.

Nitric acid is an energetic oxidizing agent and its incompatibilities are usually shown along that line. It decomposes most organic principles when brought in contact with them, sometimes with the production of dangerous explosive compounds, as with the volatile oils, glycerin, etc.

Dose, three to eight minims (0.2–0.5 cc.), largely diluted.

Off. Prep.—Acidum Nitricum Dilutum, *Br.;* Acidum Nitrohydrochloricum, *N. F.;* Acidum Nitrohydrochloricum Dilutum, *N. F., Br.*

ACIDUM NITRICUM DILUTUM. Br.

DILUTED NITRIC ACID

"Diluted Nitric Acid contains 10 per cent. by weight of hydrogen nitrate, HNO_3." *Br.*

"Nitric Acid, 151 grammes; Distilled Water, sufficient to produce 1000 millilitres. Mix." *Br.*

"Specific gravity 1.057. 10 millilitres require for neutralisation 16.8 millilitres of a *N/1 solution of Sodium Hydroxide.* This Diluted Acid is approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898, and contains 10 per cent. by weight of hydrogen nitrate, HNO_3." *Br.*

Dose, from ten to twenty minims (0.6–1.2 cc.).

ACIDUM NITROHYDROCHLORICUM DILUTUM. Br.

DILUTED NITROHYDROCHLORIC ACID

Acidum Nitromuriaticum Dilutum, U. S. P. 1870; Diluted Nitromuriatic Acid; Acide chlorazotique dilué, *Fr.;* Verdünnte Salpetersalzsäure, *G.*

"Nitric Acid, 60 millilitres; Hydrochloric Acid, 80 millilitres; Distilled Water, 500 millilitres. Mix the Acids with the Distilled Water, and keep the mixture in a glass-stoppered bottle for fourteen days before use." *Br.*

The U. S. IX recognized two strengths of this acid but both of them were dismissed at the latest revision, which was, in our judgment, an unfortunate omission. They are, however, recognized by the N. F. (see Part III).

The stronger of these, *Acidum Nitrohydrochloricum,* is the fluid known to the ancients as *aqua regia* from its power of dissolving gold. It differs from the Br. solution not only in being much stronger but in having a very different proportion of the two acids. The diluted nitrohydrochloric acid of the N. F. is decidedly weaker than the British formula.

$$HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$$

Nitrosyl chloride is a ruby-red volatile liquid. In aqueous solution it is decomposed forming nitrous and hydrochloric acids.

It is evident, therefore, that aqua regia is a very complex mixture containing, besides some undecomposed hydrochloric and nitric acids, varying amounts of nitrosyl chloride, free chlorine and nitrous acid, according to the age of the mixture and the conditions under which it has been preserved. The age of the mixture can be approximately gaged by the color. When freshly made it is of a deep golden-yellow verging almost on the orange. The color gradually becomes less and less passing through a lemon-yellow to almost complete colorlessness.

As the peculiar virtues of the mixture probably reside largely in the nitrosyl chloride and free chlorine only solutions of a golden-yellow color should be dispensed; it is preferably made fresh at the time of dispensing.

For an apparatus for making nitrohydrochloric acid upon a large scale, see *P. J.*, xi, 422.

The power of nitrohydrochloric acid to dissolve gold and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in no wise dependent on the compound above referred to, which remains entirely passive during the solution of the metal. When nitrohydrochloric acid is made from too strong acids, there is always a loss of the nitrosyl chloride and of free chlorine by effervescence, in consequence of the acids not containing sufficient water to hold the gaseous products in solution; on the other hand when diluted acids are used the reaction does not take place and no nitrosyl chloride or chlorine are produced.

Properties.—The strong "Nitrohydrochloric Acid is a golden-yellow, fuming, and very corrosive liquid; it has a strong odor of chlorine and is intensely acid to litmus, afterwards bleaching it. It readily dissolves gold leaf." *U. S. IX.*

The diluted acid is pale yellow or colorless. "Specific gravity 1.07. 10 millilitres require for neutralisation about 26.6 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have its chlorine converted into hydrochloric acid by the action of light and the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be kept very long by the apothecary; and care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper or an explosion should occur.

Uses.—Nitrohydrochloric acid, like other mineral acids, is capable of activating pepsin and may be used in cases of *subchlorhydria.* In addition, there is considerable evidence that it increases the flow of bile and is useful in cases of mild *cholangitis* and other conditions in which there is deficiency of this secretion in the intestinal tract. There is reason to believe that its power in increasing the flow of bile is due to a relaxing of the sphincters of the bile duct and permitting the easier emptying of the gall bladder. It has therefore been employed in cases of *cholecystitis* and has even been asserted to be effective in promoting the passage of *biliary calculi.* Formerly it was applied externally either by sponging or in the form of a local or general bath but is at present rarely so used. It has also been lauded as a valuable remedy in *oxaluria.*

The best results are obtained from a freshly prepared acid. It should be given well diluted, after meals, care being exercised to prevent its injuring the teeth. It should never be prescribed in combination with strong alcoholic liquids undiluted, as gases may be generated in sufficient volume to cause explosion. Its incompatibilities are the same as strong nitric acid and strong hydrochloric acid with the added factor of the free chlorine which liberates bromine and iodine from bromides and iodides respectively.

Dose, of the Br. preparation, five to twenty minims (0.3–1.2 cc.)

ACIDUM OLEICUM. U. S., Br.

OLEIC ACID Acid. Oleic.

"Oleic Acid is obtained from fats, and consists chiefly of $C_{17}H_{33}COOH$." *U. S.* "Oleic Acid may be obtained by the saponifying action of alkalies and subsequent action of acids, or by the action of superheated steam upon commercial oleins." *Br.*

Acidum oleinicum, Acidum elainicum; Elaic acid; Acide oléique, *Fr.;* Oleinsäure, Elainsäure, Oelsäure, *G.*

This acid, although known for many years, was not used medicinally until 1872 (*L. L.*, 1872, 709), when John Marshall introduced the oleates to the profession as substitutes for some of the older ointments. (See *Oleata.*)

Preparation.—The difficulty in preparing oleates of good quality arises usually from the use of the commercial oleic acid, which, being obtained as a by-product in the manufacture of glycerin and candles, has a reddish-brown color and a disagreeable fatty odor. It is almost always contaminated with stearic and palmitic acids, with undecomposed glycerides when obtained by the autoclave process, and hydrocarbons when obtained by the distillation of the fat acids. Various processes have been suggested for the purification of oleic acid. Charles Rice (*A. J. P.*, xlv, 2) exposes the commercial acid to a temperature of 4° C., and expresses the liquid portion which is oleic acid deprived of the greater part of the contaminating substances. The odorous and coloring principles are not removed by this process. A writer in *A. J. P.* (xlv, 97) prepares oleic acid for making oleates by saponifying almond oil with potassium hydroxide; decomposing by tartaric acid, separating the precipitated bitartrate, heating for several hours on a water bath with half its weight of finely powdered lead oxide; after cooling, mixing with three times its volume of ether, settling, decanting, and treating the residue with ether as before; agitating the mixed ethereal solution with diluted hydrochloric acid; skimming off the ethereal solution of oleic acid, washing it with water, reskimming, and recovering the ether by distillation. Modifications of this method are described in *U. S. P.*, 20th ed., p. 53. Commercially, oleic acid is now obtainable by the process of decomposition of fatty oils by the action of enzymes. For this purpose, the ferment of the castor oil bean has proven most efficient. Connstein has described the technical application of this process in a paper read at the *International Congress of Applied Chemistry,* held at Berlin in 1903. (Vol. ii, p. 537.) For a paper on the esterification of oleic acid in the presence of a pancreatic ferment, by H. Pottevin, see *P. J.,* 1904, 492.

Low grade oleic acids, obtained by the distillation of wool-grease, etc., may contain cholesterin and other unsaponifiable materials from this source (Allen). Commercial oleic acid is often adulterated with linoleic acid. Hazura claims to be able to show the presence of one per cent. of this by saponifying the mixture and then adding potassium permanganate. (For details see *A. J. P.,* 1889, p. 356.) Grandval and Valser (*Chem. News,* 1890, p. 85) give the following tests for linoleic acid: If a thin layer of the fraudulent oleic acid be placed upon a slip of lead scraped quite clean, and some pure oleic acid be put upon a similar slip of lead for comparison, the next day the impure acid will be more or less resinified, while the pure acid will be scarcely altered. If some drops of oleic acid adulterated with linoleic acid be mixed with an equal volume of soda lye, an intense yellow color will be produced; pure oleic acid, if similarly treated, will merely take a grayish tint.

Description and Physical Properties.—" A pale yellow or brownish-yellow, oily liquid. It has a peculiar lard-like odor and taste, but is free from disagreeable odor. On exposure to air it absorbs oxygen and becomes darker. Oleic Acid is almost insoluble in water, but is miscible with alcohol, chloroform, ether, benzene, petroleum benzin, and with fixed or volatile oils. Specific gravity: about 0.895 at 25° C. On heating strongly, Oleic Acid is decomposed with the formation of acrid vapors.

" When cooled to about 4° C., it congeals to a whitish solid or nearly solid mass. The ash from 5 cc. does not exceed 0.005 Gm. When gradually cooled, Oleic Acid does not become cloudy above 10° C. (*stearic acid*). Shake 5 cc. of Oleic Acid with an equal volume of distilled water, allow the liquids to separate, and filter through a paper filter moistened with water: the filtrate is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*). Boil 1 cc. of Oleic Acid with about 0.5 Gm. of sodium carbonate and 30 cc. of distilled water in a capacious flask: the resulting solution, while hot, is clear or at most opalescent (*neutral fat or mineral oils*).

" Preserve in well-closed glass or stoneware containers, in a cool place." *U. S.*

According to Dieterich, pure oleic acid has the iodine figure 89.8 to 90.05 and commercial oleic acid 65.03 to 86.18.

" A straw-colored liquid, occasionally with a faintly rancid odor. Insoluble in *water,* but readily soluble in *alcohol* (90 per cent.), in *chloroform,* or in *ether.* When cooled it does not become semi-solid until the temperature has fallen below 9° C. Specific gravity 0.890 to 0.910." *Br.*

Oleic acid has been the originating factor in spontaneous combustion of fibers to which it had been applied. The primary cause was attributed to the presence of ferric oxide as a contamination. This acted as a catalyzer. (*J. I. E. C.,* 1918.)

Chemical Constitution.—Oleic acid, $C_{18}H_{34}O_2$, does not belong to the " fatty acid " series, but differs from the corresponding acid of that series, stearic acid, $C_{18}H_{36}O_2$, by having two atoms less of hydrogen. It belongs to a series derived by oxidation from alcohols which, like allyl alcohol, C_3H_5OH, have two atoms of hydrogen less than the normal monatomic alcohols, like propyl alcohol, C_3H_7OH. The alcohol from which oleic acid is in theory derivable is not, however, known. Oleic acid is monobasic, as shown in the formula $HC_{18}H_{33}O_2$. Oleic acid and its compounds are now converted into fatty acid of the higher series, which are solid instead of liquid, by a method known as " hydrogenation " which consists of the application of nascent hydrogen in the presence of metallic nickel which is used as a catalyzing agent. (For further information see under *Olea Fixa.*)

Uses.—Oleic acid is used only in preparing the oleates and in ointments.

Oleic acid is incompatible with alkalies with which it forms soaps, and with oxidizing agents which effect its decomposition.

ACIDUM PHOSPHORICUM. U. S. (Br.)

PHOSPHORIC ACID Acid. Phos.

" Phosphoric Acid contains not less than 85 per cent. and not more than 88 per cent. of H_3PO_4." *U. S.* " Concentrated Phosphoric Acid is a liquid containing 66.3 per cent. by weight of hydrogen orthophosphate, H_3PO_4, and 33.7 per cent. by weight of water. It may be obtained by the oxidation of phosphorus." *Br.*

Acidum Phosphoricum Concentratum, *Br.;* Concentrated Phosphoric Acid; Orthophosphoric Acid; Acide Phosphorique, *Fr.;* Acidum phosphoricum, *P. G.;* Phosphorsäure, *G.;* Acido fosforico, *It., Sp.*

The U. S. P. has very properly abandoned the former official process for this acid; it is more profitably and conveniently made on a large scale, and with such precautions and safeguards as cannot be easily used by the apothecary; the U. S. P. 1880 process will be found upon page 77, U. S. D., 18th edition.

The U. S. X retained the strong acid termed " 85 per cent. phosphoric acid " and the Br. (1914) retained the 66.3 per cent. acid so that the U. S. acid is about 20 per cent. stronger than that of the Br. That of the German Pharmacopœia is only 25 per cent. The glacial phosphoric acid is no longer official, it having been shown that it is practically impossible to obtain it of sufficient purity to be reliable. The present syrupy acid is a great improvement in every way, as it can be obtained of undoubted purity and strength, and by the addition of water, diluted phosphoric acid of any desired strength can easily be produced from it.

The process for its preparation is the well-known one of oxidizing phosphorus by the use of nitric acid, the former British method not differing materially from that of the U. S. Pharmacopœia of 1880, except in the absence of the use of hydrogen sulphide for precipitating the arsenical compounds usually found in phosphorus, and in the greater strength of the finished product.

It has been suggested that red phosphorus might be substituted for common phosphorus, as producing the same results, with less danger of explosion; but the former official process, when carefully followed in reference to due dilution and a moderate heat, is not dangerous. Phosphorus is oxidized at the expense of the nitric acid, any excess of nitric acid and all the lower oxides of nitrogen being driven off by heat. Strong nitric acid acts too energetically on phosphorus, producing explosion and rapid combustion, but when diluted it yields its oxygen slowly, and it is even desirable to aid the operation with a gentle heat. It may also be made by dissolving phosphorus pentachloride or phosphorous oxychloride in hot water.

$$P_2Cl_5 + 4H_2O = H_3PO_4 + 5HCl$$

or

$$POCl_3 + 3H_2O = H_3PO_4 + 3HCl$$

Another method of manufacture is by the use of bone ash and sulphuric acid in molecular proportions.

Much dissatisfaction was at one time caused among pharmacists by the fact that diluted phosphoric acid frequently produces a white precipitate in solutions of ferric salts. An examination proved that this occurred when the glacial acid is used, or when high heat had been employed in the concentration. Experiments conducted by Louis Dohme and Remington indicated that the precipitation resulted from the presence of pyrophosphoric acid. (*Proc. A. Ph. A.*, 1874, 431, 511; 1875, 667.) Considerable difficulty was experienced in driving off all the nitric acid, and in the attempt to do so the temperature became so elevated as to reconvert some of the tribasic acid to the dibasic form. This occurred slightly at 148.8° C., but to a much greater extent between 176.6° C. and 204.4° C. The diluted acid, made from phosphorus, can be brought to the boiling point of 232.2° C. and will then only produce a slight cloud with tincture of ferric chloride, but if diluted, when cool, with about half its bulk of cold water, which causes considerable elevation of temperature, it forms a clear solution. The same acid evaporated, heated to redness, allowed to congeal, and then dissolved in water, precipitated the iron solution. The addition of twenty per cent. of sodium pyrophosphate to the same diluted acid made a preparation which in all respects resembled that made from the glacial acid, thus giving evidence that the presence of this contamination was the cause of the difference in the two preparations.

Description and Physical Properties.—" A colorless, odorless liquid of a syrupy consistence. Phosphoric Acid is miscible with water and with alcohol. When heated, the liquid loses water, and at 200° C. gradually changes to pyrophosphoric acid. At a still higher temperature (about 300° C.) it is converted into metaphosphoric acid, which either volatilizes as dense fumes, or forms, on cooling, a transparent mass of metaphosphoric acid. Specific gravity: about 1.71 at 25° C.

" Phosphoric Acid is strongly acid to litmus paper, even when highly diluted. Phosphoric Acid carefully neutralized with sodium hydroxide T.S. responds to the reactions for phosphates. Render 3 cc. of the dilution alkaline with ammonia T.S., and add magnesium sulphate T.S. (or magnesia mixture T.S.): a white, crystalline precipitate of magnesium-ammonium phosphate is produced. Collect this precipitate, wash it, and then dissolve it in diluted acetic acid: the solution yields a yellow precipitate with silver nitrate T.S. (*distinction from metaphosphoric or pyrophosphoric acid*).

" Phosphoric Acid diluted with 14 volumes of distilled water conforms to the following tests: Warm 5 cc. of the dilution gently, and add 2 cc. of silver nitrate T.S.: the mixture does not become brown (*phosphorous or hypophosphorous acid*). A 10 cc. portion of the dilution meets the requirements of the test for *heavy metals.* A 2 cc. portion of the dilution meets the requirements of the test for *arsenic.* The dilution is not immediately affected by silver nitrate T.S. (*hydrochloric acid*), nor is it affected even after one hour by the addition of an equal volume of tincture of ferric chloride (*pyrophosphoric or metaphosphoric acid*). Mix 1 cc. of the dilution with 6 cc. of distilled water, and add 1 cc. of barium chloride T.S.: no precipitate is produced immediately (*sulphate*). Mix 5 cc. of the dilution with an equal volume of ferrous sulphate T.S., and superimpose the mixture upon 3 cc. of sulphuric acid contained in a test tube: the zone of contact does not assume a brown or brownish-red color (*nitrate*). Transfer 1 cc. of Phosphoric Acid to a graduated cylinder, and add 6 cc. of ether and 2 cc. of alcohol: no turbidity appears (*phosphates*).

" Preserve in glass-stoppered bottles." *U. S.*

Assay.—" Pour about 1 Gm. of Phosphoric Acid into a tared, 100 cc. volumetric flask, weigh accurately, and add enough distilled water to make 100 cc. Transfer 10 cc. of this solution to a 100 cc. volumetric flask, add a drop of phenolphthalein T.S., and neutralize the mixture with special sodium hydroxide T.S. Add 50 cc. of tenth-normal silver nitrate from a burette while gently shaking. Mix a small amount of reagent zinc oxide with distilled water and gradually add the mixture, in small portions, until the liquid is neutral to litmus paper. Now add distilled water to make the liquid measure 100 cc., mix well, and filter through a dry filter, rejecting the first 5 cc. Transfer 50 cc. of the filtrate with a pipette to a flask, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and determine the excess of silver nitrate by titration with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate corresponds to 0.003269 Gm. of H_3PO_4." *U. S.*

"A colorless, syrupy liquid with an acid taste and reaction. Leaves, on evaporation, a residue which melts at a low red heat, and when cold forms a glass-like mass. Yields, when neutralised, the *reactions* characteristic of phosphates. Specific gravity 1.5. 1 gramme mixed with a solution of 5 grammes of *sodium chloride* in 20 millilitres of *water* requires for neutralisation 13.5 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields when diluted with *water* no characteristic *reactions* for copper, calcium, chlorides, or nitrates, and not more than slight *reactions* for iron or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—This acid is used in making phosphates and lactophosphates. It has the same medicinal properties and uses as the diluted phosphoric acid making allowance for the difference in strength but is practically never prescribed.

Off. Prep.—Acidum Phosphoricum Dilutum, *U. S., Br.;* Liquor Phosphatum Acidus, *N. F.;* Liquor Phosphatum Compositus, *N. F.*

ACIDUM PHOSPHORICUM GLACIALE.—(*Glacial Phosphoric Acid; Metaphosphoric Acid; Monobasic Phosphoric Acid; Monohydrated Phosphoric Acid; Acide phosphorique glaciale,* Fr.; *Glasige Phosphorsaure,* G.) Formula HPO_3; mol. wt. 79.41.—Phosphoric oxide consists of two atoms of phosphorus and five atoms of oxygen, P_2O_5, and can be obtained only by the direct union of its constituents, which takes place when phosphorus is burned in perfectly dry oxygen gas. Thus procured, it is in the form of a white amorphous powder, extremely deliquescent, volatilizable at a red heat, and assuming, when it cools after fusion, a vitreous appearance. The classic researches of Graham first established clearly the character of the several varieties of phosphoric acid, which may be considered as derived from this oxide.

When amorphous phosphorus is boiled with nitric acid, or when phosphoric oxide is boiled with water, the oxide takes up three molecules of water, and yields tribasic or *ordinary phosphoric* acid according to the reaction:

$$P_2O_5 + 3H_2O = H_6P_2O_8 \text{ or } (H_3PO_4)_2$$

If this acid be heated for a considerable time to 215° C., the two molecules lose one molecule of water and yield *pyrophosphoric acid,* a tetrabasic variety, according to the reaction:

$$H_6P_2O_8 - H_2O = H_4P_2O_7$$

Lastly, at a red heat the ordinary phosphoric acid is converted into *metaphosphoric acid,* a monobasic variety, according to the reaction:

$$H_3PO_4 - H_2O = HPO_3$$

This last variety may also be obtained direct from the oxide by dissolving it in cold water, when it takes up one molecule of water:

$$P_2O_5 + H_2O = H_2P_2O_6 \text{ or } (HPO_3)_2$$

An aqueous solution of either of the two acids of higher basicity, heated so long as water escapes, yields the metaphosphoric acid; and as, upon cooling, it becomes a transparent ice-like solid, it has received in this state the name of glacial phosphoric acid. Conversely, this monobasic acid is slowly transformed, in aqueous solution, and more rapidly if the solution is heated, into the tribasic form. John M. Maisch ascertained that nitric acid, added to the solution of the monobasic acid, with the aid of heat, caused the change from the monobasic to the tribasic form, *i.e.,* to the common phosphoric acid, without the intermediate production of the tetrabasic variety. *Pyrophosphorous acid,* $H_4P_2O_5$, has been obtained by V. Auger in the form of colorless needles, melting at 38° C. (*C. R. A. S.,* cxxxvi, 814.)

The three forms of phosphoric acid are distinguishable by peculiar reactions. Thus, the monobasic is characterized by coagulating albumin, and giving white, gelatinous, uncrystallizable precipitates with the soluble salts of barium, lime, and silver; the tetrabasic does not coagulate albumin, and, though it causes a white precipitate with silver nitrate, must first be neutralized; the tribasic does not coagulate albumin, and, until neutralized, does not precipitate silver nitrate, but after neutralization throws down a yellow precipitate of silver phosphate.

Glacial phosphoric acid is most advantageously obtained from calcined bones, by first treating them with sulphuric acid, which produces an insoluble calcium sulphate and soluble acid phosphate; then dissolving out the latter salt, and saturating it with ammonium carbonate, which generates ammonium phosphate in solution; and, finally, obtaining the ammonium phosphate by evaporation to dryness, and then igniting it in a platinum crucible. The ammonia and all the water except the one molecule needed for the formation of metaphosphoric acid are driven off, and the glacial acid remains.

Properties.—Glacial phosphoric acid is in the form of a white, uncrystallizable, fusible solid; inodorous, very sour to the taste, slowly deliquescent, slowly soluble in water, and soluble also in alcohol. Its formula is HPO_3, and it is made up of 11.2 per cent. of water in combination with 88.8 per cent. of phosphoric oxide.

Impurities.—Glacial phosphoric acid is very little used at the present time. For further information concerning its adulterations, etc. See *U. S. D.*, 20th ed., p. 58.

ACIDUM PHOSPHORICUM DILUTUM. U. S., Br.

DILUTED PHOSPHORIC ACID Acid. Phos. Dil.

"Diluted Phosphoric Acid is an aqueous solution containing not less than 9.5 per cent. and not more than 10.5 per cent of H_3PO_4." *U. S.* "Diluted Phosphoric Acid contains 10 per cent. by weight of hydrogen orthophosphate, H_3PO_4." *Br.*

Acide phosphorique médicinale, *Fr.*: Verdünnte Phosphorsäure, *G.*

"Phosphoric Acid, 116 Gm.; Distilled Water, 884 Gm.; to make 1000 Gm. Mix them." *U. S.* "Concentrated Phosphoric Acid, 159.5 grammes; Distilled Water sufficient to produce 1000.0 millilitres. Mix." *Br.*

Properties.—Diluted phosphoric acid is a colorless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties, although when evaporated so as to become dense, it is not corrosive like the other mineral acids. Neubauer found that the strong acid, when pure and warm, was capable of dissolving calcium oxalate.

Description and Physical Properties.—"A clear, colorless, odorless liquid. Specific gravity: about 1.057 at 25° C.

"Diluted Phosphoric Acid is strongly acid to litmus paper. Evaporate 20 cc. of Diluted Phosphoric Acid on a water bath to a volume of 4 cc. Cool, transfer 2 cc. to a graduated cylinder, and add 6 cc. of ether and 2 cc. of alcohol: no turbidity appears (*phosphate*). Diluted Phosphoric Acid conforms to the other tests for identity and purity under *Acidum Phosphoricum.*

"Preserve in well-stoppered bottles.

"**Assay.**—Pour about 1 Gm. of Diluted Phosphoric Acid into a tared, 100 cc. volumetric flask, weigh accurately, add a drop of phenolphthalein T.S., and neutralize the mixture with special sodium hydroxide T.S. Add 50 cc. of tenth-normal silver nitrate, and proceed as directed in the assay under *Acidum Phosphoricum.* Each cc. of tenth-normal silver nitrate corresponds to 0.003269 Gm. of H_3PO_4." *U. S.*

"Specific gravity 1.057. 10 millilitres mixed with a solution of 5 grammes of *sodium chloride* in 20 millilitres of *water* require for neutralisation 21.6 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator." *Br.*

Bauzil suggests the assay of phosphates by precipitation with magnesia mixture and titration of the suspended precipitate with tenth-normal hydrochloric acid. He also gives minute directions for assaying for phosphates in urine. (*J. P. C.*, 1917, p. 321.)

Phosphorous acid may be detected by testing the medicinal acid with a solution of corrosive sublimate, which will be converted into calomel if this impurity be present.

Old diluted phosphoric acid is very apt to contain microscopic plants. The presence of traces of hydrochloric acid is said to prevent their formation. (Rother, D. C., 1886, p. 99; L. E. Sayre, *Proc. A. Ph. A.*, 1885.)

Uses.—Diluted phosphoric acid, like other mineral acids, is capable of replacing the hydrochloric acid in peptic digestion and is a useful drug, therefore, in certain types of *dyspepsia.* It is doubtful, however, whether it possesses any advantage over diluted hydrochloric acid.

It has been shown that the utilization of calcium by the body is dependent upon an ample supply of phosphates and consequently, phosphoric acid and its salts may be useful in various diseases of the bone in which there is a deficiency of lime deposition. It may, perhaps, have a similar value in certain nervous diseases when there is calcium deficiency. Schmitz (*B. K. W.*, 1922, l, 432) has found, from experiments on soldiers and mine-workers, that the salts of phosphoric acid increase muscular vigor.

The neutrality of the blood is maintained in part by the "buffer" action of the phosphates; when there is an abundance of base the phosphoric acid exists in the blood as a neutral salt, but if, for any reason there is an increased formation of acid in the body, the blood yields a part of the base from its phosphate the excess of phosphoric acid being excreted by the kidney. For this reason phosphoric acid affords one of the least injurious means of increasing the acidity of the urine and it has therefore been used in the treatment of *phosphatic deposits* and certain types of *cystitis.* Generally, however, the monobasic sodium phosphate is preferred for this purpose to the acid itself. (See *Sodii Phosphas Acidum*).

Diluted phosphoric acid is incompatible with salts of silver, lead, and mercury, and also with many compounds of iron, aluminum and calcium, insoluble precipitates being formed unless the acid be much in excess in which case the precipitate may redissolve.

Dose, from fifteen to sixty minims (0.9–3.75 cc.) well diluted.

ACIDUM SALICYLICUM. U. S., Br.

SALICYLIC ACID Acid. Salicyl.

"Salicylic Acid, dried at 100° C. for two hours, contains not less than 99.5 per cent. of $C_6H_4(OH).COOH$ 1:2." *U. S.* "Salicylic Acid, $HC_7H_5O_3$, may be obtained from natural salicylates such as the oils of winter-green (Gaultheria procumbens, *Linn.*) and sweet-birch

(Betula lenta, *Linn.*), or by the interaction of sodium phenate and carbon dioxide." *Br.*

Ortho-oxybenzoic Acid; Acidum Spiricum; Acidum oxybenzoicum; Acide Salicylique, *Fr.;* Acidum salicylicum, *P. G.;* Salicylsäure, Spirsäure, Salicoylsäure, Spiroylsäure, *G.;* Acido salicilico, *It., Sp.*

In 1834 *salicyl aldehyde* (so-called *salicylous acid*) was discovered by Pagenstecker in the flowers of *Spiræa Ulmaria,* L. In 1837, Piria and Ettling found that by oxidizing agents salicyl aldehyde was converted into a new body, salicylic acid, and in 1839, Löwig and Weidmann derived the latter principle directly from the flowers of the *Spiræa Ulmaria* L. Shortly afterwards Procter (*A. J. P.*, 1843; Aug., 1875) discovered that the acid could be procured from the oil of wintergreen (*Gaultheria procumbens* L.), which is now known to contain over 98 per cent. of methyl salicylate. Methyl salicylate is indeed obtainable by distillation from very many plants, but the probabilities are that it never exists already formed in the plant, but is produced during the process of distillation. (See *Oleum Gaultheriæ.*) When potassium hydroxide is added to methyl salicylate, potassium salicylate is formed, and methyl alcohol is also produced. If this latter be volatilized by heating, the acid is readily obtained by means of hydrochloric acid. Notwithstanding the discovery of this fact, and also the invention of still another process of manufacture by Ettling in 1845, salicylic acid remained so expensive as to be of no value in the arts until Kolbe and Lautemann discovered that it could be prepared by uniting phenol with carbon dioxide through the instrumentality of sodium. The article now began to attract some attention, but remained beyond the reach of general use until Kolbe, by continuing his researches, succeeded, in 1874, in producing it at a moderate cost. Traphagen and Burke found salicylic acid to be a natural constitutent of many fruits, as follows: strawberries, raspberries, blackberries, currants, plums, black cherries, apricots, peaches, grapes, crab apples, apples, and oranges. (*J. Am. C. S.*, 1903, 242.) In none of these, however, can it be detected by the ordinary tests in the proportions in which these substances are used in testing for the presence of salicylic acid which may have been used as a preservative.

Preparation.—While salicylic acid may be prepared from salicin by fusion with potassium hydroxide, or from oil of wintergreen by saponification with potassium hydroxide solution, practically it is usually obtained, according to Kolbe's patent, by treating sodium phenate (or carbolate) with carbon dioxide gas. For this purpose, the most concentrated caustic soda solution is evaporated with the corresponding amount of phenol to a dry powder, which is then heated to 100° C., while a stream of dry carbon dioxide gas is passed over it. The temperature is gradually raised to 180° C., increased to 220° C. as soon as phenol distils over, and finally raised to 250° C., until no more phenol distils. In the retort, the half of the phenol used remains as basic sodium salicylate, while the other half has distilled over unchanged. The reaction is as follows:

$$2C_6H_5ONa + CO_2 = C_6H_5OH + C_6H_4(ONa)COONa$$

The sodium salt thus obtained is dissolved in water, decomposed by hydrochloric acid, the salicylic acid filtered off, washed, and crystallized out of hot water, or purified by sublimation in a current of superheated steam. P. W. Hofmann subsequently patented a process whereby distillation with superheated steam, with its attendant loss, is obviated; to the crude solution is added stannous chloride, which precipitates a dark mass containing the impurities, the clear supernatant liquid is then decomposed with hydrochloric acid and the crystals of salicylic acid purified by washing and the use of centrifugals. (*Ph. Centralh.*, 1892, 412.) An important improvement was subsequently made in Kolbe's process whereby all, instead of only half, of the phenol-sodium is converted into salicylate. R. Schmitt has found (Wagner's *Jahresbericht für Chem. Tech.*, 1885, p. 490) that if dry sodium phenolate and dry carbon dioxide are allowed to act on each other at ordinary temperatures, as long as absorption takes place a phenyl-sodium carbonate, $CO\left\{\begin{matrix}OC_6H_5\\ONa\end{matrix}\right.$, is formed. If this is heated for several hours in a closed vessel to 140° C., a molecular rearrangement takes place, and simple sodium salicylate, $C_6H_4(OH)COONa$, is formed without any separation whatever of phenol.

Lloyd's process for preparing salicylic acid from oil of wintergreen is as follows: Pure wintergreen oil, 3 parts; white potassium hydroxide, 3 parts; hydrochloric acid, 8 parts; water, q. s. Dissolve the potassium hydroxide in two parts of water in a glass or porcelain vessel, and heat to the temperature of 82.2° C. Stir into this gradually the oil, using a glass or porcelain spatula. Into another vessel place 64 parts of cold distilled water, and add the hydrochloric acid. Then with constant stirring add the solution of the potassium salicylate. The magma of minute crystals of salicylic acid must be separated with a thin muslin strainer (previously moistened) and pressed, then dried by exposure to a temperature of 65.5° C. Dissolve this crude acid in six parts of cold alcohol, filter through a funnel stopped with cotton and, with constant stirring, pour the filtrate into 32 parts of cold water. The purified crystals may be separated by straining through muslin, and dried by exposure to a heat of 65.5° C. The yield is a trifle less than 2 parts. For Walter's process, see *Bull. Pharm.*, 1899, 54.

Salicylic acid has also been obtained synthetically from copper benzoate and water, which, when heated together in sealed tubes, yield cuprous oxide, free benzoic acid, and salicylic acid. (E. F. Smith, *Am. Chem. J.*, ii, p. 338). A. Rautert has found that the acid volatilizes with steam of 170° C., and has devised a process of purification based upon this, which yields at very little cost a beautiful product. Biel (*Ph. Z. R.*, 1876) reports that the sublimed acid is liable to decompose spontaneously. Dialyzed salicylic acid of beautiful appearance has been in the market since 1876. All traces of tarry matter can be removed by dialysis, and this acid is unexceptionable. Kolbe also obtained salicylic acid from barium and calcium carbolates, but the yield was less than when sodium salt was employed. Potassium phenol yielded only a trace of salicylic acid, but an abundance of *paraoxybenzoic* acid.

Description and Physical Properties.—" Fine needles, or a bulky crystalline powder. It has a sweetish, afterwards acrid taste, and is stable in the air. Synthetic Salicylic Acid is white and odorless. When prepared from natural methyl salicylate, the Acid may have a slightly yellow or pink tint, and a faint, gaultheria-like odor. One Gm. of Salicylic Acid is soluble in 460 cc. of water, 2.7 cc. of alcohol, 42 cc. of chloroform, 3 cc. of ether, 3 cc. of acetone, 135 cc. of benzene, and in 52 cc. of oil of turpentine, at 25° C. One Gm. is soluble in about 15 cc. of boiling water.

" Salicylic Acid melts between 157° and 159° C. Salicylic Acid responds to the reactions for salicylates, page .

" Ash: not more than 0.05 per cent. Allow a solution of 1 Gm. of Salicylic Acid in 3 cc. of alcohol to evaporate spontaneously in a glass or porcelain dish, protected from dust: the synthetic Acid yields a white, crystalline residue, while the Acid prepared from natural methyl salicylate yields a white, or not more than a slightly yellow, or a slightly pink residue (*coloring matter*). Dissolve 1 Gm. of Salicylic Acid in an excess of cold sodium carbonate T.S., agitate the liquid with an equal volume of ether, separate the ether layer, and allow it to evaporate spontaneously: the residue, if any, is free from the odor of phenol. A solution of 0.5 Gm. of the synthetic Salicylic Acid in 10 cc. of sulphuric acid acquires not more than a light yellow color. The Acid prepared from natural methyl salicylate under similar conditions may produce a slightly brown color (*readily carbonizable substances*). Dissolve 0.5 Gm. of Salicylic Acid in 10 cc. of alcohol containing a few drops of nitric acid: the solution is unaffected by the addition of a few drops of silver nitrate T.S. (*chloride*).

" **Assay.**—Dissolve about 0.5 Gm. of Salicylic Acid, previously dried at 100° C. for two hours and accurately weighed, in 25 cc. of diluted alcohol, which previously has been neutralized with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator. Titrate the solution with tenth-normal barium hydroxide until the pink color is restored. Each cc. of tenth-normal barium hydroxide corresponds to 0.01381 Gm. of $C_6H_4(OH).COOH$." *U. S.*

" Distinct, prismatic, colorless crystals. Taste at first sweetish, then acid, leaving a burning sensation in the throat. Soluble in about 500 parts of *water*, in 3.5 of *alcohol* (90 per cent.), or in 2 of *ether*. Melting point 156° to 157° C. Carefully heated it volatilises without decomposition. Dissolves in *solution of ammonium acetate*, and in *solution of sodium phosphate*. *T. Sol. of ferric chloride* gives with the aqueous solution a violet color, or, if the solution be largely diluted, a reddish-violet color. Shaken with a small proportion of water, the mixture filtered, and the solution evaporated, there remains a white residue, having no buff-tinted fringe (absence of iron, organic impurities, and coloring matter). Salicylic Acid dissolves in cold *sulphuric acid*, imparting to the liquid not more than a faint brownish tint in fifteen minutes (absence of certain organic impurities). When 1 gramme of the Acid is dissolved in an excess of cold *solution of sodium carbonate*, the liquid shaken with an equal volume of *ether*, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, is free from the odor of phenol (absence of phenol). *Arsenic limit* 2 parts per million. No appreciable ash." *Br.*

When heated rapidly it is converted into phenol and carbon dioxide. Although salicylic acid requires 500 parts of water for its solution at 20° C. it is stated that, by careful heating, glycerin can be made to dissolve 1 part in 50, and that the solution not only remains clear on cooling, but also may be diluted with water without separating. Goldsborough affirms that a mixture of the acid with alcohol, 1 to 10, may be diluted with 150 parts of water without crystallizing. By the presence of various neutral salts its solubility is increased without its antiseptic value being interfered with. It dissolves when mixed with 1 part of potassium nitrate, in 50 parts water; 1½ parts of ammonium citrate, in 60 parts water; 2 parts sodium sulphite, in 50 parts water; 2 parts sodium phosphate, in 50 parts water; 2½ parts sodium phosphate, in 12½ parts water. (See Allen, *Com. Org. Anal.*; also Rother, *A. J. P.*, 1886, p. 420.) The solubility of salicylic acid in fixed oils is very slight with the exception of castor oil with which a solution containing as much as 15 per cent. can be made.

On distilling salicylic acid or one of its salts with methyl alcohol and sulphuric acid, acid methyl salicylate is formed, having an agreeable aromatic odor. The reaction with ferric salts is much more delicate (1 in 100,000) than that of phenol with the same reagent (1 in 3000). Commercial salicylic acid was formerly very impure. Sodium chloride, phenol, cresotic acid, and oxybenzoic and paraoxybenzoic acids were the usual impurities. These may be detected by the official tests.

The most sensitive test for it is a ferric salt, with which it develops a beautiful violet color. Goldsborough states that to insure the delicacy of this reaction it is necessary that the iron salt be perfectly neutral; also that with this precaution he has clearly detected 1 part of the acid in 400,000 parts of water. On the addition of ammonia the violet color is changed to a reddish-brown, then to an orange, then to a permanent greenish-yellow. Sulphuric and nitric acids change the violet to a light brown (Goldsborough). It must be remembered that *salicylous acid* (salicylic aldehyde, C_6H_4OHCHO) reacts similarly with ferric salts. Salicylous acid, however, precipitates the silver potassio- or ammonio-nitrate white, the salicylic acid yellow. A. Fagans (*A. J. P.*, 1893, p. 133) points out that salicylic acid cannot be colorimetrically estimated in aqueous solutions in presence of phenols, but that in alcoholic solution only the former reacts with ferric chloride. M. Claasz (*A. Pharm.*, 1915, p. 360) has made an exhaustive study of the *iron salicylates* and has prepared the following varieties: *Ferrous disalicylate,* colorless crystals; *ferrous cresstinate,* white salt; *ferrous para-oxybenzoate* colorless crystals; *ferrous methoxy salicylate,* yellowish crystals; basic *ferrous salicylate,* yellowish green crystals; ferric disalicylate, a black mass; ferric ferri-salicylate, blackish crystals; basic ferric ferri-salicylate, rust colored crystalline powder; dibrom-compound of ferric ferri-salicylate violet powder; ferrous ferro-salicylate, yellow crystals. He states that the purple compound which is so characteristic of the identifying test for salicylic acid is a tetra-chlor compound of ferric ferri-salicylate.

By distilling with alcohol and strong sulphuric acid, salicylic acid forms methyl- and ethyl-salicylic acids.

Uses.—Salicylic acid is an active disinfectant distinctly superior to phenol in its antiseptic properties and probably also in its germicidal effects. De LaCroix (*A. E. P. P.*, 1881, xiii) found that in the proportion of one part in a thousand it was sufficient to prevent the growth of various bacteria, and Kolbe has shown that as little as 0.04 per cent. is sufficent to retard souring of milk. In the experiments of H. C. Wood, Jr. (*U. P. M. B.*, February, 1907), 0.5 per cent. killed the colon bacillus in five minutes' exposure, and De LaCroix found that one in four hundred was germicidal after one and one-half days' exposure. Like many other disinfectants it retards, and if in sufficient concentration arrests, enzymic fermentation. Locally salicylic acid is strongly irritant to mucous membranes and its irritant action can be demonstrated upon the skin. It has the peculiar property of softening and finally causing the separation of the horny matter of the epiderm.

In ordinary quantities when taken internally the salicylates exercise practically no effect upon the circulation nor respiration. It appears to act upon the central nervous system somewhat like the anilin derivatives, lessening painful sensation and also causing reduction in febrile temperature; in both of these actions, however, it is inferior in power to the coal-tar antipyretics. After full doses of salicylates there is a marked increase in the elimination of uric acid and in some cases also of other nitrogenous waste products. This seems to be due to increased activity of the kidney and not to hastened catabolism. This view is strongly indicated by the observations of Fine and Chase (*J. Bi. Chem.*, 1915, xxi, 371) that the uric acid of the blood is diminished, and by the studies of Hanzlik and Scott (*A. I. M.*, 1917, xix and xx) which have shown that large doses of salicylates have a markedly irritating effect upon the kidney—shown in human beings by the appearance of albumin and casts in the urine and a diminished ability to excrete phenolsulphonphthalein and confirmed in the lower animals by pathological evidence of nephritis.

Whether administered in the form of the acid itself or as one of its salts salicylic acid circulates in the blood almost entirely in the form of sodium salicylate. It was formerly believed that most of it united with glycocoll and appeared in the urine in the form of a new compound known as salicyluric acid but Hanzlik (*J. P. Ex. T.*, 1917, x, 461) maintains that this opinion was founded on improper chemical methods and that no salicyluric acid can be demonstrated in the urine. The urine often shows a greenish tinge from a small amount the salicylate being changed to pyrocatechin. According to Hanzlik and Wetzel (*J. P. Ex. T.*, 1919, xiv, 25) over 80 per cent. of the salicylic acid administered can be recovered as a salicylate from the urine in normal men. In diseased conditions accompanied with a heightened catabolism, such as fever and hyperthyroidism, the larger portion is destroyed in the body.

After large doses salicylic acid causes symptoms resembling those seen after quinine; there is fulness of the head, roaring in the ears often with headache and sometimes disturbances of hearing and vision. Nausea and vomiting—due to an action upon the emetic center—are also frequent symptoms of large doses. With toxic quantities these symptoms are intensified and there is usually a fall in the bodily temperature with profuse sweating, excessive restlessness passing into delirium, a slow pulse, with at first hurried and later depressed respiration.

Salicylic acid is used both for its local effect and its systemic action. Because of its relative insolubility in water it is rarely of service as a direct surgical germicide but *salicylated cotton* and gauze are widely used. This may be prepared by dissolving two ounces (62 Gm.) of salicylic acid in two pints (1 liter) of alcohol, diluting with twenty pints (9.5 liters) of water and saturating with this six and one-half pounds (2–4 kilogm.) of absorbent cotton, and drying. Wadding so prepared contains about 2.53 per cent. of salicylic acid. It is also widely used in the form of lotions and ointments in the treatment of various *skin diseases,* especially chronic *eczemas.* Its beneficial action in these conditions is due in part to its antiseptic effect and in part to its softening action upon the corneous layer of the skin. Because of this latter property it is also widely employed for the purpose of removing *corns.* Weinbrenner (*M. M. W.,* lxi) has obtained good results from the local application of crystalline salicylic acid to superficial *cancers* of the skin.

Internally salicylic acid and its salts are used as urinary antiseptics, analgesics, antipyretics, and in the treatment of various forms of rheumatism. As the neutral salicylates are almost without antiseptic influence and as salicylic acid in whatever form exhibited circulates in the blood only in combination with a base, it is evident that any antiseptic action in the urine must depend upon the decomposition of its salt by urinary acids with the liberation of free salicylic acid; therefore it is of service as a urinary antiseptic only when the urine is acid in reaction. As an analgesic or antipyretic it has the same range of usefulness as the aniline derivatives, but except in rheumatic conditions is distinctly inferior to them.

The most important use of the salicylates is in the treatment of various rheumatic conditions. There are two distinct groups of conditions to which the term *rheumatism* is applied. One of these groups, which includes *acute articular rheumatism* and *tonsillitis,* is of infectious origin; in the other group, are included various painful conditions of the muscles, nerves, or joints, occurring in persons of a *lithemic diathesis.* The cause of this latter group of disturbances is unknown. There has been a great deal of difference of opinion as to the mode of action and precise value of the salicylates in rheumatism. Some have maintained that the relief seen after their use was purely symptomatic and to be attributed entirely to the analgesic and antipyretic effects of the drug, while others have maintained that the action is truly curative and probably due to a direct influence upon the causative agent. Against the former view are the positive opinions of practitioners of wide experience based upon clinical observations and the failure of other analgesics, such as acetphenetedin, to produce similar effects; while against the theory of specificity stands the opinion of almost equally experienced clinicians and the failure of any acceptable explanation of its mode of action. Formerly the benefit of the salicylates in rheumatism was attributed to their power to increase the elimination of uric acid but as our present theories regard this as a result rather than a cause, at least in rheumatic fever, the explanation no longer suffices. Rheumatic fever to-day is commonly viewed as an infectious disease and some have attempted to ascribe the value of the salicylates to their antibacterial powers. Against this view, however, it has been urged that although the salicylic acid is a powerful germicide the neutral salts are but very feebly disinfectant and because of the alkalinity of the system the salicyl radical must circulate only in combination with a base. The theory, suggested in previous editions of this work, that there might be a local liberation of free acid in the inflamed joints due to a local excess of carbon dioxide, seems to be disproven by the observations of Boots and Cullen (*Proc. of the Soc. for Exp. Biol.,* 1912., xix, 287) who showed that the joint exudates in rheumatic fever are alkaline, and the observations of Hanzlik (*J. P. Ex. T.,* 1921, xvii, 385) who has found that in fatal asphyxiation the hydrogen ion concentration of the blood is still too low to liberate free salicylic acid. It is of course within the realms of possibility that the specific germs responsible for rheumatic fever may have a peculiar susceptibility to the salicylates. While no direct evidence of such a view has been brought forward it is not uncommon to find substances of relatively low disinfectant powers very poisonous to one or two species of bacteria. Closely allied to rheumatic fever, and probably due to the same micro-organism, are certain types of *acute tonsillitis* and some cases of *chorea;* in these conditions the salicylates are often of great service, although their action is neither so certain nor so prompt as in the case of joint involvement. It is probable also that there is a type of *chronic arthritis* which is caused by the germ of rheumatic fever. Perhaps also certain inflammations of serous membranes, as *iritis,* may be due to the same cause. In this latter group of diseases the salicylates are often of service.

In *lumbago, pleurodynia* and other myalgias, in certain inflammations of nerves as *sciatica,* in some cases of *chronic arthritis,* and the host of similar conditions which for lack of better diagnostic acumen we are wont to call *rheumatism,* salicylic acid is a valuable palliative and often appears to exercise even a curative effect.

Moulton (*J. A. M. A.,* 1920, lxxv, 725) recommends the salicylates in the treatment of sympathetic *ophthalmia* occurring after injuries to the other eye. According to Hanzlik (*A. J. M.,* 1917, xix, and 1918, xx) full therapeutic doses of salicylates have an injurious effect upon the kidneys, as shown by albuminuria, diminished excretory power of the kidney, and even the appearance of œdema.

There has been a great deal of discussion concerning the relative value and toxicity of salicylic acid obtained from plants and that manufactured from phenol. There is a widespread belief among clinicians that the so-called "natural salicylates" are superior in power and less prone to cause unpleasant symptoms than those manufactured synthetically. The toxic properties of the synthetic salicylates have been attributed to various phenol bodies, especially *cresotinic acid,* which are present as impurities, but Stockmann (*J. P. Ex. T.,* 1912, iv) has shown that these substances are scarcely more actively poisonous than salicylic acid and are possessed of similar curative properties in rheumatism. In an elaborate investigation undertaken under the auspices of the Council of Pharmacy and Chemistry of the American Medical Association, which included an historical, chemical, pharmacological, and clinical investigation of this subject, the conclusion was reached that there was no trustworthy evidence of any kind that the natural salicylates were superior to those prepared from phenol. (See *J. A. M. A.,* 1913, lx and lxi.)

Salicylic acid itself is so irritant to the stomach that it is rarely used internally. Because the neutral salicylates are so much less powerfully antiseptic some have believed that the salicylic acid is theoretically preferable in those cases where an antiseptic influence is desired as in *cystitis* and *rheumatic fever,* but as the acid must immediately combine with the excess of alkali in the blood, this theory is erroneous. There is no justification for the internal use of the free acid.

The use of salicylic acid or its salts as preservatives of beer, or milk, or other articles of food, is to be strongly condemned and its use is prohibited under the Federal and most state food and drugs acts.

Salicylic acid is incompatible with compounds of lead, silver, mercury, bismuth, zinc, and some other metals with which it produces insoluble precipitates. With ferric salts it produces the well-known violet color which is used as a test for its identity. Oxidizing agents destroy its identity and produce various derivatives. It is frequently thrown out of solution when the salicylates are prescribed with either organic or inorganic acids which set it free.

Dose, five to twenty grains (0.32–1.3 Gm.).

ACIDUM STEARICUM. U. S.

STEARIC ACID Acid. Stear.

"Stearic Acid is obtained from tallow and other solid fats, and consists chiefly of $C_{17}H_{35}$.-COOH." *U. S.*

Acidum Stearinicum; Acide Stéarique, *Fr.;* Talgsäure, Stearinsäure, *G.*

Preparation.—Stearic acid is obtained from tallow soap by treating it with sulphuric or hydrochloric acid, whereby sodium sulphate or chloride is produced and stearic acid liberated; it is also made on a large scale by purifying the residue left after making glycerin by acting on stearin with superheated steam. (See *Glycerinum.*)

Properties.—A hard, white or faintly-yellowish, somewhat glossy and crystalline solid. It is odorless, or has a slight, tallow-like odor, and is stable in the air. Stearic Acid is almost insoluble in water. One Gm. dissolves in 21 cc. of alcohol, 2 cc. of chloroform, and in 3 cc. of ether, at 25° C. It is freely soluble in carbon disulphide and in carbon tetrachloride.

"Melting point: not below 56° C. Congealing point: not below 54° C. Ash: not more than 0.1 per cent. Boil 1 Gm. of Stearic Acid and 0.5 Gm. of sodium carbonate with 30 cc. of distilled water in a capacious flask: the resulting solution while hot is not more than opalescent (*neutral fat or paraffin*). Shake melted Stearic Acid with an equal volume of hot distilled water, cool, and filter: the filtrate is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*)." *U. S.*

The melting point, 56° C., is an important factor in testing stearic acid, as a lower melting point would unfit it for use in making glycerin suppositories.

Uses.—This acid was introduced into the U. S. P. solely because of its use in making glycerin suppositories. Stearic acid combines with alkalies to form the corresponding salts and is decomposed by oxidizing agents.

Off. Prep.—Suppositoria Glycerini, *U. S.;* Linimentum Saponati Camphoratum, *N. F.*

ACIDUM SULPHURICUM. U. S., Br.

SULPHURIC ACID Acid. Sulphuric.

"Sulphuric Acid contains not less than 93 per cent. and not more than 95 per cent. of H_2SO_4." *U. S.* "Sulphuric Acid may be obtained by the combustion of sulphur or pyrites and the oxidation and hydration of the resulting sulphur dioxide by means of nitrous and aqueous vapours, and contains not less than 95 per cent. by weight of hydrogen sulphate, H_2SO_4." *Br.*

Oil of Vitriol, Vitriolic Acid; Hydrogen Sulphate; Acide sulfurique; Huile de Vitriol, *Fr.;* Acidum Sulfuricum, *P. G.;* Vitriolöl, Schwefelsäure, *G.;* Acido solforico, *It.;* Acido sulfurico, *Sp.*

Preparation.—Sulphuric acid is obtained by burning sulphur or iron pyrites, FeS_2, and allowing the product of combustion, SO_2, to mix with nitrous fumes obtained from the decomposition of sodium nitrate, which change SO_2 into SO_3, and this uniting with steam yields H_2SO_4. If the sulphur were burned by itself, the product would be sulphurous oxide, which contains only two-thirds as much oxygen as sulphuric oxide. The object of the sodium nitrate is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to remember that several oxides of nitrogen have oxidizing power. Thus, the main reactions of the sulphuric acid process are

$$2SO_2 + N_2O_3 + O_2 + H_2O = 2SO_2OH.NO_2$$
$$2SO_2OH.NO_2 + H_2O = 2H_2SO_4 + N_2O_3$$

in which the sulphurous oxide from the burning pyrites or sulphur is oxidized to sulphuric oxide by the nitrogen trioxide, passing through the intermediate stage of the formation of nitrosyl sulphuric acid which upon contact with water vapor produces sulphuric acid and regenerates the nitrogen trioxide. If the supply of steam be insufficient, white crystals of the nitrosyl sulphuric acid (*lead chamber crystals*) will also form; when steam enters in larger amount they disappear, with formation of sulphuric acid, while red fumes are given off, thus:

$$2HSO_3(NO_2) + H_2O = 2H_2SO_4 + N_2O_3$$

Preparation on the Large Scale.—Large quantities are manufactured in the United States, England, France, and Germany. Smaller amounts are prepared in Austria, Italy, Belgium, Russia and Japan, and additional amounts in Spain and in Scandinavian countries.

As made from pyrites, the process is as follows: Beginning with the pyrites-kilns, or burners, the broken mineral is placed in moderate-sized lumps on the bars of the burners, which have previously been heated to redness, and when the burning is once started, the fire is kept up by placing a new charge on the top of that nearly burned out. The ordinary charge for each burner of pyrites, containing about 48 per cent. of sulphur, is from 5 to 6 cwt., which is burnt out in twenty-four hours. The hot sulphur dioxide and air are drawn from the pyrites-burners through the whole system of tubes, towers, and chambers by help of the powerful draught from a large chimney which is placed in connection with the apparatus. These gases then pass either into a tall tower (called the Glover or denitrating tower), where they meet a descending stream of strong sulphuric acid charged with nitrous fumes, which at this moment of descent is mixed with a weaker sulphuric acid, thereby liberating the nitrous fumes which then mix with the sulphur dioxide and air, or they are charged with nitrous fumes direct from the nitre-pots, where a mixture of Chili saltpetre and sulphuric acid liberates them. The mixed gases are then delivered at a temperature of about 75° C. into the first of the leaden chambers. These chambers, of which there are three, are now made of much larger size than was formerly the case, having often a capacity of 38,000 cubic feet. Here the gases meet jets of steam and deposit liquid sulphuric acid, as also in the second chamber. In the third or exhaust chamber all the sulphur dioxide should have been converted into sulphuric acid, and red nitrous fumes must always be visible. These must not be lost, but are drawn into a so-called Gay-Lussac tower filled with coke, over which a finely divided shower of strong acid is allowed to fall. The nitrous fumes are absorbed by this, and give the so-called nitrated acid used as before mentioned in the Glover tower. The acid obtained in the leaden chambers has a sp. gr. of 1.55, or contains 64 per cent. of H_2SO_4. The acid which comes from the Glover tower (or, in case this is not used, is obtained by further concentration of chamber acid in leaden pans) has a sp. gr. of 1.71, and contains 78 per cent. H_2SO_4. The strongest acid must be procured by still further concentration in glass or platinum vessels, and will contain 98 per cent. H_2SO_4. (Roscoe and Schorlemmer, *Chem.*, vol. i, pp. 321–338.) Within recent years it has been found that to continue the concentration to the limit of 98 per cent. acid in platinum vessels is very destructive to these. Therefore it has been proposed, after a strength of 65° B. or about 90 per cent. acid has been reached, to finish in vessels of cast iron. It is found that the concentrated acid does not attack this, and therefore it can be substituted for platinum to advantage. Another method of concentrating is that of Gaillard in which the weak acid is made to fall in the form of a fine spray from the top of a tall tower, being met by a current of hot gases from a coke generator which cause the vaporization of the water, and the acid is thus concentrated to a strength ranging from 92 to 97 per cent. Hundreds of plants are now using this method of concentration. The Schwarzenberg tower is an apparatus used to aid in the removal of arsenic for specially pure acid. In it the sulphuric acid meets a current of H_2S which converts the arsenic into sulphide.

According to theory, 100 parts of sulphur burnt should yield 305.9 parts of pure sulphuric acid. In practice the yield is 290 to 294. The amount of sodium nitrate used varies very much. Manufacturers who employ Glover and Gay-Lussac towers require from 3.5 to 6.5 parts of nitrate for every 100 of sulphur burnt, while works unprovided with these appliances may take from 12 to 13 parts. (Roscoe and Schorlemmer, *Chem.*, vol. i, p. 337.)

In 1901, the "Badische Anilin and Sodafabrik" began on a large scale the manufacture of sulphuric acid by what is known as the "contact process," and since then this process has developed very successfully, and is now in use in this country in a number of the newer chemical works. It is rather a process for the manufacture, on a commercial scale, of sulphur trioxide, which then can be allowed to take up the necessary amount of water to form acid of any strength. A mixture of sulphur dioxide and purified air is passed over heated platinized asbestos, which is the so-called "contact material." To make the process successful, the sulphur dioxide gas must be washed to free it from dust, and all traces of volatile arsenic compounds (arising from arsenical pyrites) must be absent; in addition, the temperature must be regulated with great care to avoid the dissociation of the sulphur trioxide formed. The sulphur trioxide can be marketed as anhydride or as concentrated sulphuric acid of any desired strength.

What is said above relates to the mode of preparing common sulphuric acid; but there is another kind, known on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen,* so-called from its properties, and a place in Saxony where it was first manufactured. This product is known in commerce, in the industries where it is used, simply as *oleum.* It is also called *pyro sulphuric acid* or *di-sulphuric acid.* This acid is obtained by distilling dried ferrous sulphate in large stoneware retorts, heated to redness, and connected with receivers of glass or stoneware. The fuming acid distils over, and ferric oxide is left in the form of *colcothar* or *polishing rouge,* a material used for polishing metals, particularly gold and silver. The formula usually given for fuming sulphuric acid is $H_2S_2O_7$ or $H_2SO_4 + SO_3$. This would demand about 45 per cent. of sulphuric oxide or SO_3. In fact, the so-called Nordhausen acid seldom contains more than 10 per cent. of SO_3, and to obtain that demanded by the formula a re-distillation is necessary. This product is semi-solid and is now obtainable in commerce; put up in sealed glass flasks. Its sale has been largely curtailed lately, owing to the introduction into commerce of the *anhydride* under the name of *solid sulphuric acid. Sulphuric oxide* (*solid sulphuric acid*) under 18° C. is in small, colorless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapor of an acid odor. Above 18° C. it is a liquid, very nearly of the density 2.

When moisture is rigidly excluded, the acid has little action on metals, and it is put up in soldered boxes of tinned sheet-iron; it is used largely in the arts in the manufacture of artificial alizarin and indigo. *Persulphuric acid* and the *persulphates* are among recent products of electrolysis. The ammonium persulphate, $(NH_4)_2S_2O_8$, and potassium persulphate, $K_2S_2O_8$, both form white crystalline salts. The former has already found a considerable technical application as an energetic oxidizing agent in the manufacture of organic dye-stuffs and the cyanide extraction of gold.

The fuming sulphuric acid is also prepared by passing the SO_3 of the contact method through strong sulphuric acid. In this way *oleum* containing as high as 80 per cent. of free SO_3 may be obtained.

Kohlrausch (*Pogg. Ann. Erganzungs,* Bd. viii, p. 675, Lunge) found the specific gravity of pure sulphuric acid, to be 1.8342, and believes that a higher sp. gr. than this is due to impurities (probably lead sulphate). The commercial acid is seldom of this strength. According to Phillips, it has generally the sp. gr. 1.8433, and this is about the strength of the Br. acid, of which the sp. gr. is stated to be 1.841 at 15.6° C. The specific gravity of the U. S. P. acid is about 1.83 at 25° C.; the British acid contains about 95 per cent. of absolute sulphuric acid and the U. S. P. X acid not less than 93 per cent. nor more than 95 per cent. of H_2SO_4. Mendelejeff, after a careful determination, found that pure monohydrated sulphuric acid had the specific gravity 1.8371 at 15° C. compared with water at its maximum density, 4° C. (*Am. Drug.,* 1885, p. 16.) The strong acid boils at 338° C., and freezes at $-26°$ C. When diluted, its boiling point is lowered. When of the sp. gr. 1.78 it deposits crystals of the formula $H_2SO_4 + H_2O$ at about 0° C., and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases it forms a numerous class of salts, called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, liberating carbon, and turning them black. A small piece of cork or wood dropped into the acid will for this reason render it of a dark color. It absorbs water with avidity, and is used as a desiccating agent. It has been ascertained by W. B. and R. E. Rogers to be capable of absorbing 94 per cent. of carbon dioxide, a fact having an important bearing on analytical operations.

Description and Physical Properties.—" A colorless, odorless liquid of oily consistence, very caustic and corrosive. Sulphuric Acid is miscible with water and with alcohol with the evolution of much heat. The Acid must be added with great caution to the diluent. When strongly heated, the Acid is vaporized with the evolution of dense, white fumes. Specific gravity: about 1.83 at 25° C.

" It is strongly acid to litmus paper even when highly diluted. Sulphuric Acid responds to the reactions for sulphates. Sulphuric Acid with or without the aid of heat chars cane sugar, wood, and many other organic substances.

" No precipitate is formed within an hour on mixing 1 volume of Sulphuric Acid with 5 volumes of alcohol (*lead*). Sulphuric Acid diluted with 15 volumes of distilled water conforms to the following tests: Evaporate 25 cc. of the dilution from a platinum or porcelain dish, and ignite: not more than 0.0015 Gm. of residue remains after ignition (*non-volatile substances*). A 10 cc. portion of the dilution does not at once discharge the color of 0.1 cc. of tenth-normal potassium permanganate (*sulphurous or nitrous acid*). Mix 5 cc. of the dilution with an equal volume of ferrous sulphate T.S., and superimpose it upon reagent sulphuric acid: the zone of contact does not assume a brown or brownish-red color (*nitrate*). The dilution is not immediately affected by silver nitrate T.S. (*chloride*). A 10 cc. portion of the dilution meets the requirements of the test for *heavy metals.* A 2 cc. portion of the dilution meets the requirements of the test for *arsenic.*

" **Assay.**—Proceed as directed under the assay for acids, using about 1 cc. of the Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.04904 Gm. of H_2SO_4.

"Preserve in glass-stoppered bottles." *U. S.*

"A colorless, corrosive, intensely acid liquid of oily consistence, evolving much heat on the addition of *water.* Yields, when neutralised, the *reactions* characteristic of sulphates. Specific gravity about 1.841. 1 gramme diluted with 20 or 30 millilitres of *water* requires for neutralisation not less than 19.3 millilitres of *N/1 solution of sodium hydroxide.* Yields no characteristic *reactions* for copper, iron ammonium, chlorides, nitrates, nitrites, or sulphites. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. *Hydrochloric acid* to which *sodium sulphite* has been added, when poured carefully upon an equal volume of Sulphuric Acid contained in a test-tube, does not cause a red coloration at the junction of the two liquids, and no red precipitate forms on warming the tube (absence of selenium). Leaves not more than 0.05 per cent. by weight of solid residue on evaporation." *Br.*

For official tables showing specific gravity of various strengths of sulphuric acid, see Part III.

Occasionally potassium nitrate is added to render dark samples of acid colorless. This addition gives rise to the impurity of potassium sulphate. These impurities often amount to 3 or 4 per cent. The commercial acid cannot be expected to be absolutely pure; but when properly manufactured it should not contain more than one-fourth of 1 per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the acid, when they will remain. If lead sulphate be present, the acid will become turbid on dilution with an equal bulk of water. This impurity is not detected by hydrogen sulphide unless the sulphuric acid be saturated with an alkali. If only a scanty white turbidity arise, the acid is of good commercial quality.

Arsenic is sometimes present in sulphuric acid. In consequence of the high price of Sicilian sulphur, most English manufacturers have employed iron pyrites for the purpose of furnishing the necessary sulphurous acid in the manufacture of oil of vitriol. As the pyrites usually contains arsenic, it happens that the sulphurous acid fumes are accompanied by arsenous oxide, and thus the sulphuric acid becomes contaminated. From 22 to 35 grains of arsenic trioxide have been found in 20 fluidounces of oil of vitriol, of English manufacture, by G. O. Rees and Watson, and a still larger proportion by J. Cameron of South Wales. It may readily be discovered by the official tests for arsenic.

Until within recent years all the sulphuric acid produced in the United Sates was made from sulphur. At the present time many of the sulphuric acid works are using pyrites. Most of the American pyrites ore is entirely free from arsenic. Another impurity occasionally existing in French sulphuric acid is selenium, supposed to be derived from copper pyrites sometimes substituted for sulphur in the manufacture of the acid.

Apart from the destructive effect which strong sulphuric acid has upon almost all forms of organic matter, its incompatibilities in general are those of the diluted acids, which see.

Uses.—For the therapeutic powers and uses of sulphuric acid when administered internally, see *Acidum Sulphuricum Dilutum.* Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for that purpose, and should be applied with caution. A plan, however, has been proposed by Simpson by which it becomes very manageable. This consists in mixing it with dried and powdered zinc sulphate sufficient to give it a pasty consistence. *Michel's Paste* consists of strong sulphuric acid three parts, and finely powdered asbestos one part, thoroughly rubbed together. Mixed with saffron to the consistence of a ductile paste, Velpeau found it a convenient caustic not liable to spread or be absorbed, and producing an eschar which is promptly detached.

Toxicological Properties.—The symptoms of poisoning by this acid are the following: Burning heat in the throat and stomach, extreme fetidness of the breath, nausea and excessive vomitings of black or reddish matter, excruciating pains in the bowels, difficulty of breathing, extreme anguish, a feeling of cold on the skin, great prostration, constant tossing, convulsions, and death. Sometimes there is no pain whatever in the stomach, sensibility being apparently destroyed by the violence of the caustic action. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or, if this be not at hand, of solution of soap or other alkali. The safety of the patient depends upon the greatest promptitude in the application of the antidotes. After the poison has been neutralized, mucilaginous and other bland drinks must be taken freely.

Upon the skin sulphuric acid acts as a very rapid and powerful corrosive. When it has been spilled or thrown upon the person the part should be immediately washed with a weak solution of sodium carbonate or bicarbonate, or soap may be well rubbed into the surface. After the removal and neutralization of the acid, Carron oil or similar protective may be applied. Further treatment is that of a burn.

The holes burnt in linen by sulphuric acid, so long as the texture is undisturbed, are distinguished from those produced by red-hot coals, by the paste-like characters of their edges.

Uses in the Arts.—Sulphuric acid is more used in the arts than any other acid. It is employed to obtain many of the other acids; to make alum and ferric sulphate; to refine petroleum and paraffin; to decompose the neutral fats; to dissolve indigo; to prepare phosphorus, chlorinated lime, magnesium sulphate, etc. Petroleum refining, manufacture of smokeless powder and other nitrated explosives, and manufacture of fertilizers from phosphatic materials consume the largest amounts of sulphuric acid in the United States.

Off. Prep.—Acidum Sulphuricum Aromaticum, *U. S., Br.;* Acidum Sulphuricum Dilutum, *U. S., Br.;* Acidum Sulphurosum, *Br.*

ACIDUM SULPHURICUM AROMATICUM. U. S., Br.

AROMATIC SULPHURIC ACID Acid. Sulph. Arom.

"Aromatic Sulphuric Acid contains free sulphuric acid and ethyl-sulphuric acid together equivalent to not less than 19 per cent. nor more than 21 per cent. of H_2SO_4." *U. S.*

Tinctura Aromatica Acida; Elixir of Vitriol; Elixir vitriolique, Teinture (alcoolé) aromatique sulphurique, *Fr.;* Saure Aromatische Tinktur, Elixir Vitrioli Mynsichti, Mynsicht's Elixir, G.

"Aromatic Sulphuric Acid contains free sulphuric acid and ethylsulphuric acid together equivalent to not less than 19 per cent. and not more than 21 per cent. of H_2SO_4. Sulphuric Acid, 109 cc.; Tincture of Ginger, 50 cc.; Oil of Cinnamon, 1 cc.; Alcohol, a sufficient quantity to make 1000 cc. Add the sulphuric acid gradually and with great caution to 700 cc. of alcohol, and allow the mixture to cool. Then add to it the tincture of ginger and the oil of cinnamon, and afterwards enough alcohol to make the product measure 1000 cc." *U. S.*

"Tincture of Ginger, 250 millilitres; Spirit of Cinnamon, 15 millilitres; Sulphuric Acid. 70 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Mix the Sulphuric Acid gradually with six hundred millilitres of the Alcohol; cool to 15.5° C.; add the Spirit of Cinnamon and Tincture of Ginger and sufficient of the Alcohol to produce the required volume." *Br.*

The British formula is similar in flavor but weaker in acid containing only about 12.5 per cent.

Description and Physical Properties.—"A clear, reddish-brown liquid having a pleasant aromatic odor. Specific gravity: about 0.94 at 25° C. Aromatic Sulphuric Acid is strongly acid to litmus paper. Aromatic Sulphuric Acid responds to the reactions for sulphates.

"Preserve in glass-stoppered bottles." *U. S.*

Aromatic sulphuric acid of the older Pharmacopœias was of a deep reddish-brown, but it is a straw-colored liquid when freshly prepared according to the directions of the U. S. Pharmacopœia IX, of a peculiar aromatic odor, and, when sufficiently diluted, of a grateful acid taste. It cannot, however, be viewed merely as a sulphuric acid diluted with alcohol and containing essential oils, for the difference between fresh and old preparations is quite marked, and a peculiar and agreeable ethereal odor is developed by age. The U. S. official definition recognizes the presence of ethyl sulphuric acid.

"**Assay.**—Transfer about 5 cc. of Aromatic Sulphuric Acid, accurately weighed, to a tall beaker. Add exactly 30 cc. of normal sodium hydroxide, and evaporate the mixture to complete dryness on a sand bath. Dissolve the residue in 30 cc. of distilled water, and titrate the excess of alkali with normal sulphuric acid, using methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.04904 Gm. of H_2SO_4." *U. S.*

"Specific gravity 0.917 to 0.923. 10 millilitres require for neutralisation not less than 24.9 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

Uses.—This valuable preparation is tonic and astringent. It acts precisely as does the *Acidum Sulphuricum Dilutum.* Water produces a turbidity in this preparation owing to the precipitation of the oil and resin of the aromatics, otherwise the incompatibilities are the same as those of diluted sulphuric acid, which see.

Dose, from five to fifteen minims (0.32–1.0 cc.), in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured.

ACIDUM SULPHURICUM DILUTUM. U. S., Br.

DILUTED SULPHURIC ACID Acid. Sulph. Dil.

"Diluted Sulphuric Acid is an aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent of H_2SO_4." *U. S.* "Diluted Sulphuric Acid contains 10 per cent. by weight of hydrogen sulphate, H_2SO_4." *Br.*

Acide sulphurique dilué *Fr.;* Acidum sulphuricum dilutum, *P. G.;* Verdünnte Schwefelsäure, *G.*

"Sulphuric Acid, 107 Gm.; Distilled Water, 893 Gm.; to make 1000 Gm. Pour the Acid gradually, with constant stirring, into the distilled water, and allow the solution to cool." *U. S.*

"Sulphuric Acid, 112.5 grammes; Distilled Water, 940.0 millilitres, or a sufficient quantity. Add the Sulphuric Acid very gradually to one-half of the Distilled Water contained in a glass flask; cool to 15.5° C. and add sufficient Distilled Water to make the resulting liquid respond to the following tests." *Br.*

Description and Physical Properties.—"A colorles, odorless liquid having a strongly acid taste. Specific gravity: about 1.067 at 25° C.

"Diluted Sulphuric Acid is strongly acid to litmus paper. Diluted Sulphuric Acid conforms to the tests for identity and purity under *Acidum Sulphuricum.*

"**Assay.**—Proceed as directed under the assay for acids, using 20 cc. of the Acid, accurately weighed, and methyl orange T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.04904 Gm. of H_2SO_4.

"Preserve in glass-stoppered bottles." *U. S.*

"Specific gravity 1.069. 10 millilitres require for neutralisation 21.7 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

This preparation is sulphuric acid diluted to such an extent as to make it convenient for prescription. The British Pharmacopœia, 1914, lowered slightly the specific gravity of this acid and now corresponds with that of the U. S. The difference is not so great as to be of practical importance. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel.

Uses.—Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in *typhoid fever,* and often with advantage. In the convalescence from protracted fevers it acts beneficially as a tonic, exciting the appetite and promoting digestion. It is a valuable astringent in *serous diarrheas* and is also frequently used, but with less reason, in *colliquative sweats.* Buxton, of London, called attention to its great value in *choleraic diarrheas;* his assertions have received abundant confirmation both in this country and in England. It has even been recommended in *asiatic cholera.* It is added with advantage to infusions of cinchona, the alkaloids of which it tends to hold in solution. As it is injurious to the teeth, it is best taken through a glass tube. It is much less used in the United States than is the aromatic sulphuric acid.

All forms of sulphuric acid show incompatibility with salts of lead, barium, strontium, and calcium, forming insoluble precipitates of the corresponding sulphates. With hypophosphorous acid or hypophosphites, it is reduced to sulphurous acid and finally to sulphur.

Dose, ten to thirty minims (0.6–1.8 cc.).

ACIDUM SULPHUROSUM. Br.

SULPHUROUS ACID

" Sulphurous Acid is an aqueous solution containing 6.4 per cent. by weight of hydrogen sulphite, H_2SO_3, corresponding to 5 per cent. by weight of sulphur dioxide, SO_2. The sulphur dioxide may be obtained by heating sulphuric acid with charcoal or sulphur." *Br.*

Acide sulfureux, *Fr.;* Schwefligsäure, Schwefligsäurewasser, *G.*

Sulphurous acid was not admitted to Part I of the U. S., but was placed among the reagents (see Part III). There is no process for making it at present official. The U. S. VIII method of preparation is:

"Sulphuric Acid, *sixty cc.;* Charcoal, in coarse powder, *twenty grammes;* Distilled Water, *five hundred cc.* Introduce the Charcoal into a glass flask having a capacity of about *five hundred cc.,* add the Acid, and mix them well. Connect the flask by means of bent glass tubing, about fifty centimeters in length, with a wash bottle having a capacity of about two hundred cc. containing about *fifty cc.* of water, so that the end of the inlet tube shall be below the surface of the water. Through the triply perforated rubber stopper of the wash-bottle pass a safety tube, which should reach nearly to the bottom of the bottle, and connect the latter, by means of a glass tubing, with a bottle provided with a doubly perforated rubber stopper, having a capacity of about one thousand cc., and containing *five hundred cc.* of well-cooled Distilled Water. The inlet tube should dip about twenty-five millimeters below the surface of the Distilled Water. By means of a second tube connect this bottle with another containing water, the end of the tube extending five centimeters below the surface. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the Sulphuric Acid and Charcoal, until the evolution of gas has nearly ceased, and, during the passage of the gas, keep the bottle containing the Distilled Water at or below 10° C., by surrounding it with cold water or ice. Assay a small portion of the Sulphurous Acid by the method given below. Then add to the remainder sufficient Distilled Water to bring the product to the strength of 6.4 per cent., by weight, of sulphur dioxide. Finally pour the Sulphurous Acid into dark, amber-colored, glass-stoppered bottles, which should be completely filled, and kept in a cool place, protected from light. Owing to its rapid deterioration, Sulphurous Acid should be frequently assayed, and none should be dispensed, if it fails to conform to the assay given below." *U. S. VIII.*

This process is essentially that of Wittstein.

For further details concerning this process and its modifications see *U. S. D.,* 20th ed., p. 73.

F. L. Cheney devised a method of making sulphurous acid extemporaneously as follows: Dry acid sodium sulphite, 5.7 Gm.; dilute hydrochloric acid, 18.5 cc.; water, 25 cc. Add the acid to the salt, placed in a half pint glass-stoppered bottle, stopper immediately and set aside in a cool place. Agitate slowly to aid in the solution of the salt, and when bubbles cease to arise, add the water and shake the bottle for a few minutes. The product should measure 40 cc. and assay from 6 per cent. to 6.5 per cent. SO_2. When it is necessary to have a fresh solution of sulphurous acid and the presence of a small amount of sodium chloride is admissible, this process will be found convenient. (*A. J. P.,* 1906, 333.) This process was modified by Otto Raubenheimer (*J. A. Ph. A.,* 1917, vi, 352. R. W. Terry proposes a still different method in which SO_2 is generated from anhydrous Na_2SO_3 with H_2SO_4 and the gas collected in a Woulffe bottle. (*J. A. Ph. A.,* 1917, vi, 484.)

Sulphur dioxide in liquefied form in cylinders is now commercially available even in small amounts, so it is rarely necessary at present to make the sulphurous acid by any of the older processes as all that is necessary is to pass the SO_2 into water with suitable precautions.

Properties.—Sulphurous acid is a solution of sulphurous oxide gas. The oxide is an irrespirable gas, of a suffocating odor familiar to every one as that of burning sulphur, which is converted into it by combustion. If inhaled in the concentrated state, it proves fatal. Cold reduces it to a colorless liquid, which boils at –10.5° C. It has the sp. gr. 2.21, liquefies at –10° C., has a strong acid reaction, extinguishes burning bodies, has the power of bleaching many colored substances, and has a strong affinity for oxygen, with which it gradually combines in the presence of water, forming sulphuric acid. Water at 18° C takes up about 50 volumes of gas, and the solution has the sp. gr. 1.04. (Brande and Taylor.)

Sulphurous acid sometimes exists as an impurity in hydrochloric, acetic, and other acids; according to P. Schweitzer, the minutest quantity may be detected by dissolving zinc in the suspected acid, when, if sulphurous acid be present, hydrogen sulphide will be evolved, recognizable by its odor. (*Chem. News,* xxviii, 293.)

When sulphurous acid is exposed to the air it slowly absorbs oxygen, with the formation of sulphuric acid, and acquires a sour taste, and the property of changing vegetable blues to red differing in this respect from the original sulphurous acid which bleaches vegetable colors. When kept in closed vessels exposed to the sunlight, a portion of it is decomposed, sulphur being deposited and sulphuric acid formed by the union of the liberated oxygen with other portions of the acid. (*A. J. P.,* xlii, 352.) It should be entirely volatilized by heat. It decolorizes iodine by producing hydriodic acid, and on this fact is based the Br. test given below. It decomposes calcium phosphate.

"A colorless liquid with a pungent, sulphurous odor. Yields, when neutralised, the *reactions* characteristic of sulphites. Yields not more than a slight precipitate with *solution of barium chloride* (limit of sulphates), but a copious precipitate if *solution of chlorine* is also added. Leaves no appreciable residue on evaporation. Specific gravity 1.025. 1 gramme, diluted with 100 millilitres of recently boiled and cooled *water,* requires 15.5 millilitres of *N/10 solution of iodine* for complete oxidation, *mucilage of starch* being used as indicator. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Assay.—A process for its assay will be found in Part III, where this acid appears as a reagent.

Uses.—Sulphurous acid in concentrated solutions is a powerful germicide, but probably no more so than are the other mineral acids. The disinfectant value of burning sulphur is due to the formation of this acid; during the process of combustion sulphur dioxide is formed and if there be present in the air an abundance of aqueous vapors this will unite with the water to form sulphurous acid which has a destructive action on many forms of life including the less resistant bacteria. It is, however, difficult to generate sufficient sulphurous acid by this method to have any real bactericidal effect, and the method of disinfecting sick rooms has been almost completely abandoned in favor of the more efficient and less destructive formaldehyde. It is, however, often useful for the destruction of vermin. It is quite impossible to hope for any true disinfectant action by burning sulphur candles in the manner which is so popularly resorted to; the most that can be hoped for is a deodorizing effect. By virtue of its reducing properties sulphurous acid decomposes hydrogen sulphide, and like other acids will unite with ammonia to form relatively inodorous compounds. It must also be remembered that sulphurous acid has a bleaching effect due to its reducing power and is therefore likely to be injurious to various kinds of clothing and furniture which are exposed to its fumes. Sulphurous acid and sulphites have been widely used for preserving food, but are now prohibited by the laws of many states. They are still permitted for the preservation of dried fruits where the function is to prevent darkening during drying and from which they are largely removed by the preliminary washing and subsequent cooking to which these foods are subjected before being eaten. So-called "sulphite powders" containing either sodium sulphite or calcium or magnesium bi-sulphites have figured largely as food preservatives. Sulphurous acid is also used for its bleaching properties to decolorize various products and make them look pure and colorless, and as a preliminary step to their subsequent dyeing, as in so-called "maraschino" or cocktail cherries. For a method of determining sulphurous acid in foodstuffs and allied products, see *Circular of the U. S. Dept. of Agriculture,* 1906, No. 28, pp. 11–12.

Its use in food products, however, should not be encouraged as it is well demonstrated that the contined ingestion of sulphites is injurious to the kidneys.

Externally sulphurous acid is used in various *skin diseases,* such as *scabies, ringworm* and *impetigo contagiosa* for its parasiticide effect. For local application it should be diluted with two or three parts of water or glycerin and applied as a lotion or by cloths wet with this solution. Intenally it has been used as a gastric antiseptic in *pyrosis* and in cases of *sarcinæ ventriculi,* but has been almost entirely replaced by the acid sulphite of sodium.

The incompatibilities of sulphurous acid are those of any powerful reducing agent. It will decompose many metallic salts, as of mercury, with the liberation of metallic mercury. Oxidizing compounds readily change it to sulphuric acid.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

ACIDUM TANNICUM. U. S., Br.

TANNIC ACID Acid. Tann. [Gallotannic Acid, Tannin]

"A tannin usually obtained from nutgall." *U. S.* "Tannic Acid, $C_{14}H_{10}O_9$, may be extracted by water-saturated ether from galls which have been subjected to a special fermentation." *Br.*

Digallic Acid; Acidum Gallo-tannicum Tanninum; Acide tannique, *Fr.;* Acidum tannicum, *P. G.;* Gerbsäure, Gallusgerbsäure, *G.*; Acido tannico, *It.;* Acido tanico, *Sp.*

The U. S. and the Br. do not give a detailed process for preparing tannic acid; the former British Pharmacopœia adopted a process which was almost identical with that of the U. S. P., 1870, both being essentially the process of Leconnet, modified by Dominé, which had been substituted for that of Pelouze previously employed in both Pharmacopœias. The process of the British Pharmacopœia (1855) was as follows: "Galls in powder, Ether, of each a sufficient quantity. Expose the powdered galls to a damp atmosphere for two or three days, and afterwards add sufficient ether to form a soft paste. Let this stand in a well-closed vessel for twenty-four hours, then, having quickly enveloped it in a linen cloth, submit it to strong pressure in a suitable press, so as to separate the liquid portion. Reduce the pressed cake to powder, mix it with sufficient ether, to which one-sixteenth of its bulk of water has been added, to form again a soft paste, and press this as before. Mix the expressed liquids, and expose the mixture to spontaneous evaporation until, by the aid subsequently of a little heat, it has acquired the consistence of a soft extract; then place it on earthen plates or dishes, and dry it in a hot-air chamber at a temperature not exceeding 212° F." *Br.* (1885).

While the Pelouze process yields the tannic acid probably in a somewhat purer state than Leconnet's, it is less easy of performance, and much less productive, and the product of the above formula is sufficiently pure for all practical purposes. The addition of a little alcohol —8 per cent., for example—to the ethereal menstruum still further increases the product. The exposure of the powdered galls to a damp atmosphere for two or three days is for the purpose of inducing a special fermentation, whereby the yield of tannin is materially increased. There appear to be two coloring principles in galls, one soluble in ether and not in alcohol, the other in alcohol and not in ether. Hence, while the tannic acid, in whichever way procured, is yellowish, that obtained by ether has a greenish tint, while that obtained by the addition of alcohol is slightly brownish. In consequence of the mode in which the acid is dried, in thin layers, on tinned or glass plates, and equally exposed to the heat above and below, it froths up on the escape of the ether, and concretes in a soft, cellular, friable form, which is strikingly characteristic of the preparation made in strict accordance with the formula. Further discussion of these methods will be found in the *U. S. D.*, 20th ed., p. 75.

From 30 to 35 per cent. of tannic acid is obtained from galls by Pelouze's method; 60 per cent. by that of Leconnet. Alcohol tannin and water tannin are terms used to indicate the method of extraction; in the former the powdered nutgall is percolated with alcohol (50 per cent.) and the solution of tannin evaporated in a vacuum apparatus; in the water tannin, water is used as in the ether process as above described and the aqueous solution evaporated *in vacuo*. Gartenmeister used acetic ether for a solvent and a patent was secured for this process in Germany.

"Crystallized" tannic acid is said to be made by forcing a thick syrupy tannin solution through finely perforated sieves and dropping the threads from a height upon rapidly revolving wooden cylinders and scraping off the product. The term crystallized is, of course, a misnomer, as tannin is amorphous.

Henry Trimble and J. C. Peacock recommend acetone as a valuable solvent for extracting tannin from oak bark (*Proc. A. Ph. A.*, 1893, p. 110), and acetone is now largely used by manufacturers as a solvent in extracting tannin from galls. B. L. DeGraffe (*A. J. P.*, 1896, 313) recorded investigation upon the plants of the Ericaceæ to determine the character of their tannins; acetone and acetic ether were used as solvents. For Sisley's method of preparing *pure* tannin, see *Proc. A. Ph. A.*, 1894, 1087.

Composition.—The term "tannin" is applied to a group of vegetable principles which have the following chemical properties: (1) They are mostly uncrystallizable colloidal substances with astringent properties; (2) They precipitate gelatin-yielding tissues, a property which enables them to convert hide into leather; (3) They all give blackish-blue or blackish-green colors with ferric salts, a fact which is made use of in the manufacture of ink; (4) They are precipitated from solution by many metallic salts such as copper or lead acetates or stannous chloride, etc.; (5) They are precipitated from solution by a strong aqueous solution of potassium bichromate or by a 1 per cent. solution of chromic acid; (6) They precipitate from aqueous solution both alkaloids and other organic substances of a basic nature, such as basic organic coloring matters; (7) In alkaline solution, the tannins, and many of their derivatives, readily absorb oxygen, becoming dark in color; (8) With a solution of potassium ferricyanide and ammonia they give a deep red color. It must be borne in mind, however, that none of these reactions, taken separately, are specific for tannins; they may be given by other substances as well, but all true tannins answer them as a whole.

Some authors include also among the tannins vegetable principles which have all of these properties except that of precipitating gelatin; on the other hand Dekker prefers to regard those substances which do not give this reaction as *pseudo-tannins* and includes under this heading caffetannic acid and the tannins of *Portlandia grandiflora, Asperula odorata, Rubia tinctorum, Scrophularia nodosa, Humulus Lupulus, etc.* Similarly, Procter points out that such substances as moringatannic acid, or maclurin, and caffetannic and lupulotannic acids, are more closely related to the coloring matters than to the tannins; maclurin which is a pentahydroxybenzophenone is the yellow coloring matter occurring in the substance known as fustic, obtained from the wood of *Chlorophora tinctoria* (see *Fustic,* Part II). The tannin used in pharmacy and medicine is called, for the sake of distinction, *gallotannic acid.* According to Pettenkofer, it is found only in perennial plants, indicating some relation to the production of woody fiber. (*Buchner's Neues Repert.,* iii, 74–76.) Henry Trimble (*The Tannins,* vol. ii, p. 132, Phila., 1894) classifies the tannins into two main groups: Group *a.* Gallotannic acid, chestnut wood tannin, chestnut bark tannin, pomegranate bark tannin and sumac tannin. Group *b.* Oak bark tannin, mangrove tannin, canaigre tannin, rhatany tannin, kino tannin, catechu tannin, and tormentil tannin. Group *a.* Give blue-black precipitates with iron salts, group *b.* greenish or brownish.

For another scheme of classification of the tannins, based on the products they yield when heated alone, when heated with diluted acid, and when fused with caustic alkali, see Allen, *Com. Org. Anal.,* 2d ed., vol. iii, part i, p. 77.

We have as yet comparatively little certain knowledge concerning the chemical constitution of even the simplest tannins. Gallo-tannic acid is generally regarded as an anhydride formed by the removal of one molecule of water between two molecules of gallic acid according to the equation:

$$2C_7H_6O_5 - H_2O = C_{14}H_{10}O_9$$

These are differences, however, of opinion with regard to the exact position from which the H and O have been removed. (See also *Acidum Gallicum.*)

Description and Physical Properties.—"An amorphous powder, glistening scales, or spongy masses, varying in color from yellowish-white to light brown. It is odorless, or has a faint, characteristic odor, and a strongly astringent taste. Tannic Acid is very soluble in water, acetone, and alcohol. It is freely soluble in diluted alcohol and slightly soluble in dehydrated alcohol. It is almost insoluble in benzene, chloroform, ether, and in petroleum benzin. One Gm. of Tannic Acid dissolves in about 1 cc. of warm glycerin.

"The addition of a small quantity of ferric chloride T.S. to an aqueous solution of the Acid produces a bluish-black color or precipitate. An aqueous solution of Tannic Acid produces precipitates in solutions of most of the alkaloids and glucosides, and also in solutions of gelatin, albumin, and starch.

"Tannic Acid loses not more than 12 per cent. of its weight when dried to constant weight at 100° C. Ash: not more than 0.5 per cent. Dissolve 2 Gm. of Tannic Acid in 10 cc. of hot distilled water: the solution is not more than slightly turbid, and no turbidity is produced upon diluting separate 5 cc. portions of the cooled and filtered solution with 10 cc. of alcohol (*gum or dextrin*), or with 10 cc. of distilled water (*resinous substances*).

"Preserve in well-closed containers, in a cool place, protected from light." *U. S.*

"A light brownish powder consisting of thin glistening scales. Characteristic odor; taste strongly astringent. Reaction acid. Soluble in 1 part of *water* or of *alcohol* (90 per cent.), and, slowly, in 1 part of *glycerin.* It is precipitated from an aqueous solution by many mineral salts and acids. The aqueous solution precipitates *solutions of isinglass, albumen,* alkaloids, and *tartarated antimony,* and gives with *T. Sol. of ferric chloride* a bluish-black color. Ash not more than 0.2 per cent." *Br.*

Commercial tannic acid often has a decided odor, which is probably owing chiefly to the presence of the odorous principle of the galls, though sometimes to matter derived from the ether with which it is prepared. According to Heinz, the odor is due to a greenish resinous principle, which may be separated by dissolving the acid in twice its weight of hot water, adding one-fourth part of ether, agitating slowly, allowing the coagulated coloring matter to precipitate, filtering, and evaporating. (*J. P. C.,* xv, 308.)

When tannic acid, iodine, and water are mixed, a reaction takes place, by which the water is decomposed, its hydrogen forming with the iodine hydriodic acid, which combines with a portion of the tannic acid and remains in solution, while the oxygen of the water combines with another portion of the tannic acid to form a compound, which, being insoluble, is precipitated. The iodized solution thus obtained is capable of dissolving more iodine, and holding it in permanent solution, however, much diluted. This compound is the basis of the preparation known as *syrupus Iodotannicus* of the National Formulary. Iodine in a liquid containing tannic acid cannot be detected by starch, but if the liquid is placed in a watch-glass, ferrous sulphate added, and the glass covered with starch paper, ferric tannate being precipitated, the blue color soon appears.

Griessmayer (*Zeit. An. Chem.,* 1873) proposes a test for tannin and free alkalies. On mixing a drop of a solution of tannin with 1 cc. of 1/100 normal solution of iodine, the reddish color of the iodine solution instantly disappears; if one drop of solution of ammonia be now added (previously diluted with ten times its bulk of water), a brilliant red color is produced which is quite permanent. Tannic acid precipitates solutions of starch, albumin, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather. J. Napier Spence (*J. Soc. Chem. Ind.,* 1891, p. 1114) has reviewed all the current tests for distinguishing between tannic acid and gallic acid. (See *Proc. A. Ph. A.,* 1892, p. 1032.)

Various plans have been proposed for estimating the quantity of tannic acid, which is an object of importance to tanners, as enabling them to judge of their tanning materials. John H. Yocum, after reviewing various methods of estimating tannin, believes the "hide-powder" method most practical and useful. (*J. Am. C. S.*, Jan. 9, 1897.) This was the one adopted by the International Congress of Leather Trades Chemists at Turin, Italy, in 1904, and is still used. For other methods, see *P. J.*, 1885, pp. 121, 850; *J. P. C.*, 1874, p. 445; *West. Drug.*, 1891, p. 445; and a monograph on the *"The Tannins,"* by Henry Trimble. (J. B. Lippincott Company, 1894.)

Uses.—Tannic acid is a powerful astringent and but slightly irritant. It is not capable of being absorbed nor, indeed, of circulating in the blood, because of its property of precipitating all albumin. When taken by the mouth, however, a portion of it combines with the alkalies of the intestinal tract and is probably absorbed as sodium tannate—which is not astringent—and a portion of it is hydrolized to gallic acid which may also be absorbed. As an astringent it is employed locally in chronic *congestions of the throat*, in local *relaxations, as of the uvula* or in *hemorrhoids*, to check excessive secretion, as in mercurial *salivation* or weeping *ulcers*, and as a styptic in various local *hemorrhages*. In *diarrheas* it is often of much service but is not so generally employed in the pure form as in one of the galenicals of crude vegetables containing it, or as some synthetic derivative. The preference of these various drugs which contain tannic acid over the pure substance is owing to their being less readily precipitated by the albumins of the prima viae before they reach the diseased point. Tannic acid is also widely recommended as a chemical antidote to various poisons, especially to the alkaloids and heavy metals. The tannates of the alkaloids are, however, soluble in dilute acids and the use of tannic acid in alkaloidal poisoning can at best be only partially antidotal.

Tannic acid produces insoluble compounds with many metallic salts such as copper, lead, tin and especially iron where the compound possesses the well known inky coloration. Tannic acid is also incompatible with solution of alkaloidal salts from which it throws down the insoluble tannates of the alkaloids, which are not physiologically inert but which need to be suspended or incorporated by shaking in order to avoid danger in dispensing.

Gelatin, albumin and other organic compounds form insoluble combinations with tannic acid. Alkaloids and oxidizing agents decompose tannic acid upon standing in contact in aqueous solutions.

Dose, from three to twenty grains (0.20–1.3 Gm.).

ACIDUM TARTARICUM. U. S., Br.

TARTARIC ACID Acid. Tart.

"Tartaric Acid contains not less than 99.5 per cent. of $C_2H_2(OH)_2(COOH)_2$." *U. S.* "Tartaric Acid may be obtained from acid potassium tartrate, and contains not less than 99 per cent. of hydrogen tartrate, $H_2C_4H_4O_6$." *Br.*

Dextrotartario Acid; Sal Essentiale Tartari; Acide Tartrique, *Fr. Cod.*; Acide du Tartre, Acide dextroracémique, *Fr.*; Acidum tartaricum, *P. G.*; Weinsteinsäure, Weinsäure, *G.*; Acido tartarico, *It.*; Acido tartrico, *Sp.*

No formula for the preparation of tartaric acid is given in either Pharmacopœia. It is prepared from *wine lees*, a by-product of the process of making wine, which is obtained in the initial stages of the process. It is also extracted from *tartar*, or *argol*, a peculiar substance which is deposited on the inside of wine casks during the fermentation. Tartar, when purified and reduced to powder, is the cream of tartar of commerce, and consists of acid potassium tartrate. (See *Potassii Bitartras.*) The following is the former British process:

"Take of Acid Tartrate of Potassium *forty-five ounces* [av.]; Distilled water a *sufficiency;* Prepared Chalk *twelve ounces and a half* [av.]; Chloride of Calcium *thirteen ounces and a half* [av.]; Sulphuric Acid *thirteen fluidounces.* Boil the Acid Tartrate of Potassium with two gallons [Imp. measure] of the Water, and add gradually the Chalk, constantly stirring. When the effervescence has ceased, add the Chloride of Calcium dissolved in two pints [Imp. meas.] of the Water. When the tartrate of calcium has subsided, pour off the liquid, and wash the tartrate with Distilled Water until it is rendered tasteless. Pour the Sulphuric Acid, first diluted with three pints [Imp. meas.] of the Water, on the tartrate of calcium, mix thoroughly, boil for half an hour with repeated stirring, and filter through calico. Evaporate the filtrate at a low temperature until it acquires the sp. gr. of 1.21, allow it to cool, and then separate and reject the crystals of sulphate of calcium which have formed. Again evaporate the clear liquid till a film forms on its surface, and allow it to cool and crystallize. Lastly, purify the crystals by solution, filtration (if necessary), and recrystallization." *Br.* (1885).

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in potassium bitartrate or cream of tartar with calcium carbonate, and decomposing the resulting insoluble calcium tartrate by sulphuric acid, which causes the precipitation of calcium sulphate, and liberates the tartaric acid. The equivalent quantities are two molecules of the acid tartrate and one molecule of calcium carbonate. The process, when thus conducted, furnishes one-half of the tartaric acid. The other half may be procured, as in the British process, by decomposing the neutral potassium tartrate remaining in the solution after the precipitation of the calcium tartrate, by calcium chloride in excess. By double decomposition, potassium chloride will be formed in solution, and a second portion of calcium tartrate will precipitate, which may be decomposed by sulphuric acid together with the first portion. The process, when thus conducted, will furnish twice as much tartaric acid as when the acid salt only is decomposed. The reactions are:

$$2KHC_4H_4O_6 + CaCO_3 = K_2C_4H_4O_6 + CaC_4H_4O_6 + H_2O + CO_2$$
$$CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$$
$$K_2C_4H_4O_6 + CaCl_2 = 2KCl + CaC_4H_4O_6$$
$$CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$$

Scarlata (*Chem. News,* 1899, 296) has devised a method of making tartaric acid based on the decomposition of potassium and calcium tartrates by *fluosilicic acid;* tartaric acid is liberated and corresponding fluosilicates are formed; the latter may then be decomposed by sulphuric acid and fluosilicic acid reproduced for use in a subsequent operation. By this method tartaric acid of 99 per cent. purity may be obtained. Zinno has prepared tartaric acid synthetically by passing carbon dioxide under pressure over potassium glycerate. (*Proc. A. Ph. A.,* 1902, 263.)

Preparation on the Large Scale.—To obtain tartaric acid from the crude materials (argol and wine lees), the method still largely used is the precipitation of the acid potassium tartrate as calcium tartrate and subsequent preparation of the tartaric acid from the latter. The methods of obtaining the calcium tartrate vary according to the nature of the crude material. A suitable method of producing it from argol is to mix the argol, preferably in the form of a powder, with water, and boil, after the addition of some hydrochloric acid. Milk of lime is then added to the boiling mass until this is nearly neutral, when calcium tartrate is precipitated and neutral potassium tartrate and calcium chloride left in solution. The neutral potassium tartrate is decomposed either by boiling with a sufficient amount of calcium sulphate or by adding calcium chloride solution, an excess of the precipitant being avoided in either case. The small amount of acid potassium tartrate purposely left in the liquid, when treating the latter with milk of lime, is decomposed with pure precipitated calcium carbonate. The object of not adding the milk of lime to the neutral point or in excess is to avoid the precipitation of iron or aluminum oxides. The solution must still remain perceptibly acid after the addition of the calcium carbonate. When cooled to about 40° C., the liquid is filtered with the aid of a suction pump, and the residue washed with water.

In the oldest methods of obtaining calcium tartrate from wine lees the latter were boiled with water and hydrochloric acid, the clear solution removed, and the residue treated with more water. As the extraction was very incomplete, these methods have not been employed of late years. When filtration of the lees was first attempted it was found that the pores of the filter became clogged, and that even under a pressure of four or five atmospheres no liquid would pass through. This difficulty was overcome by the process of Dietrich and Schnitzer, in which the albuminoid substances are coagulated by heating for about six hours under a pressure of four or five atmospheres. Wet lees, when thus treated, can be readily filtered. Dried lees are crushed, stirred in a tank with water, and heated by steam for some time, until air is completely expelled, before being heated in the pressure boiler.

During the process of heating the lees, the steam passing from the apparatus carries with it volatile empyreumatic products derived from the decomposed albuminoids. These have a very offensive odor, and should be conveyed into a factory chimney of sufficient height, so that the evil-smelling vapors are drawn up and decomposed by the furnace gases.

When the heating is finished, the steam outlet pipe is opened and the pressure allowed to fall to from one to one-half atmosphere, this pressure being required to force the lees from the boiler into a tank, which may be suitably constructed of wood. Here they are mixed with water, which has previously been put into the tank, and the requisite quantity of crude hydrochloric acid (21° to 22° B.). Experience has shown that for every 100 parts by weight of argol in the lees 100 parts of acid are required. Too little acid causes deposition of argol in the cloths of the filter-press, while too much destroys the cloths, and more lime is needed to neutralize the filtrate. If the conditions are right, the filtered liquid should have a specific gravity of about 6° B.

The acidified lees are pressed and washed, the washings being used instead of clear water for mixing with the next charge of lees from the pressure boiler. The tartaric acid in the filtrate is precipitated with lime and calcium carbonate, and the remainder of the process is the same as in the case of the argol, with the exception that there is no necessity to add calcium chloride or calcium sulphate.

Calcium tartrate obtained from wine lees is of a clear gray color, which is considerably purer than the dark gray or dark brown product from argol.

L. H. Baekeland patented, in 1916, a synthetic method for the production of tartaric acid: From carbon monoxide and an alkali is obtained an alkaline formate; this is changed into an oxalate by heating under pressure; the latter to glyoxalate by potassium amalgam in the presence of an acid. The glyoxalate is reduced electrolytically to tartaric (racemic) acid.

Oscar Ficinus, of Bensheim, proposed the following process to procure a pure tartaric acid.

Saturate the crude tartar with calcium carbonate, and decompose the resulting calcium tartrate with solution of zinc chloride, whereby calcium chloride and zinc tartrate are produced. The latter is almost insoluble, and is completely decomposed by hydrogen sulphide. The liquid filtered from the precipitated zinc sulphide, containing tartaric and sulphydric acids in solution, is heated for some time to 60° to 80° C., in order to dissipate the latter acid, filtered from the precipitated sulphur, and concentrated to the point of crystallization. (*A. Pharm.*, 1879.)

Description and Physical Properties.—"Colorless, translucent crystals, or a white, granular or fine powder. It is odorless, has an acid taste, and is stable in the air. One Gm. of Tartaric Acid is soluble in 0.75 cc. of water and in 3 cc. of alcohol, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water. The Acid is almost insoluble in chloroform and only slightly soluble in ether.

"When slowly ignited, Tartaric Acid gradually decomposes, emitting an odor resembling that of burning sugar (*difference from citric acid*). An aqueous solution of Tartaric Acid is acid to litmus paper and responds to the reactions for tartrates.

"Ash: not more than 0.05 per cent. Nearly neutralize 10 cc. of an aqueous solution of the Acid (1 in 10) with ammonia T.S., and add 10 cc. of calcium sulphate T.S.: no turbidity is produced (*oxalate*). The addition of 1 cc. of barium chloride T.S. to 10 cc. of an aqueous solution of the Acid (1 in 100), to which 3 drops of hydrochloric acid have previously been added, causes no turbidity (*sulphate*). A 10 cc. portion of an aqueous solution of the Acid (1 in 50) mixed with 0.5 cc. of hydrochloric acid meets the requirements of the test for *heavy metals.* Dissolve 10 Gm. of Tartaric Acid in 20 cc. of distilled water, add 2 cc. of sulphurous acid T.S., and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the precipitate formed is redissolved and the solution has a slight odor of ammonia. Cool, transfer the solution to a 50 cc. graduated cylinder, dilute with sufficient distilled water to measure 50 cc., and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not darker than the color of a control solution prepared as follows: Dissolve 2 Gm. of reagent ammonium chloride, in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S., and stronger ammonia water, as directed above; transfer the mixture to another 50 cc. cylinder, dilute it with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia. The two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*).

"**Assay.**—Proceed as directed under the assay for acids, using about 3 Gm. of Tartaric Acid and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.07504 Gm. of $C_2H_2(OH)_2(COOH)_2$." *U. S.*

"Soluble in less than 1 part of *water,* and in 3 parts of *alcohol* (90 per cent.). Yields, when neutralised, the *reactions* characteristic of tartrates. An aqueous solution is dextrorotatory. 1 gramme dissolved in *water* requires for neutralisation not less than 13.2 millilitres of *N/1 solution of sodium hydroxide.* Yields no characteristic *reactions* for copper, iron, or oxalates, and not more than the slightest *reactions* for calcium. *Lead limit* 20 parts per million. *Arsenic limit* 1.4 parts per million. 1 gramme dissolved in 50 millilitres of *water,* on addition of 0.5 millilitre of *solution of barium chloride,* does not yield a greater opalescence than 1 millilitre of *N/100 solution of sulphuric acid* when precipitated under the same conditions (limit of sulphates). Ash not more than 0.1 per cent." *Br.*

The powder is sometimes directed to be kept in well-stoppered vials; but Otto has shown that this method tends to spoil it. A better plan is to keep the powder in ordinary boxes. The tendency of the powder to form hard masses on keeping has been largely obviated of late years. This was formerly due to the presence of traces of sulphuric acid which caused the absorption from the air of water, but with the greater purity of the commercial product and absence of sulphuric acid the powder retains it pulverulent form much better than formerly.

Denigés gives the following modification of Mohler's test for tartaric acid. A solution of 2 Gm. of resorcinol in sufficient diluted sulphuric acid (1 per cent.) is added to 20 times its volume of strong sulphuric acid. In the presence of tartaric acid this liquid gives with a few drops of the fluid to be tested (which must be free from carbohydrates) a characteristic violet-red color when the mixture is heated to 115° to 140° C. (*Am. Drug.*, 1896, 182.)

Modifications of Tartaric Acid.—Five distinct modifications of tartaric acid exist. Their chief physical and chemical differences are:

a. Dextro-tartaric acid, or ordinary tartaric acid, forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *right.* The crystals fuse at 135° C., have a sp. gr. of 1.74 to 1.75, and are readily soluble in absolute and aqueous alcohol.

b. Lævo-tartaric acid forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *left.*

c. Racemic or *para-tartaric* acid forms hydrated, holohedral, triclinic crystals of $H_2C_4H_4$-

$O_6 + H_2O$, which are optically *inactive.* The crystals have a sp. gr. of 1.69, and are soluble in five parts of cold water and with difficulty in cold alcohol. The calcium racemate is less soluble in water than calcium dextro-tartrate, and is also distinguished by its insolubility in acetic acid and in ammonium chloride solution. Racemic acid can be prepared by mixing *d-* and *l*-tartaric acids, and can be resolved into them by appropriate methods. Racemic acid exists naturally in small proportion in the juice of grapes growing in particular localities, and was first obtained artificially in 1853 by Pasteur.

d. Inactive or *meso-tartaric* acid, optically inactive, but not resolvable in to *a* and *b* acids.

Uses.—Tartaric acid is sometimes used for citric acid in the preparation of refrigerant drinks, especially for decomposing sodium bicarbonate in the preparation of effervescent salts. It differs sharply from citric, acetic, and many other vegetable acids in that it is not oxidized in the system, appearing in the urine unchanged. Acid tartrates, therefore, tend to increase the acidity of the system. Tartaric acid is also more irritant than citric acid and decidedly more laxative in effects.

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassium, with which it produces a crystalline precipitate of bitartrate, and with the salts of calcium and lead, with which it also forms precipitates.

Dose, five to thirty grains (0.32–2.0 Gm.).

ACIDUM TRICHLORACETICUM. U. S.

TRICHLORACETIC ACID Acid. Trichloracet.

"Trichloracetic Acid, dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $CCl_3.COOH$." *U. S.*

Acide trichloracétique, *Fr.;* Acidum trichloraceticum; *P. G.;* Trichloressigsäure, *G.*

Three forms of chloracetic acid are known, mono-, di-, and tri-chloracetic acids, having the following formulas, respectively, $C_2H_3ClO_2$, $C_2H_2Cl_2O_2$, and $C_2HCl_3O_2$. *Monochloracetic acid* may be prepared by acting upon glacial acetic acid containing 10 per cent. of iodine with dry chlorine, reserving the portion distilling over between 180° C. and 188° C. *Dichloracetic acid* distils over between 189° and 191° C. *Trichloracetic acid,* discovered by Dumas in 1838, may be most conveniently prepared by treating hydrated chloral with three times its volume of fuming nitric acid, and placing the whole mixture in the sunlight until the red fumes have disappeared; the liquid is then distilled, and the portion coming over at 195° C. is pure trichloracetic acid. They form various salts, most of which are easily soluble in water. The mono- and tri- acids are solid, crystalline, deliquescent bodies; dichloracetic acid is a colorless liquid having a suffocating odor, and crystallizing at 0° C.

While trichloracetic acid is usually formed by the oxidation of hydrated chloral with nitric acid, it may also be obtained by the action of potassium permanganate in concentrated solution upon hydrated chloral, the potassium trichloracetate crystallizing out in white silky crystals. The reduction of trichloracetic acid to acetic acid can be accomplished by the use of nascent hydrogen.

Description and Physical Properties.—Deliquescent crystals having a slight, characteristic odor. One Gm. of Trichloracetic Acid is soluble in about 0.1 cc. of water at 25° C. It is very soluble in alcohol and in ether.

"Trichloracetic Acid heated with a solution of an alkali hydroxide is decomposed with the formation of alkali carbonate and chloroform, the latter being recognizable by the odor of phenylisocyanide (a poisonous substance), when a few drops of a saturated, aqueous solution of aniline are added to the heated mixture.

"Ash: not more than 0.05 per cent. Dissolve about 0.5 Gm. of ferrous sulphate in 5 cc. of an aqueous solution of Trichloracetic Acid (1 in 20), and superimpose it upon 5 cc. of sulphuric acid: no brownish-red color develops at the zone of contact (*nitric acid*). One Gm. of Trichloracetic Acid shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid.

"**Assay.**—Proceed as directed under the assay for acids, using about 4 Gm. of the Acid, previously dried to constant weight over sulphuric acid, and phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.1634 Gm. of $CCl_3.COOH$. Each Gm. of Trichloracetic Acid, previously dried to constant weight over sulphuric acid, corresponds to not less than 6.06 cc. and to not more than 6.12 cc. of normal sodium hydroxide.

"Preserve in well-stoppered bottles, in a cool place, protected from light." *U. S.*

Uses.—In dilute solution (1 per cent. or less) trichloracetic acid is strongly astringent and has been used as a local application in *hyperhydrosis* and congestion of the mucous membranes. In concentrated form it destroys vitality of tissue through its active precipitation of protein and also has the power of dissolving keratin. This combination of properties makes it a valuable caustic, especially in the treatment of various forms of keratosis such as *warts, moles,* etc. It has also been used as a caustic in vascular *naevi, chancroids, lupus,* etc. Its caustic action is accompanied with relatively little pain and it leaves a white leathery eschar. Gallaher (*Laryngoscope,* 1918, xxviii, p. 551) has highly praised it as a local application in *Vincent's angina.*

As an astringent trichloracetic acid may be applied in strengths of from 1/10 to 1 per cent. When used as a caustic a few drops of water may be added to the crystals to liquefy them and this solution applied by means of a glass rod, the surrounding parts being protected with vaseline or collodion. When the caustic has penetrated deeply enough the parts should be washed with a solution of carbonate of soda. It is also actively antiseptic and is used in diluted solution, 1 in 1000 to 1 in 2000, in *ozena* and other forms of chronic *inflammation of the nose, pharynx* and *tonsils.*

ACONITINA. U. S., Br.

ACONITINE Aconitin.

"An alkaloid [$C_{34}H_{47}O_{11}N$] obtained from aconite. Aconitine, administered subcutaneously to guinea pigs, has a minimum lethal dose of not less than 0.00,000,005,5 Gm. and not more than 0.00,000,006,5 Gm. for each gram of body weight of guinea pig." *U. S.* "Aconitine, $C_{34}H_{45}NO_{11}$, is an alkaloid obtained from Aconite Root." *Br.*

Aconitia, Aconitinum, Aconitin, Aconitine, *Fr. Cod.;* Aconitin, *G.;* Aconitina, *It., Sp.*

Formerly a process for the manufacture of aconitine was given in the U. S. and Br. Pharmacopœias, but is no longer given by either authority.

Crystallized aconitine was first made known by the researches of Groves (*P. J.,* 2d ser., viii, 121), but it was elaborately studied by Duquesnel. The methods of obtaining it differ, but, according to Patrouillard (*J. P. C.,* 4e sér., xix, 151), that of Duquesnel gives much the larger yield. It is as follows: 100 parts of the powdered roots having been mixed with one part of tartaric acid, and the whole exhausted by repeated percolation with cold alcohol, the liquid is evaporated at a low temperature on a water bath to the consistence of a fluidextract. To this, distilled water is added, and the precipitated resinous and oily matters removed by filtration. The solution of aconitine tartrate is then precipitated with a slight excess of potassium bicarbonate, agitated with washed ether, and the two fluids separated with a siphon. The ethereal solution is shaken four or five times with a 10 per cent. solution of hydrochloric acid, which takes up the alkaloids from the ethereal solution. The acid liquids are treated with calcium carbonate to saturation in order to prevent the prolonged and injurious action of the acid upon the crystallizable aconitine, the mixture is evaporated at a very gentle heat, filtered, and while still warm mixed with a solution of sodium nitrate (2 of salt to 3 of water) having the same temperature. The whole is allowed to cool slowly during several hours, and set away for several days' rest, when the crystals separate out as a crust on the bottom.

Pure aconitine may exist in an amorphous or in a crystalline form. The official product is always crystalline, but of amorphous aconitine there are two varieties, the hydrated and the anhydrous. When the alkaloid is dried at ordinary temperature, it retains 20 (Hager) or 25 (Hottot) per cent. of water; but when dried at the temperature of the water bath, it is anhydrous, and is then *not* soluble in 50 parts of boiling water. (Hager, *A. J. P.,* xlvii, 210.) For Hottot's process of preparing aconitine, see 15th ed., U. S. D.

The amorphous aconitine of commerce is of very uncertain composition and value, and should never be substituted for official aconitine. The official aconitine, however, of the Pharmacopœia is not pure aconitine of the chemist, but is a more or less variable mixture of the alkaloids of aconite. As these individual alkaloids differ greatly in their toxicity, it is obvious that aconitine will vary in its power almost as widely as aconite itself.

Description and Physical Properties.—"Colorless or white crystals. It is odorless, and is stable in the air. *Caution—Aconitine is extremely poisonous.* Aconitine is very slightly soluble in water. One Gm. dissolves in 28 cc. of alcohol, in about 65 cc. of ether, and in 7 cc. of benzene, at 25° C. It is almost insoluble in petroleum benzin.

"Aconitine melts at about 195° C. when heated rapidly. Solutions of Aconitine in neutral solvents are slightly alkaline to litmus paper. About 0.001 Gm. of Aconitine mixed with 2 or 3 drops of nitric or sulphuric acid on a white porcelain surface dissolves without coloration. Under the same conditions, 0.001 Gm. of Aconitine mixed with 2 drops of sulphuric acid containing 0.005 Gm. of ammonium vanadate in each cc. produces an orange color. Dilute solutions of Aconitine salts yield precipitates with mercuric potassium iodide T.S., tannic acid T.S., and gold chloride T.S., but only concentrated solutions yield precipitates with platinic chloride T.S., mercuric chloride T.S., and trinitrophenol T.S.

"The ash from 0.05 Gm. is negligible. Evaporate to dryness on a water bath about 0.01 Gm. of Aconitine with 5 drops of fuming nitric acid, cool, and treat the resulting yellow residue with alcoholic potassium hydroxide T.S.: no violet color develops (*pseudaconitine or atropine*).

"**Assay.**—Dissolve the Aconitine in distilled water with the aid of a little acetic acid and proceed as directed under *Tinctura Aconiti.*

"Preserve in well-closed containers, protected from light." *U. S.*

Aconitine as defined by the Br. Pharmacopœia is in "colorless, transparent, hexagonal crystals belonging to the rhombic system, prismatic and tabular. Melting point 198° C., at which temperature evolution of acetic acid occurs. Almost insoluble in *water, petroleum spirit,* and *carbon disulphide;* readily soluble in *benzene* and in *chloroform,* less readily in *ether* and in *absolute alcohol.* Forms a crystalline hydrochloride which melts at 149° C. A drop of an aqueous solution (1 in 10,000) placed upon the tongue produces a characteristic tingling and numbing sensation. An aqueous solution, not more dilute than 1 in 4000, faintly acidified with *acetic acid,* yields a reddish precipitate on the addition of a few drops of *N/10 solution of potassium permanganate.* The ethereal solution obtained by boiling Aconitine with *N/2 alcoholic solution of potassium hydroxide,* removing most of the alcohol by evaporation, diluting with *water,* acidifying, and extracting with *ether,* leaves on evaporation a crystalline residue of benzoic acid. When 0.0002 gramme of Aconitine is gently warmed with 4 drops of *sulphuric acid* an odor of benzoic acid is evolved, and if after five minutes a few crystals of *resorcin* are added and the heat continued, a reddish-yellow color, changing to intense red, is produced. No appreciable ash." *Br.*

Aconitine is precipitated from its solution by caustic alkalies, but not by ammonium carbonate or potassium and sodium bicarbonates. A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength as found in commerce.

Monti proposes a color test for aconitine with resorcinol which is now official in the Br. Pharm., 1914, after some modification. (See *P. J.,* 1908, 596.)

For E. R. Squibb's physiological test for aconitine and aconite preparations, see under *tinctura aconitum.* Its only peculiar color reaction is obtained with difficulty by dissolving in diluted phosphoric acid and evaporating, when at a certain degree of concentration a violet coloration appears.

Uses.—Aconitine produces effects on the system similar to aconite. Because of its extreme toxicity, as well as its variability, its use is not to be encouraged.

Dose, one eight-hundredth to one four-hundredth of a grain (0.000075–0.00015 Gm.).

Off. Prep—Unguentum Aconitinæ, *Br.;* Oleatum Aconitinæ, *N. F.*

ACONITUM. U. S. (Br.)

ACONITE Aconit. [Monkshood Aconite Root Aconiti tuber P. I.]

"Aconite is the dried tuberous root of *Aconitum Napellus* Linné (Fam. *Ranunculaceæ*). Aconite, in the form of the tincture, administered subcutaneously to guinea pigs, has a minimum lethal dose not exceeding 0.004 cc. of tincture for each gram of body weight of guinea pig. Aconite contains not more than 5 per cent. of its stems or 2 per cent. of other foreign organic matter." *U. S.*

"Aconite Root is the dried root of Aconitum Napellus, *Linn.*" *Br.*

Aconiti Radix, *Br.;* Aconite Root, Monkshood, Wolfsbane, Wolfroot, Friar's cap, Cuckoo's cap, Blue rocket; Racine d'Aconite, Aconit, Coqueluchon, Aconit Napel, *Fr.;* Tubera Aconiti, *P. G.;* Eisenhut, Eisenhutknollen, Sturmhut, Mönchskappe, Akonitknollen, *G.;* Aconito, *It., Sp.*

The name Aconite is derived, according to Pliny, from the Black Sea port, Aconie. While the drug was used by the ancient Chinese as well as by the hill tribes of India, it was introduced into modern medicine by Störck, of Vienna, in 1763. The genus *Aconitum* is a relatively large one, there being some sixty well-defined species, nearly half of which have been used in medicine. The species which is official and recognized by nearly all the Pharmacopœias is *Aconitum Napellus.* It is indigenous to the mountainous regions of Middle Europe and is found growing in Northern Europe, Siberia and Central Asia. It is extensively cultivated in temperate climates for its foliage and flowers and has been successfully grown in the testing garden of the U. S. Department of Agriculture. Schneider reports that it has become naturalized to some extent in California. There are five species of Aconitum which are indigenous to the mountainous regions of the Northern United States, two of these being found in the Rocky Mountains and on the Pacific Coast. Holm describes the morphology and structural characteristics of the wild Monkshood of the United States, *A. uncinatum* L., in *Merck's Rep.,* 1907, p. 65.

The roots or rhizomes of several other species of Aconitum are found in commerce, these being chiefly used in the manufacture of the alkaloids. (1) The tuberous roots of *A. variegatum* L. and of *A. Stoerkianum* Reich, are sometimes found in the commercial drug. These are smaller, not so pungent, although quite active. (2) Japanese Aconite is derived from *A. Fischeri* Reich. and *A. uncinatum* L. var. *japonicum* Regel. The roots are light to dark gray or brownish in color, fleshy, being smaller than the official tubers. They have a more or less circular cambium and the starch grains are more numerous than in the official root. They are largely imported into Europe and to some extent to this country. (3) Indian Aconite is derived from *A. ferox* Wall., a plant growing in the Himalayas and in Nepal. The roots are from 5 to 10 cm. long and from 2 to 4 cm. in diameter, being externally grayish-brown and deeply furrowed. They are hard, the fracture being horny or mealy and the inner surface is either yellowish-brown or whitish. The cambium is 7- to 9-rayed and the taste resembles that of the official Aconite. (4) Another species of Aconitum that is very poisonous is *A. Lycoctonum* L., of Europe and Northern Asia. This, however, does not produce a tuberous root, but develops an oblique rhizome surrounded with numerous roots. (5) The fleshy roots of *A. heterophyllum* Wallich., a plant growing in the West Himalayas, are somewhat ovoid and flattened at the summit and base. Externally they are grayish-brown. The odor resembles that of black pepper and the taste is bitter and acrid. The rhizome contains an amorphous bitter alkaloid, *atisine,* which is not toxic. Under the name of *Nepaul aconite* there enters European commerce the roots of species of aconite grown in India. It is by some believed that these are identical with those roots known in India as "Bikh" or "Bish," the latter apparently being derived from the *A. spicatum* Lam. Under the name of *Utees, Atees,* or *Atis,* the rhizome and roots of *A. heterophyllum* are said to be largely employed in doses of 20 grains as an antiperiodic. *Wakhma* is the root of *A. Palmatum* Don, in which Jowett found *aconitic acid* and the alkaloid *atisine,* $C_{22}H_{33}NO_3$, which, according to Cash, is physiologically very feeble. (*J. Chem. S.,* 1896.) While most of the species of *Aconitum* are more or less closely related in their physiological effects, the use of other species in medicine, even for the purpose of extracting alkaloids, is to be condemned. According to Fraser (*P. J.,* 1917, xcviii, 209) the various aconites may be divided into two classes, those in which aconitine is the prevailing alkaloid and those in which pseudo-aconitine predominates; since these two alkaloids are not identical in their effects it follows that the alkaloids obtained from unofficial species may exercise a different effect from the official aconitine.

Aconitum Napellus is a perennial herbaceous plant, with a fusiform to conical tuberous root, seldom exceeding 10 cm. in length and 2 cm. in thickness near the summit, brownish externally, whitish and fleshy within, and sending forth numerous long, thick, fleshy rootlets. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown, fusiform, wrinkled, and supports the stem, while the younger of a light yellowish-brown color and conical shape is destined to furnish the stem of the following year, the old root decaying. The stem is erect, round, smooth, leafy, usually simple, and from two to six or even eight feet high. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisions. The divisions are wedge-form, with two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniæ or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue color, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. There are 2 lanceolate bracts beneath each pedicelled flower. The sepals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two to eight hammer-like petals, the 2 posterior ones being nectariferous and covered by the hood of the posterior sepal. The carpels are 3 to 4 with bilobed stigma.

The fruit consists of three to four beaked follicles. The seeds are angular, wrinkled and very acrid. They rapidly lose their germinating power upon drying and storing and are for the greater part non-viable after a year.

This plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental plant. All parts of the plant are acrid and poisonous. The leaves and root are used. The leaves should be collected when the flowers begin to appear, or shortly before. After the fruit has formed, they are less efficacious. The *fresh leaves* have a faint narcotic odor, most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning and acrid, with a feeling of numbness and tingling, on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The *dried leaves* have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. The root is much more active than the leaves, and an extract from the latter is said to have only one-twentieth of the strength of one made from the former. It should be gathered in autumn or winter after the leaves have fallen, and is not perfect until the second year. It has been mistakenly substituted for horseradish root, as a condiment, with fatal effects. The wild plant is said to be more active than the cultivated. (Schroff.) The studies of P. W. Squire seem to show that in the autumn the root is the most active. So far, however, as concerns the whole plant, the practical difficulty is that the root of *A. paniculatum* Lam. cannot be distinguished by the ordinary collector from that of *A. Napellus,* except by taste; so that the custom which seems to prevail of gathering the root about the flowering period is probably well founded. The plant is being cultivated to some extent for medicinal purposes in England, but much of the stock is of doubtful nature, owing to the extraordinary tendency of *A. Napellus* to hybridize with other species and to alter under cultivation. (See *P. J.,* 1889, 645.) For Keller's test for aconite root and leaves, see *Proc. A. Ph. A.,* 1895, 539.

Aconite root is collected chiefly from plants growing wild in the cool mountainous regions of Germany, Switzerland, Spain and France. The tuberous roots are dug up in autumn, washed and carefully dried. The present commercial supplies coming to the United States are shipped chiefly from Trieste, Hamburg, Leghorn, Barcelona and Marseilles.

A number of substitutes and adulterants for official aconite root have appeared in commerce within recent years. Chief among these have been the roots of *Aconitum Fischeri* Reichb., *A. chasmanthum* Stapf. and *A. Laciniatum* Stapf.

The root of *A. Fischeri* Reichb., commonly known as *"Japanese Aconite"* has been a very common article of commerce. It is smaller than the official aconite for which it has been substituted, and may be further distinguished from the genuine article by its lighter weight, short conical shape generally more mealy interior and usually dark greyish; less deeply wrinkled exterior. Cross sections exhibit a less pronounced stellate cambium and more numerous fibro-vascular bundles arranged in a wavy circle.

The root of *A. chasmanthum* Stapf. is generally smaller than the official article, about 2 cm. long and about 0.75 cm. in diameter, less wrinkled with rootlet stubs usually clustered at the basal end. It contains *indacinatine.*

The root of *A. laciniatum* Stapf., commonly known as "*Nepaul Aconite*" or to the natives of India as "*Bikh*" or "*Bish Aconite*" is larger than that of *A. napellus,* being up to 15 cm. in length and 4 cm. in diameter near the crown; it is fusiform to irregularly cylindrical in shape, coarsely wrinkled and brown externally, usually yellowish and horny internally, showing gelatinized starch when scrapings are examined under the microscope. It contains *pseudaconitine.*

Commercial aconite root shows considerable variation and is usually a mixture of six or seven different kinds of tubers, as follows: 1. Single fleshy tubers which are smooth, light brown and full of starch. 2. Single tubers which are single, somewhat elongated fusiform, crowned with short stems, dark brown and longitudinally furrowed. 3. Twin tubers, one of which is bud-crowned and the other having a short stem at the summit. 4. Very small single tubers usually crowned with stems, the lower portion being acute or pointed. 5. Single tubers which are almost cylindrical, crowned with stems and either fleshy and nearly smooth or more or less shrunken and furrowed. 6. Dark brown resinous tubers. 7. And finally fragments of small and nearly filiform roots.

The *root* has a feeble earthy odor. Though sweetish at first, it has afterwards the same effect as the leaves upon the mouth and fauces. It shrinks much in drying, and becomes darker, but does not lose its acridity.

Description and Physical Properties.—"*Unground Aconite.*—More or less conical or fusiform, from 4 to 10 cm. in length, and from 1 to 3.5 cm. in diameter at the crown; externally dark brown or grayish-brown, smooth or longitudinally wrinkled, the upper end with a bud, or remains of bud-scales and a stem-scar, the other portions with numerous root-scars or short rootlets; fracture short, horny or somewhat mealy; internally whitish, light brown, or dark brown; bark, 1 to 2 mm. in thickness, cambium zone usually 5- to 8-angled; odor very slight; taste sweetish, soon becoming acrid and developing a tingling sensation, followed by numbness. (*Taste cautiously.*)

"*Structure.*—An outer layer of one or more rows of suberized cells with blackish-brown walls; a primary cortex of parenchyma and characteristic stone cells, separated by a modified endodermis from an inner layer of starch-bearing parenchyma interspersed with a few small vascular bundles; in the cambium zone a 2- to 4-rayed collateral vascular bundle at each angle or a number of small bundles in an irregular circle; pith of large starch-bearing parenchyma cells.

"*Powdered Aconite.*—Grayish-brown; starch grains numerous, spherical, somewhat planoconvex, single, or 2- to 5-compound, the individual grains from 0.003 to 0.020 mm. in diameter and frequently with a central cleft; tracheæ mostly with slit-like, simple pores, sometimes with spiral or reticulate thickenings or with bordered pores; stone cells single, or in small groups, tabular, irregular, rectangular or elongated in shape, from 0.1 to 0.4 mm. in length, walls strongly lignified and having large simple pores; a few fragments of cells with brownish walls; fragments of parenchyma numerous, the cells being filled with starch grains; bast-fibres from stems few, very long, with lignified walls and marked by transverse or oblique, slit-like pores.

"**Assay.**—Prepare a tincture by the official process, and assay as directed under *Tinctura Aconiti.*" *U. S.*

The following standards for aconite root are given in the British Pharmacopœia: "From four to ten centimetres long, and from one to two centimetres wide at the upper extremity. Conical, dark brown, with numerous root scars, and crowned with base of the stem or the remains of a bud. Internally solid and starchy. In transverse section a stellate cambium with small vascular bundles at the projecting angles; primary cortex narrow, with isolated thick-walled sclerenchymatous cells; cells of parenchymatous tissue contain numerous small simple or compound starch grains. No marked odor; taste at first slight, followed by persistent sensation of tingling and numbness." *Br.*

The British Pharmacopœia formerly recognized the flowering tops of the Aconite (*Aconiti Folia*). To be effective they should be collected just as the flowers are beginning to expand, at which time they are richest in alkaloid. The dried leaves are stated to contain about 0.3 per cent. and the flower-buds about 0.4 per cent. of aconitine. For an account of the chemistry of aconite, see *Aconitina.*

Chemical Assay.—According to Roth (*J. A. Ph. A.,* 1913, ii, p. 705) the chemical assay of aconite does not offer any measure of its activity; and Haskell (*Am. Drug.,* 1916, lxiv, 129) asserts that the chemical aconitine assay is not only useless but dangerously misleading. The U. S. has therefore, entirely omitted the chemical standard but it is still recognized by the Br. Probably the most satisfactory test yet devised is the toxicity of the guinea pig, as recommended by the U. S. P. X. Even this is far from satisfactory, as according to Dohme (*Proc. Amer. Drug. Man. Assoc.,* 1919) the fatal dose may range from 66 to 133 per cent. of standard in the hands of different experimenters. The chemical assay recommended by the Br. is as follows:

"Yields not less than 0.40 per cent. of ether-soluble alkaloids when assayed by the following process, provided with a glass tap and suitably plugged with cotton wool, introduce 10 grammes of Aconite Root in No. 40 powder and 75 millilitres of *alcohol* (70 per cent.). Macerate for four hours, shaking occasionally. Then allow percolation to proceed slowly until the liquid ceases to drop. Continue the percolation by the addition of more of the same menstruum until 150 millilitres have been collected or the Root is exhausted. Evaporate the percolate to dryness in a shallow porcelain evaporating basin, at a temperature not exceeding 60° C. Dissolve the residue in 5 millilitres of *N/10 solution of sulphuric acid* diluted with 20 millilitres of *water*. Filter into a separating funnel, washing the dish and filter with about 30 millilitres of *water*. Add to the mixed filtrate and washings 25 millilitres of *ether* and 2 millilitres of *solution of ammonia*, and shake for one minute. After separation draw off the lower layer into a flask, and filter the ethereal solution into a beaker. Return the contents of the flask to the separator, add 20 millilitres of *ether* and again shake for one minute, separating the aqueous liquid and filtering the ethereal solution into the beaker. Repeat the operation with two other portions, each of 20 millilitres, of *ether*. Evaporate the mixed ethereal solutions to dryness, dry the residue at 60° C., dissolve it in 5 millilitres of *N/20 solution of sulphuric acid* diluted with 20 millilitres of *water*, and titrate back with *N/20 solution of sodium hydroxide*, *tincture of cochineal* being used as indicator. Deduct the number of millilitres of the alkaline solution required from 5, multiply the difference by 0.3217; the result will be the percentage of ether-soluble alkaloids in the powdered Root." *Br.*

Constituents.—Our present knowledge of the chemistry of aconite is based chiefly on the investigations of Dunstan (*Tr. Chem. Soc.*, 1892, lxi, p. 285 and 1905, lxxxvii, p. 1622; *P. J.*, 1893, p. 625), Schulze (*A. Pharm.*, 1906, ccxliv, p. 169 and 1916, ccliv, p. 567), Wright (*J. Chem. S.*, 1875, xxix and 1879, xxxv, p. 387).

Aconitum Napellus contains at least three distinct alkaloids. The alkaloid *aconitine*, which was first separated in a pure state by Groves in 1860, is the most important of these principles. It has been assigned various formulæ; Wright gives $C_{33}H_{43}O_{12}N$; the U. S. accepts the formula of Freund and Beck, $C_{34}H_{47}O_{11}N$, but the Br. that of Schulze, $C_{34}H_{45}O_{11}N$. It has been shown that pure aconitine crystallizes in rhombic prisms, has a melting point of 197° to 198° C. and is dextrorotatory. When its solution is heated under pressure to a temperature of 120° C. it undergoes hydrolysis into benzoyl aconine and acetic acid. Subsequently the first of these bases is split up into benzoic acid and aconine.

Benzoyl-aconine (also called *benzaconine*) seems to be identical with *napelline* or *isaconitine*. Its formula is given by Schulze as $C_{32}H_{43}O_{10}N$, its melting point 130° C. It is amorphous but forms crystalline salts. It is dextrorotatory but furnishes laevorotary salts. It occurs naturally in aconite root or can be formed by hydrolysis from aconitine. Its toxicity is very much less than that of aconitine and it appears to differ somewhat in the type of its physiological action as well as in the degree.

Aconine is one of the final products of hydrolysis and also occurs naturally in aconite root. Dunstan gives its formula as $C_{26}H_{41}O_{11}$ but Schulze gives $C_{25}H_{39}O_9N$. Its melting point is 132° C. It is actively dextrorotatory but yields laevorotary salts. Neither it nor its salts have been crystallized because of their hygroscopic properties.

Picraconitine of Wright is probably a mixture.

Other species of aconitum yield allied but different alkaloids from the official. We shall list briefly the more important of these: *Aconitum ferox* Wall contains according to Wright the alkaloid *pseudaconitine*. The same alkaloid is found also in the Nepaul aconite whose exact botanical origin is somewhat doubtful. Its formula is $C_{36}H_{51}O_{12}N$. It hydrolyzes into acetic acid and veratroyl-pseudaconine. According to Cash and Dunstan (*Phil. Trans. Roy. Soc.*, 1902, cxcv, p. 39) it is more active than aconitine.

Of the two Japanese aconite roots the *A. uncinatum* contains, according to Wright, the alkaloid *japaconitine*. This is stated by Freund and Beck (*B. Chem. G.*, 1894, xxvii, p. 723) to be identical with aconitine, but Dunstan and Read (*Tr. Chem. Soc.*, 1900, lxxvii, p. 49) and Makoshi (*A. Pharm.*, 1909, ccxlvii, p. 242) maintain that, although closely allied to, it differs from aconitine. The *A. Fischeri* contains *jesaconitine*.

From *A. Lycoctonum*, Hübschman in 1866 obtained an alkaloid *lycoctonine*, but Dragendorf and Spohn (*J. P. C.*, 1884, x, p. 361) state that this is a decomposition product of *lycaconitine*. The latter authors also found myoctonine in this root.

Dustan and Andrews (*Tr. Chem. Soc.*, 1905, lxxxvii, p. 1636) found *bikhaconitine* in *A. Spicatum* and *indaconitine* in *A. chasmanthum*. *Aconitum septentrionale* contains *lappaconitine* (Schulze and Ulfert, *A. Pharm.*, 1922, clx, p. 230) and *septentrionaline* (Weidemann, *A. E. P. P.*, 1922, xcv, p. 136).

Uses.—Aconite was well known to the ancients as a powerful poison; it appears to have been used as an arrow poison early in Chinese history and perhaps also by the inhabitants of ancient Gaul. Although mentioned in the *Meddygon Myddfai*, published in Wales in the 12th century, it was introduced into regular medicine by Baron Störck of Vienna, whose experiments were published in the year 1762.

Locally aconite is actively irritant and also a paralyzant to the peripheral sensory nerves. When applied to a mucous surface it produces at first a burning tingling sensation followed in a few minutes by a numbness. This sensation may even be perceptible after the systemic ingestion of very large doses. When administered internally the most marked changes are seen in the circulation. The first effect is generally a slowing of the pulse due to stimulation of the cardio-inhibitory centers, with consequent fall in the blood pressure. After somewhat larger doses, however, there is a weakening of the force as well as reduction of the rate of the pulse brought about by a direct action on the heart muscles. After poisonous doses various irregularities of heart action are produced and often there will be complete lack of harmony between the contraction of the auricle and ventricle. After fatal doses the heart is arrested in complete diastole and will respond to neither electrical nor mechanical irritation. In the frog, large quantities of aconite produce a loss of reflex activity, which is apparently due to a paralysis of sensation as voluntary motion is preserved for some time later, although it too may eventually be abolished. The drug appears to affect both the sensory nerves and the receptive side of the spinal cord, although the latter is involved comparatively late in the poisoning. In mammals this depressant action upon the nervous system can scarcely be demonstrated because of the powerful depressant effect upon the circulation.

Aconite is used internally for the purpose of quieting overaction of the heart either due to essential diseases of the circulatory system or to various febrile complaints. For example, in certain cases of *valvular lesions* of the heart where, although the muscular compensation is apparently good, the pulse rate is abnormally rapid, apparently from loss of nerve control; and in the analogous condition of so-called *irritable heart,* seen in improperly trained athletes and military recruits and the like, in which despite the absence of any demonstrable organic lesion the heart rate tends to become very rapid on the slightest exertion aconite has long been a favorite remedy. Although its effects in these conditions are generally less certain than those of veratrum, because of its freedom from nauseating properties it is preferred by many clinicians. In cases of *high blood pressure* by slowing the pulse it will often lead to a sensible reduction in the arterial tension; it should be remembered in this connection, however, that there is no action upon the vasomotor center (see Pilcher and Sollmann, *J. P. Ex. T.,* 1915, vi, 366). Aconite has also been used in various mild *febrile conditions.* Whatever value it possesses in such states, however, must be ascribed to its action in preventing excessive rapidity of the heart or to a slight tendency towards the production of diaphoresis from slowing of the circulation.

Aconite is also frequently employed for its local effects. The combination of local irritant effects with anesthetic action suggests strongly its use in peripheral *neuralgias.* It must not be forgotten, however, that if used too freely for this purpose it may be absorbed through the skin in sufficient quantities to cause serious poisoning. It is also occasionally employed as a local anesthetic to the stomach in various types of *vomiting* or *gastralgia* but on account of its systemic effect is of secondary value.

For internal use the best preparation is the tincture which may be given in doses of from five to fifteen minims (0.3–0.9 cc.). For external application and fluidextract may be employed, but generally an ointment is preferred. This may be made by rubbing up the extract with two or three parts of lard, or the *ointment of aconitine* of the British Pharmacopœia may be used. The U. S., 1870, recognized a *plaster of aconite.*

Toxicology.—Aconite is a rapidly acting and powerful poison. The symptoms produced by overdose of it are sensations of warmth in the stomach, sometimes with nausea but usually without vomiting, with slowing of the pulse and of the respiration; the skin is cool and moist and there is profound prostration. As the poisoning progresses the respirations become more slow and shallow, the pulse more and more feeble and towards the end may become rapid or very irregular. A characteristic symptom, in fact the only symptom of diagnostic importance, is the peculiar numbness and tingling first felt in the lips and mouth, but later also often in the fingers. At times here is dimness of vision, the pupils may be either contracted or dilated, and occasionally delirium and stupor or convulsions may precede the fatal termination.

In the treatment of aconite poisoning the patient should be kept absolutely in a horizontal position or with the feet higher than the head. For the purpose of emptying the stomach the stomach pump is preferable to emetics as the latter involve a more or less serious strain upon circulation. Hartung (*A. E. P. P.,* 1912, lxix, 176) has shown experimentally the great value of atropine. Other circulatory stimulants such as strychnine, and ammonia, may also be used. Body temperature should be maintained by external application of heat.

Dose, of aconite root, one-half to one grain (0.032–0.065 Gm.).

LARD

"The purified internal fat of the abdomen of the hog (*Sus scrofa,* var. *domesticus* Gray, Fam. *Suidæ*)." *U. S.* "Prepared Lard is the purified internal fat of the hog, Sus scrofa, *Linn.*" *Br.*

Adeps Præparatus, *Br.;* Axungia Porci, s. Porcina, Axungia; Prepared Lard, Hog's Lard; Axonge, *Fr. Cod.;* Graisse, Graisse de Porc, Saindoux, *Fr.;* Adeps Suillus, *P. G.;* Schweineschmalz, *G.;* Grasso suino, Sugno, Grasso di Porco, Lardo, *It.;* Grasa de cerdo, Manteca de puerco, Lardo, *Sp.*

Preparation.—Lard is the prepared fat of the hog. The Br. Pharmacopœia (1898) gave a process for its preparation; but in this country it is generally purchased already prepared by the druggists. The adipose matter of the omentum and mesentery and that around the kidneys, are usually employed, though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all of which it must be freed before it is fit for use. For purification, the fat, having been deprived of membranous matter as far as possible by the hand, is cut into pieces, washed with water till the liquor ceases to be colored, and then, after carefully separating the water, it is melted in a copper or iron vessel, over a slow fire, or, on the large scale, by steam heat. The heat is continued until all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. This operation is technically known as "rendering." In the western packing houses this operation is performed upon a tremendous scale. The rendering tanks holding nearly 100,000 lbs. Care should be taken that the heat be not too great, as otherwise the lard may be partially decomposed, acquire a yellow color, and become acrid. The process is completed by straining the liquid through linen, and pouring it into suitable vessels, in which it hardens upon cooling. It has been suggested that for the complete removal of tissue the lard should be remelted over a water bath and then filtered through filter paper by means of a hot water funnel. Lard may be rendered inodorous by melting it, on a salt-water bath, with a little alum or common salt and continuing the heat until a scum rises which is skimmed off. The lard is then allowed to cool and the saline matter separated by washing it thoroughly with water. For a particiular account of the process, see *A. J. P.*, xxviii, 176.

Lard, as offered for sale, sometimes contains common salt, which renders it unfit for pharmaceutical purposes. This may be detected, when the quantity is insufficient to be sensible to the taste, by means of silver nitrate, which will produce a precipitate of silver chloride with water in which the salted lard has been boiled, after cooling and filtration. To free it from this impurity, it may be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated. Lard was formerly adulterated with water, starch, and a small portion of alum and quicklime, which rendered it whiter, but unfit for medicinal use. But by far the most common adulteration of lard in recent years is through the use of cotton seed stearin. Crookes (*Analyst*, 1893, p. 221) gives the following very delicate modification of Milliau's test. Pure white filtering paper is first moistened with 12 per cent. solution of silver nitrate and held over a small sample of the lard, which is gradually heated in an oil bath to 115.5° C., when, if even less than 1 per cent. of cottonseed oil is present, the paper will turn light brown to nearly black. Pure fresh lard does not affect the paper. The best test for detecting imitation lard is the Halphen test for cottonseed fat, see under *Oleum Olivæ.*

The food laws recognize both *compound lard* and *imitation lard.* The latter consists of beef stearin and cotton seed oil with no lard whatever present. The former must contain at least 50 per cent. of genuine hog fat. The *compound lard* is rarely seen at present but the *imitation lard* or *lard substitute* as it is also called is freely sold at a lower price than lard. The regulations regarding its sale require that it be plainly labeled so as to designate its character, but much of it is sold as pure lard by unscrupulous grocers.

It may be readily distinguished by applying the U. S. P. tests which detect cotton seed stearin and also by the crystallization test which enables beef stearin to be detected.

Lard from hogs which have been fed with cottonseed meal will not only show the tests for cottonseed oil (Becchi and Halphen tests), but even the presence of physosterin or vegetable cholesterin can be shown. (Emmett & Grindley, *J. Am. C. S.*, 1905, 270.)

The slight reaction shown under these conditions is not likely to be confused, however, with the marked reaction which occurs in a sample of lard which is actually adulterated, as has been shown in the examination of hundreds of samples in the enforcement of the food laws.

Although it is possible at this time to obtain lard of excellent quality in the American market, if due care is observed (Gordon, *Proc. Pa. Pharm. Assoc.*, 1901, 126), there are many grades of lard to be found in commerce, designated by the dealers as follows: 1. Neutral (or Kettle) lard. 2. Leaf lard; made by melting the whole flare with steam, followed by pressure. 3. Choice kettle-rendered lard, chiefly from fat from the back of the hog. 4. Prime steam lard, from all the fatty parts of the hog. 5. Butcher's lard, melted on an open fire. 6. Off grade lard, from salt fat. 7. Dead hog grease from diseased hogs. 8. Brown grease from the intestines. 9. White grease, from the other parts. 10. Yellow grease, from the waste of packing warehouses. 11. Pig's foot grease, from glue factories.

Description and Physical Properties.—"A soft, white, unctuous mass, having a faint odor, and a bland taste. It is free from rancidity. Lard is insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, and in petroleum benzin.

"Lard melts between 36° and 42° C., forming a clear liquid from which no aqueous layer separates. Distilled water boiled with lard shows no alkaline reactions to litmus paper (*alkalies*). Dissolve 10 Gm. of Lard in 30 cc. of chloroform, mix the solution with 10 cc. of neutralized alcohol, and add 1 drop of phenolphthalein T.S.: not more than 2 cc. of tenth-normal sodium hydroxide is required to produce a pink tint when shaken vigorously (*free fatty acids.*) Boil 1 Gm. of Lard with 20 cc. of alcohol under a reflux condenser for ten minutes, cool, filter, and add to the filtrate 5 drops of an alcoholic solution of silver nitrate (1 in 50): the turbidity, if any, is not greater than that produced by the same quantity of the silver nitrate solution in a mixture of the same volume of alcohol and 0.5 cc. of fiftieth-normal hydrochloric acid (*chloride*). Agitate in a test tube 5 cc. of melted and filtered Lard, while warm, with 5 cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 cc. of alcohol, and adding 2 drops of nitric acid), and heat this mixture for five minutes on a water bath: the liquid fat acquires no reddish or brown color, nor is any dark color produced at the line of contact of the hot liquids (*cottonseed fats*). Dissolve 5 Gm. of Lard in 20 cc. of ether in a test tube, close the tube loosely with purified cotton, and allow it to stand for about eighteen hours at a temperature of about 20° C. Collect some of the crystals which have separated at the bottom of the test tube, mount them either in alcohol or in a fixed oil, and examine under a microscope having a magnifying power of about two hundred diameters: lard stearin crystallizes in the form of flat, rhomboidal plates, cut off obliquely at one end and grouped irregularly. (Beef stearin crystallizes in the form of cylindrical rods or needles with sharp ends and grouped in fan-shaped clusters.) Saponification value: not less than 195 and not more than 203. Iodine value: not less than 46 and not more than 70.

"Preserve in a cool place, in well-closed containers which are impervious to fat." *U. S.*

"A soft, white, homogeneous, unctuous substance. Odor faint but not rancid. Entirely soluble in *ether*. *Acid value* not more than 1.2; *saponification value* 192 to 198; *iodine value* 52 to 63; *unsaponifiable matter* not more than 0.5 per cent.; *refractive index* at 60° C. 1.4530 to 1.4550. Forms on melting a clear liquid which does not deposit water on standing. *Water* boiled with it does not acquire an alkaline reaction (absence of alkalies), and, after filtering and acidifying with *nitric acid,* does not yield any reaction with *solution of silver nitrate* (absence of chlorides). When a mixture of 20 millilitres of the melted and filtered Lard with 10 millilitres of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute and allowed to stand, the acid layer does not become pink (absence of sesame oil). In India, Prepared Suet (Sevum Præparatum) should be employed in making the official preparations for which Prepared Lard is directed to be used." *Br.*

When melted, it readily unites with wax and resins. Like most animal fats and oils, it consists of stearin, palmitin, and olein its consistence, when pure, depending largely upon the relative proportions of these principles.

Lard oil, which was formerly recognized by the U. S. P. VIII under the name of *Oleum Adipis,* is made by exposing lard to low temperatures and then subjecting it to powerful pressure. In this way the stearin of the lard is separated from the olein, the latter oozing out from the presses in the form of a yellowish-white oil; the stearin left behind is found in the market in large cakes and is largely used in making soap. Lard oil is colorless or pale yellow liquid which, at a temperature below 10° C. begins to deposit a white granular fat and forms a solid white mass at approximately the temperature of freezing water. Its specific gravity is from 0.905 to 0.915; it shows a saponification value of 195 to 197 and an iodine value between 56 and 74. It is not pure olein but contains varying proportions of stearin and is sometimes adulterated with paraffin oil.

Olein may also be separated by means of boiling alcohol, which, on cooling, deposits the concrete principles of the lard.

Exposed to the air, lard absorbs oxygen and becomes rancid. It should, therefore, be kept in well-closed vessels, or procured fresh when wanted for use. In the rancid state, it irritates the skin, and sometimes exercises an injurious reaction on substances mixed with it. Rancidity in lard and other fats is prevented by digesting them with benzoin or poplar buds (see *Adeps Benzoinatus*), and rancid lard may often be greatly improved by washing it with lime water. (See *Unguenta.*) Lard even when fresh is slightly acid, as was proved by Dieterich. (*A. Pharm.,* 1887.)

Uses.—Lard is emollient, and is occasionaly employed by itself in frictions, or in connection with poultices to preserve their soft consistence; but its chief use in pharmacy is as an ingredient in the preparation of ointments and cerates. (See under *Unguenta.*)

Off. Prep.—Adeps Benzoinatus, *U. S.* (*Br.*).

ADEPS BENZOINATUS. U. S., (Br.)

BENZOINATED LARD Adeps Benz.

Adeps Benzoatus, *Br., P. G.;* Benzoated Lard; Ointment of Benzoin; Unguentum Benzoini, *U. S.* 1870; Axungia Balsamica, s. Benzoinata, s. Benzoata; Axonge (Graisse) benzoinée (balsamique), *Fr.;* Benzoinirtes Schmalz, Benzoeschmalz, *G.;* Grasso con benzoino, *It.*; Manteca benzoada, Manteca con benjui, *Sp.*

"Lard, 1000 Gm.; Siam Benzoin, in coarse powder, 10 Gm.; to make about 1000 Gm. Melt the lard on a water bath, add the benzoin, mix thoroughly, and continue the heat for two hours, covering the vessel and not allowing the temperature to rise above 60° C. Strain the liquid through muslin, and stir it occasionally while it cools. Preserve in a cool place, in well-closed containers which are impervious to fat.

"NOTE.—For use in southern latitudes and during the heated season in other localities, 50

Gm. of the lard (or more, if necessary) may be replaced by an equal weight of white wax." *U. S.*

"Prepared Lard, 1000 grammes; Benzoin, in coarse powder, 30 grammes. Melt the Lard, add the Benzoin, and maintain at a temperature of 60 C. for one hour, stirring frequently; strain, and stir until nearly cold. In India, Benzoated Suet (*Sevum Benzoatum*) should be employed in making the official preparations for which Benzoated Lard is directed to be used." *Br.*

That the balsamic or resinous principles, in certain substances like benzoin, exercise a valuable function in preserving fats has been proved by abundant experience. The present U. S. formula differs somewhat from the British in the amount of benzoin directed. The name "benzoinated lard" is preferred by the U. S. Pharmacopœia to that used by the British Pharmacopœia "benzoated lard" because benzoin is used as a preservative; the word benzoated might imply that a benzoate or benzoic acid is employed. A much pleasanter and agreeable product is insured by heeding the U. S. directions as to limiting the temperature, a high heat volatilizing the odorous principles and communicating an empyreumatic odor.

ADEPS LANÆ. U. S., Br.

WOOL FAT Adeps Lan. [Anhydrous Lanolin, Refined Wool Fat]

"The purified, anhydrous, fat-like substance from wool of sheep (*Ovis aries* Linné Fam. *Bovidæ*)." *U. S.* "Wool Fat is the purified fat of sheep's wool, freed from water." *Br.*

Anhydrous wool-fat, *E.;* Suint de laine, *Fr.;* Adeps Lanæ, anhydricus, *P. G.;* Wollfett, *G.;* Lanolinum Anhydricum.

Both the United States and the British Pharmacopœias now recognize wool fat (anhydrous) and hydrous wool fat.

Preparation.—The wool of sheep contains from 10 to 50 per cent. of its weight of fat, which must be removed before the wool can be used in the manufacture of woolen fabrics. The crude fat was termed *æsypus* and *æsypum* by the ancients but the modern name for it is *suint.* This fat is a mixture of *cholesterin,* $C_{26}H_{43}(OH)$, esters of the several fatty acids contained in ordinary fats. Darmstaedter and Lifscheitz obtained from the alkaline washings of partially saponified wool fat two unsaturated alcohols, $C_{10}H_{20}O$ and $C_{11}H_{22}O$, both being colorless, odorless and tasteless powders; *lanolin alcohol,* also a colorless, odorless powder, was isolated by G. Marchetti (*B. Chem. G.,* 1895, No. 19); by the action of chromium trioxide the latter is converted into *lanolinic acid,* $C_{12}H_{22}O_3$, a white crystalline powder. (*P. J.,* 1895, p. 75.) Wool fat may be obtained by treating the wool with petroleum benzin and distilling off the benzin. The objection to the latter process is the difficulty of getting rid of the benzin odor. Liebreich's patented process for obtaining it from the washings of wool is as follows: The fresh undecomposed waste liquor or lye is passed through a centrifugal machine, in which the dirt and fat are separated from each other, while the cleansed soap liquor is continually drawn off by means of a pipe and led directly into the vat which serves for the acidulation. The raw lanolin thus obtained is thoroughly kneaded by suitable machinery in cold flowing water until the water which flows off is as clear as the water which flows in. The raw lanolin is then heated with water, thereby it is split up into water and fat. The latter is skimmed off from the surface and cooled, and for further purification it can be treated in the centrifugal machine in a melted condition, or it can be dissolved in ether, ethylated or methylated spirits, or other solvents and the solution can be separated from the residue by filtration or other means. The solvents can be recovered by treatment in suitable stills. After the fat has been cleaned as above stated, it is thoroughly kneaded with water for a long time, and a perfectly white neutral ointment is obtained. From the deposit in the lowest part of the centrifugal machine a further portion of lanolin can be obtained by stirring the same with clean or salt water and again treating it in the centrifugal machine, or extracting it, either in a wet or a dry condition, by means of a solvent, after which it is treated as above.

Instead of producing lanolin from wool-washing water it may be obtained from commercial wool fat by stirring this wool fat together with water containing sodium carbonate, caustic soda, or a mixture of these to form a thin milky solution, which is treated in the manner above described.

The practical difficulties in the way of purifying commercial wool grease so as to make a product which shall conform to the requirements for a medicinal article are very great. Solvents, bleaching agents and other material aids are necessary and the mechanical difficulties are also of importance. Many firms attempted the task during the war when the price was high but only a few were successful. (See *Ph. Era,* 1917, p. 279.)

Description and Physical Properties.—"A brownish-yellow, tenacious, unctuous mass, having not more than a slight odor. Wool Fat is insoluble in water, but mixes without separation with about twice its weight of water. It is sparingly soluble in cold alcohol, more soluble in hot alcohol, and freely soluble in ether and in chloroform.

"Wool Fat melts between 38° and 42° C. Dried to constant weight on a water bath with frequent stirring, Wool Fat loses not more than 0.5 per cent. of its weight (*water*). Ash: not more than 0.1 per cent. Dissolve 2 Gm. of Wool Fat in 10 cc. of ether, and add 2 drops of phenolphthalein T.S.: the liquid is not colored red (*free alkalies*), but on the addition of 0.2 cc. of tenth-normal sodium hydroxide a deep red color is produced (*free fatty acids*). Boil 1 Gm. of Wool Fat with 20 cc. of alcohol under a reflux condenser, cool, filter, and add to the filtrate 5 drops of an alcoholic solution of silver nitrate (1 in 50): the turbidity, if any, is not greater than that produced by the same quantity of the silver nitrate solution in a mixture of the same volume of alcohol and 0.5 cc. of fiftietn-normal hydrochloric acid (*chloride*). Warm 10 Gm. of Wool Fat with 50 cc. of distilled water on a water bath, constantly stirring the mixture until the Wool Fat is melted: the fat separates completely on cooling, leaving the aqueous layer nearly clear and neutral to litmus paper. A 10 cc. portion of the filtered aqueous layer leaves no sweet residue on evaporation (*glycerin*). Another 10 cc. portion of the filtrate emits no *ammonia* vapors when boiled with 1 cc. of sodium hydroxide T.S., and a further 10 cc. portion does not completely decolorize 0.05 cc. of tenth-normal potassium permanganate within ten minutes (*soluble oxidizable impurities*). About 0.5 Gm. of Wool Fat dissolves completely in 40 cc. of boiling dehydrated alcohol (*petrolatum*). Iodine value: not less than 18 and not more than 28, using 0.8 to 0.85 Gm. of Wool Fat.

"Preserve in a cool place in well-closed containers which are impervious to fat." *U. S.*

"A yellowish, tenacious, unctuous substance. Almost inodorous. Melting point about 40° C. When a solution of 0.1 gramme in a mixture of 5 millilitres of *chloroform* and 0.5 millilitre of *acetic anhydride* is gently poured upon the surface of 5 millilitres of *sulphuric acid* in a test-tube, a purplish-brown ring, the upper layer of which gradually becomes green, is developed at the surface of contact (presence of cholesterol). A solution of 0.2 gramme in 10 millilitres of *ether* remains colorless on the addition of 2 drops of *solution of phenolphthalein* (absence of free alkali), but becomes deep red on the addition of 1 drop of *N/1 solution of sodium hydroxide* (limit of free acid). Heated with *solution of sodium hydroxide* no ammoniacal odor is evolved (absence of organic nitrogenous matter). Ash not more than 0.3 per cent." *Br.*

For account of uses see under *Adeps Lanæ Hydrosus.*

Off. Prep.—Adeps Lanæ Hydrosus, *U. S., Br.*

ADEPS LANÆ HYDROSUS. U. S., Br.

HYDROUS WOOL FAT Adeps Lan. Hyd. [Lanolin]

"Hydrous Wool Fat consists of wool fat incorporated with not less than 25 per cent. and not more than 30 per cent of water." *U. S.*

Lanoline; Lanolin, Adeps lanæ cum aqua, *P. G.*; Wasserhaltiges Wollfett, *G.*; Lanolina, *It.*, *Sp.*

"Wool Fat, 70 grammes; Distilled Water, 30 millilitres. Mix." *Br.*

Description and Physical Properties.—"A yellowish-white, or nearly white, ointment-like mass, having not more than a slight odor. Hydrous Wool Fat is insoluble in water.

"With ether and with chloroform Hydrous Wool Fat yields turbid solutions which are neutral to moistened litmus paper. Hydrous Wool Fat heated on a water bath separates into an upper oily and a lower aqueous layer. When the heating is continued with frequent stirring until it ceases to lose weight, not less than 70 per cent. and not more than 75 per cent. of residue remains, which, when melted, is transparent and when cold, is a yellowish, tenacious, unctuous mass completely soluble in ether or chloroform and only sparingly soluble in alcohol. Hydrous Wool Fat thus deprived of water meets the requirements of the test for *petrolatum* under *Adeps Lanæ.* Hydrous Wool Fat complies with the tests for *free alkalies, free fatty acids, chloride, glycerin,* and *ammonia* described under *Adeps Lanæ,* allowance being made for the proportion of water present.

"Preserve in a cool place, in well-closed containers which are impervious to fat." *U. S.*

"10 grammes heated on a water-bath, with stirring, until the weight is constant, yield not less than 7 grammes of a residue which responds to the tests described under 'Adeps Lanæ.'" *Br.*

Uses.—As an ointment base wool fat has the following advantages over lard: it will absorb a larger quantity of water; it is less likely to become rancid; because of its stickiness it adheres more pertinaciously to the skin, and because of the difficulty in saponifying it it is less liable to be washed off. Because of its consistence it usually requires some thinning with cottonseed or other oil. It has been claimed for wool fat that it passes through the skin more readily than other ointment bases and is therefore especially suitable when it is desired to have medicaments absorbed. The fact, however, that this is a sebaceous secretion intended by nature to soften fibers of the wool and not for absorption, a priori would seem to render such a view improbable, and in the experiments of Sutton and of Gardiner it was found that wool-fat penetrated the skin much less readily than did lard. (See under *Unguenta.*)

ADONIS. N. F.

ADONIS Adon.

"Adonis is the overground portion of *Adonis vernalis* Linné (Fam. *Ranunculaceæ*). Adonis contains not more than 5 per cent. of foreign organic matter." *N. F.*

Pheasant's Eye, Vernal Pheasant's Eye, False Hellebore Spring Adonis. Sommerteufelsauge, *G.*

The *Adonis vernalis* is an erect perennial herb a little less than one foot high, with light green, pinnatifid leaves and conspicuous yellow solitary flowers and achene fruits. It is a native of northern Europe and Asia. Its rhizome sometimes occurs in commercial black Hellebore as an adulterant.

The commercial supply of Adonis comes to the United States from Hamburg, Germany.

Adonis aestivalis L. or *summer adonis* has recently been offered as a substitute for the genuine article. It may be distinguished from the latter by its crimson flowers and by its stem which unlike that of *A. vernalis* is branched at the top.

Description and Physical Properties.—"*Unground Adonis.*—Glabrous, with the exception of the younger portions which may be slightly grayish puberulent; stems from 15 to 50 cm. in length, longitudinally grooved, soft and weak, shining, simple or branched, the branches mostly from near the base and similar to the main stem, naked below, except for some scale-like leaf vestiges, densely leafy above; leaves from 2 to 4 cm. in length and two-thirds or more as broad, pinnately divided into several segments, the larger again divided, the ultimate segments being narrowly linear and acute; flowers terminal, yellow but usually drying to a cream color, from 3 to 6 cm. in breadth; sepals five, green or grayish puberulent, more than half the length of the petals, oblong, obtuse, finely nerved; petals from five to twenty, oblong, obtuse, finely nerved; stamens indefinite; pistils numerous, in fruit forming an ovoid, obtuse, dense head of ovoid achenes, which are tipped with the very small persistent styles. Odor faint; taste bitterish, slightly acrid.

"*Powdered Adonis.*—Grayish green; abundant pith parenchyma, the cells up to 0.050 mm. in width and 0.250 mm. in length, and with few simple pores; groups of long narrow fibers, mostly with lignified walls, the latter 0.005 to 0.007 mm. in thickness and having a few rounded or oblique simple pores; tracheæ spiral or with bordered pores and up to 0.017 mm. in width; epidermal cells from the stem and petiole elongated in surface view or from the blade composed of finely striated cells with wavy, vertical walls; elliptical stomata, the latter up to 0.064 mm. in length; brownish colored fragments from the scales at the base of the stem, composed of elongated cells with rounded ends and yellowish-brown walls; starch grains and calcium oxalate crystals few or absent." *N. F.*

Constituents.—Cervelo, in 1882, obtained from the plant a glucoside, to which he gave the name of *adonidin*. For improved method of preparation, see *P. J.*, vol. xvi, 145, and *A. J. P.*, 1887, 609. This glucoside occurs in the form of a somewhat hygroscopic, canary-yellow powder of an intensely bitter taste; soluble in water, alcohol, and in amyl alcohol; insoluble in anhydrous ether, chloroform, oil of turpentine, or petroleum benzin. Podwyssotzki found commercial samples of adonidin to be mixtures containing the active substance *picroadonidin*, which he describes as an amorphous glucoside having an excessively bitter taste easily soluble in water and alcohol and entirely soluble in ether. (*P. J.*, 1888, xix, 346.) According to Fuckelman, confirmed by Mercier (*Nouv. Rem.*, 1914), commercial adonidin is a mixture of a neutral body with a hemolytic acid, *adonic acid.*

Merck has described another crystalline principle, which fuses at 102° C., is very soluble in water and warm alcohol, and crystallizes in clear needle-like prisms. It has a neutral reaction, does not reduce Fehling's solution, and is not colored brown by alkalies. Its analysis formula is $C_5H_{12}O_5$, and Merck considers it to be a hitherto undescribed pentatomic alcohol, and calls it *adonite.* Whether it be identical with the *adonidulcite* announced in a preliminary communication by Podwyssotzki shortly before his death, Merck is not able to state, as no details of fusing point, formula, or chemical reaction were given by the former. (*M. Bull.*, Jan., 1893.) E. Fischer (*B. Chem. G.*, 1893, 633) has confirmed the findings of Merck.

Other species of adonis seem to possess similar properties to the official. Cervello (*A. E. P. P.*, xv) states that the glucoside adonidin exists in the *A. cupaniana.* Tahara (*B. Chem. G.*, 1891, xxiv) found an allied glucoside *adonin* in the *A. autumnalis* and Inoko (*A. E. P. P.*, xxviii) a glucoside also related to adonidin in the *A. amurensis* of Japan. Borgiotti (*D. M. Ztg.*, 1888) from clinical experience has found the *A. aestivalis* physiologically active.

Uses.—Adonidin belongs physiologically to the digitalis group. Although in Hare's experiments (*T. G.*, 1886) the frog's heart was arrested in diastole, Cervello (*A. E. P. P.*, xv) Schmidt (*A. J. P.*, 1920, xcii, 702) found that the arrest is systolic. The pulse is slowed by stimulation of the inhibitory apparatus. In the experiments of Henrijean (*B. A. R. B.*, 1909, xxiii, p. 363) in the early stages of the action, electrical stimulation of the pneumogastric nerve produced an unwonted degree of retardation of the pulse rate, which would indicate an increased excitability of the peripheral ends of the nerves. All investigators are in accord that the slowing of the pulse is to a large extent abolished by section of the vagi, so that the inhibitory influence must be largely also of central origin. There occurs also a pronounced rise of the blood pressure, which, according to Hare, is due partly to a stimulant action upon the heart, and partly to an effect upon the vasomotor mechanism. In the more exact experiments of Henrijean, vaso-constriction appeared only late in adonidin poisoning. After large toxic doses, the heart becomes irregular, and the blood pressure falls. According to Kakowski (*A. I. P. T.*, xv, p. 21), adonidin differs from most of the other digitalis group in that it dilates the coronary arteries, while most of these drugs produce constriction.

Adonis vernalis was introduced as a cardiac tonic by Bubnow in 1879. Clinical experience confirms the conclusion of the pharmacologist, that it resembles digitalis in its action, and is a useful agent in the treatment of chronic *heart disease.* The advantages which have been claimed for it are, that it is more prompt in its action, and that it manifests less cumulative tendency than digitalis, but it appears to be less certain in its effect. Bechterew asserts that it is a useful remedy in *epilepsy* when used in conjunction with the bromides. Under the name of *panadonine,* a preparation of the Japanese *A. Davurica* has been introduced into medicine, not only for its cardiac effect but also as an analgesic in *neuralgia.*

The *dose* of *Adonis vernalis* is from one to five grains (0.06–0.3 Gm.). The glucoside adonidin may be given in doses of one-twelfth to one-fourth of a grain (0.005–0.015 Gm.).

Off. Prep.—Fluidextractum Adonis, *N. F.*

ÆTHER. U. S. (Br)

ETHER

"Ether contains from 96 per cent. to 98 per cent. of $(C_2H_5)_2O$, the remainder consisting of alcohol and water. *Caution.*—Ether to be used for anesthesia must be preserved only in small well-closed containers, and is not to be used for this purpose, if the original container has been opened longer than twenty-four hours." *U. S.* "Ether, also known as ethylic ether, $C_4H_{10}O$, may be obtained by distilling a mixture of ethylic alcohol or industrial methylated spirit and sulphuric acid, and rectifying the distillate. It should be preserved in a cool dark place." *Br.*

Æther Purificatus, *Br.*, Purified Ether; Stronger Ether; Anesthesia Ether, Æther sulphuricus, Æther Oethylicus; Sulphuric Ether, Naphtha Vitrioli, Hydrate of Ethylen, Oxide of Ethyl; Ethoxyethane; Ether officinal, Ether pur, *Fr. Cod.;* Ether hydrique, ou vinique, ou sulphurique, *Fr.;* Aether, *P. G.;* Reiner Aether, Schwefeläther, *G.;* Etere, *It.;* Eter, Eter sulfurico, *Sp.*

Attention should be directed to the unfortunate difference in nomenclature between the British and American Pharmacopœias. The former authority recognizes two grades of ether, the inferior of which is denominated simply ether and the superior grade, corresponding to the ether of the U. S. P., is known as "purified ether."

Ether is the oxide of ethyl (C_2H_5). It is commonly formed from alcohol (ethyl hydroxide) by the action of sulphuric acid, according to the following reactions:

$$C_2H_5OH + SO_2OH.OH = SO_2OH.OC_2H_5 + HOH$$

that is, alcohol reacting with sulphuric acid yields ethyl-sulphuric acid (*sulphovinic acid*) and water. In the presence of an excess of alcohol and at the proper temperature the ethyl-sulphuric acid then reacts with another molecule of alcohol, as follows:

$$C_2H_5OH + SO_2OH.C_2OH_5 = C_2H_5OC_2H_5 + SO_2OH.OH$$

whereby ethyl oxide (ether) is formed, and sulphuric acid is regenerated. These reactions take place best at a temperature of about 140° C., and if the mixture in the still is kept at this temperature a steady stream of alcohol can be converted into ether, whence the process has been called "the continuous etherification process."

Preparation.—A process for preparing ether upon the small scale was given in the U. S. P., 1870, and a former British Pharmacopœia, (see *U. S. D.*, 18th ed., p. 118), but it was properly abandoned by both Pharmacopœias, as the production of this inflammable and very volatile liquid should be undertaken only in buildings properly safeguarded, and it is now made of excellent quality on a large scale with special apparatus. Ether was made officially by the action of sulphuric acid upon alcohol, in a glass flask, at a temperature ranging between 130° C. and 137.7° C., the distillate being afterwards rectified to remove impurities.

In the apparatus employed by E. R. Squibb the ether is made in one operation; the vapors of ether and unchanged alcohol are first washed by a solution of caustic potash maintained at a temperature above the boiling point of alcohol, the alcoholic vapor being condensed in a worm condenser kept at a suitable temperature and runs back into the still, while the ether vapor, retaining about 4 per cent. of alcohol, is condensed in a well-cooled apparatus. Three hundred and sixty pounds of concentrated sulphuric acid are sufficient to etherify 120 barrels of clean spirit; the acid has then to be changed, chiefly because the impurities of the spirit render the mixture dark and tarry and liable to froth in the still. One of the wartime ether plants run on the continuous principle as above described showed the following figures of materials and labor used for each ton (2240 lbs.) of ether produced: 3200 lbs. alcohol, 3 lbs. sodium hydroxide, 3 lbs. sulphuric acid, 9000 gallons water, 6000 lbs steam, one foreman and four laborers. The capacity of this plant was 25 tons per day. Kraft proposes to manufacture ether by heating alcohol in contact with the alkyl esters of sulphonic acid. He states that benzene-sulphonic acid under favorable conditions is capable of converting several thousand times its weight of alcohol into ether. The advantage claimed for this method is greater purity of the resulting ether. (*Chem. Ztg.*, 1893, 1876.) Methionic acid, $CH_2(HSO_3)_2$, is used in manufacturing ether under the patents of Schroeter and Sondag. In Senderens' process the alcohol vapor is transformed into ether by passing it over alumina (Al_2O_3) heated to exactly 260° C. Ekenberg purifies ether by mixing it with 5 or 10 per cent. of liquid paraffin, which has a boiling point of about 300° C. and distilling at a temperature of from 40° to 50° C. The liquid paraffin holds the impurities and permits the pure ether to distill over. (*Chem. Ztg.*, 1894, 1240.)

It is necessary to draw a sharp distinction between the official ethers of the two Pharmacopœias. The strength of the official ether of both Pharmacopœias is practically the same, that of the American having specific gravity of 0.713 to 0.716 at 25° C., that of the British 0.720 at 15.5° C. The British "Aether" differs from the substance official in the U. S. P. under the same name in that there is no official test for limit of aldehyde or methyl compounds. The substance intended for anesthetic purposes and corresponding to the ether of the U. S. P. is known in the Br. P. as "Aether purificatus."

Description and Physical Properties.—"A transparent, colorless, mobile liquid, having a characteristic odor, and a burning, sweetish taste. It is highly volatile and inflammable. Its vapor when mixed with air and ignited may explode violently. It is slowly oxidized by the action of air, moisture, and daylight with the formation of peroxides. Ether is soluble in about 12 times its volume of water at 25° C., with slight contraction of volume. It is miscible with alcohol, benzene, chloroform, petroleum benzin, and fixed or volatile oils.

"Specific gravity: 0.713 to 0.716 at 25° C. Boiling point: about 35° C.

"The color of light blue litmus paper moistened with water is not changed to red when the paper is immersed in Ether for ten minutes. Allow 50 cc. of Ether to evaporate spontaneously from a shallow dish, and dry at 100° C. for one hour: the residue does not exceed 0.001 Gm. Place 10 cc. of 80 per cent. alcohol in a 50 cc. glass-stoppered flask, add 0.5 cc. of phenolphthalein T.S., and just sufficient fiftieth-normal sodium hydroxide to produce a pink color which persists after shaking for one-half minute. Then add 25 cc. of Ether, stopper the flask, mix gently, and add again fiftieth-normal sodium hydroxide until the pink color persists after shaking for one-half minute: not more than 0.4 cc. additional fiftieth-normal sodium hydroxide is required to neutralize the Ether (*acid*). Pour 10 cc. of Ether, in portions, upon clean, odorless blotting paper, and allow it to evaporate spontaneously: no foreign odor is perceptible when the last traces of Ether evaporate from the paper. Shake 10 cc. of Ether occasionally during two hours with 1 cc. of potassium hydroxide T.S. in a glass-stoppered container, protected from light: no color is developed in either liquid (*aldehyde*). Shake 10 cc. of Ether occasionally during one hour with 1 cc. of a freshly made solution of cadmium and potassium iodide (1 in 10), in a glass-stoppered cylinder, previously rinsed with the Ether under examination and protected from light: no color develops in either liquid (*peroxide*).

"Preserve in partially filled, well-closed, light-proof containers, in a cool place, remote from fire." *U. S.*

Under the title "Ether" the British Pharmacopœia gives the following description:

"A colorless, very volatile and inflammable liquid. Odor and taste strong and characteristic. Slightly soluble in *water;* miscible in all proportions with *alcohol* (90 per cent.), *chloroform,* and fixed and volatile oils. Specific gravity 0.720. Boiling point from 34° to 36° C. Its vapor mixed with air is explosive in contact with flame. 5 millilitres, on spontaneous evaporation in a glass dish, leave a film of moisture which does not redden or bleach *blue litmus paper* (absence of free acid, sulphurous acid)." *Br.*

The British Pharmacopœia gives the following tests for purified ether: "Purified Ether possesses the characters and responds to the tests described under 'Æther,'" with the following requirements in addition: "Kept in contact with *potassium hydroxide* freshly broken into small fragments, in a well-stoppered white glass bottle in the dark, no yellow coloration is developed within one hour. Mixed with one-tenth of its volume of freshly prepared *solution of potassium iodide,* it does not develop a yellow color within three hours when kept in a completely filled white glass-stoppered bottle in the dark and frequently shaken. Yields no reaction with the following test for methyl compounds: Well shake 2 volumes of the Purified Ether in a separating funnel with 1 volume of *alcohol* (20 per cent.) and 1 volume of *water,* allow the mixture to separate, and draw off the lower layer. Mix 5 millilitres of this lower layer in a wide test-tube with 2.5 millilitres of an aqueous solution (1 in 50) of *potassium permanganate* and 0.2 millilitre of *sulphuric acid.* At the end of three minutes add to the contents of the tube 0.5 millilitre of an aqueous solution (9.6 in 100) of *oxalic acid,* followed by 1 millilitre of *sulphuric acid,* and then by 5 millilitres of *decolorised solution of fuchsin;* mix thoroughly and set aside for twenty minutes. No violet color is produced (absence of methyl compounds)." *Br.*

Commercial ether, which is sometimes used as a solvent, varies in sp. gr. from 0.733 to 0.765. The impurities found in it are excess of alcohol, water, sulphurous and other acids, heavy oil of wine, and various fixed substances.

According to R. Boettger, water may be detected in ether by agitating the suspected liquid with carbon disulphide; if water be present the mixture becomes milky and turbid, otherwise it remains clear. The most delicate test, however, according to George B. Frankforter and E. A. Daniels (*J. Am. C. S.,* 1915, p. 2560) is anhydrous aluminum chloride which when dropped into ether produces a delicate white cloud or a milky layer according to the amount of water present. For the detection of alcohol Stefanelli (*B. Chem. G.,* viii, 439) proposed to shake ether with a small fragment of aniline-violet, which does not impart color to ether free from alcohol. One per cent. of alcohol may be thus detected. A delicate test for the presence of alcohol in ether is that of Lieben, founded on the formation of iodoform by alcohol but not by ether. The mere keeping of ether in the presence of moisture is said to generate sufficient alcohol to produce the reaction. (Allen, *Com. Org. Anal.*) Ether is usually made anhydrous by allowing it to remain in contact with dry calcium chloride or by distilling it with a small quantity of metallic sodium in a flask or retort.

The extreme volatility of ether causes it to evaporate speedily in the open air, with the absorption of considerable heat. Its inflammability is very great, and the greatest care should be used not to bring it in the vicinity of a naked flame; ether vapors may ignite from a flame several feet away from the ether. When too long kept it undergoes decomposition, and is converted in part into acetic acid and organic peroxides. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the vegetable alkaloids. It does not dissolve potassium or sodium hydroxide, in which respect it differs from alcohol.

On filtering an ethereal liquid with free access of air, a frost-like congelation is observed on the upper part of the filter, its appearance and quantity depending upon the temperature and the hygrometric state of the atmosphere. Tanret has collected some of this *ether hydroxide,* and found that after it had been completely freed from ether by strongly blowing upon it, it had the temperature –3.5° C., and on fusion yielded 17 to 18 parts of water for 37 of ether; the formula $(C_2H_5)_2O,2H_2O$ requires 18 parts.

Uses.—As early as 1805, inhalations of ether were recommended by Warren, of Boston, to relieve pulmonary distress in advanced *phthisis,* and in 1812 ether intoxication by inhalation is said to have been frequently practiced. It seems to have been first used as anesthetic by Dr. C. W. Long, of Georgia, but it was not until October, 1846, that Warren, at the instance of W. T. G. Morton, of Boston, used ether as a surgical anesthetic at the Massachusetts General Hospital and made its value public knowledge. A few days subsequently, C. T. Jackson, of Boston, claimed to have first made known to Morton the use of ether for the prevention of pain in dental operations.

Locally, ether is a violent irritant. It is absorbed through the lungs with very great rapidity, and less quickly, but with equal certainty, through the mucous membrane of the gastro-intestinal tract, and is eliminated through the lungs.

Ether is predominantly a paralyzant to the central nervous system affecting first the cerebral centers, then the spinal cord, and at last the vital centers in the medulla. The condition of surgical anesthesia is really one of advanced poisoning which is made reasonably safe only by the fact that the vital centers are involved so late and that the volatility of the ether allows it to be rapidly eliminated through the lungs. Although eventually both sensory and motor apparatus are paralyzed, the effect occurs much earlier in the sensory side of the organism than in the motor. The action upon the circulation is of relatively minor importance, although it is probable that this drug affects the circulatory apparatus much as does alcohol; that is, after small doses there is a slight stimulation of the heart with dilatation of the peripheral blood vessels and generally a slight increase in the blood pressure. After large doses both the heart and vascular system are depressed and the arterial tension greatly reduced. When pushed to a fatal termination ether poisoning nearly always causes death from respiratory failure.

As a practical anesthetic, ether is inferior to chloroform in being distinctly slower in action, more disagreeable to the patient by producing greater excitement and in being more apt to cause prolonged nausea and vomiting after its use. Statistics show, however, that the proportion of deaths due to chloroformization is four to five times greater than after etherization; and only in rare circumstances is the surgeon justified for the sake of convenience in selecting the more dangerous anesthetic.

It being impossible in the space which can be allotted to the subject in the present work to discuss to any advantage the subject of surgical etherization, either in its general, theoretical, or practical aspects, the reader is referred to H. C. Wood, Jr.'s *Textbook of Pharmacology.*

Given by the mouth, ether may be used in *nausea* dependent upon gastric depression, in excessive *flatulence,* especially when attended by colic, and in *gastrodynia.* It has also been recommended by Andrain (*Press. Med.,* Aug. 16, 1919) by intramuscular injection for the relief of *whooping-cough.* As a constituent of Hoffmann's anodyne it is much used as a stimulant antispasmodic. For administration by the mouth it is best given floating on ice-cold water, though it is sometimes administered in a syrup which may be made by shaking together in a bottle 440 parts of sugar, 490 parts of distilled water, 50 parts of alcohol (sp. gr. 0.833), 20 parts of ether. If the parts taken are grains the formula would give one dose.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

Off. Prep.—Spiritus Ætheris, *N. F.;* Spiritus Ætheris Compositus, *N. F.*

ÆTHER ACETICUS. N. F., Br.

ACETIC ETHER Æth. Acet. [Ethyl Acetate]

"Acetic Ether is a liquid obtained by distilling a mixture of ethylic alcohol, acetic acid, and sulphuric acid, and purifying the product. It contains not less than 90 per cent. of ethyl acetate, $C_2H_5C_2H_3O_2$." *Br.* "A liquid containing not less than 96 per cent., by volume, of $C_4H_8O_2$ or $CH_3CO.OC_2H_5$ (88.08), the remainder consisting of alcohol and a little water." *N. F.*

Naptha Aceti; Vinegar Naptha; Acetas Ethylicus; Æthylium Aceticum, *Fr. Cod.;* Acétate d'Ethyl, Ether acétique, Naphte acétique, *Fr.;* Aether aceticus, *P. G.;* Essigäther, Essignaphtha, *G.;* Etere acetico, *It.;* Eter acetico, *Sp.*

Acetic ether is not official in the U. S. X. The Br. Pharm., 1914, and N. F. V retain it.

Preparation.—A process for preparing this ether will be found in a former British Pharmacopœia (1885). It is a modification of the process recommended by W. I. Clark (*P. J.*, 1883, p. 777), and is as follows: "Take of Rectified Spirit, 32¼ fluidounces [Imp. meas.]; Sulphuric Acid, 31½ fluidounces [Imp. meas.]; Acetate of Sodium, 40 ounces [av.]; Carbonate of Potassium, freshly dried, 6 ounces [av.]. To the spirit slowly add the acid, keeping the fluid cool, and, the product being cold, add the acetate, mixing thoroughly. Distil forty-five fluidounces [Imp. meas.]. Digest the distillate with the carbonate of potassium for three days in a stoppered bottle. Separate the ethereal fluid, and again distil until all but about four fluidounces have passed over. Preserve the resulting acetic ether in a well-closed bottle and in a cool place." *Br.*, 1885. In adition to this method, acetic ether may be made by several processes, the chief of which are the following: 1. Mix 100 parts of alcohol (sp. gr. 0.83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a well-cooled receiver. 2. Distil to dryness a mixture of three parts of sodium acetate, three of alcohol, and two of sulphuric acid, mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil two parts of efflorescent lead acetate with one part of alcohol and a little more than one part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. J. A. Pabst has devised a process for acetic ether in imitation of that for the preparation of common ether. Fifty cc. of sulphuric acid and the same quantity of alcohol are heated together in a retort to 140° C., and then a mixture of one liter of 96 per cent. alcohol and one liter of acetic acid (93 per cent.) is allowed to flow in slowly. At first some ethyl ether goes over, and then a liquid which contains, with considerable uniformity, 85 per cent. ethyl acetate. The reaction takes place between 130° C. and 135° C.; at 145° C. some sulphurous acid is produced. The yield is about 1350 grammes, or 78 per cent., which is 90 per cent. of the theoretical amount. The *methyl acetate* can be prepared exactly as the ethyl compound, but in the attempt to prepare the amyl acetate in an analogous manner, side reactions were found to interfere. In order to study the proportional power of combination possessed by the two alcohols, Pabst allowed a mixture of 100 cc. methyl alcohol and 100 cc. acetic acid to flow into a mixture of 50 cc. sulphuric acid and 50 cc. ethyl alcohol. The first distillates contained essentially methyl acetate and the latter pure ethyl acetate. In the flash were found remaining nearly equal amounts of sulphuric and ethyl-sulphuric acids, and in addition alcohol, acetic acid, and some residual ethyl acetate. (*Bull. Soc. Chim.*, xxxiii, p. 350; *A. J. P.*, 1880.)

Ethyl acetate often forms in galenical preparations which contain both acetic acid and alcohol in the menstruum and which have been allowed to stand for some time. This sometimes is a disadvantage, for it causes differences between a freshly made and an old preparation which require an explanation when a change is made from one to the other, as in refilling a prescription.

Description and Physical Properties.—"Acetic Ether is a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste. Specific gravity: 0.890 to 0.896 at 25° C. One cc. of Acetic Ether is soluble in about 10 cc. of water at 25° C., miscible with alcohol, ether, or fixed or volatile oils.

"It does not immediately redden blue litmus paper. Boiling point: from 72° to 77° C. Acetic Ether is readily volatilized, even at a low temperature. It is inflammable, burning with a yellowish flame and an acetous odor.

"No weighable residue remains on evaporating 10 cc. of acetic ether. Allow 10 cc. of Acetic Ether to evaporate spontaneously from clean, odorless blotting paper; the final odor does not resemble that of pineapple (*butylic* or *amylic derivatives*). Pour carefully 2 cc. of Acetic Ether on 10 cc. of sulphuric acid; no dark ring is developed at the point of contact of the two layers within fifteen minutes (*readily carbonizable organic impurities*). Mix 20 cc. of Acetic Ether with a solution of 20 Gm. of sodium hydroxide in 50 cc. of distilled water, allow the mixture to stand, agitating occasionally, or heat it gently under a reflux condenser, until a homogeneous liquid results, and then distil about 25 cc. This distillate complies with the Test for absence of methanol under Alcohol in the U. S. Pharmacopœia X. Shake 25 cc. of Acetic Ether in a graduated cylinder with 25 cc. of distilled water just previously saturated with Acetic Ether; the ethereal layer when separated measures not less than 24 cc. (undue proportion of *alcohol* or *water*).

"Preserve it in well-stoppered bottles, in a cool place, remote from fire and protected from light." *N. F.*

The British Pharmacopœia describes it as "a colorless liquid with a fragrant odor. Soluble in all proportions in *alcohol* (90 per cent.), in *ether* and in *chloroform*, and in not less than 11 parts of *water*. Specific gravity 0.900 to 0.907 at 15.5° C. Moistened *blue litmus paper* introduced into it is not immediately reddened. A little allowed to evaporate from filter paper leaves no extraneous odor. When carefully poured over *sulphuric acid* no dark ring is formed within fifteen minutes at the surface of contact. Contains not less than 90 per cent. of ethyl acetate as determined by the following process: Introduce about 5 grammes into a tared stoppered flask, weigh, and make up to 100 millilitres with *water*. Transfer 10 millilitres of this solution to a titration flask and neutralise with *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Then add 20 millilitres of the alkaline solution, set aside for five minutes, rotating occasionally, dilute with *water* and titrate back with *N/1 solution of sulphuric acid.* Deduct from 20 the number of millilitres of the acid solution required. Each millilitre of the difference corresponds to 0.088 gramme of ethyl acetate." *Br.*

With reference to the solubility of acetic ether in saturated calcium chloride solution, it is to be remarked that pure acetic ether is not dissolved, except when it is mixed with 90 per cent. alcohol. One volume acetic ether, one volume alcohol, and two volumes calcium chloride solution give a homogeneous liquid.

Uses.—Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. Its action upon the system is probably very similar to that of ether; but as it is less volatile it is less rapidly absorbed and eliminated, and consequently is much less prompt and fugacious in its influence than is ether. It is locally irritating. H. C. Wood found it to be capable of being used as an anesthetic, but to be too slow in its action for practical purposes. It is sometimes employed externally, by friction, as a resolvent, and for *rheumatic pains.*

Its most important use is as a flavoring agent.

ÆTHYLIS AMINOBENZOAS. U. S.

ETHYL AMINOBENZOATE

Æthyl. Aminobenz.—[Benzocaine]

$C_6H_4NH_2COO(C_2H_5)1:4$

This base, which was introduced under the proprietary name of *anesthesin,* is the ethyl ester of paraminobenzoic acid. It is prepared by the following method: Para-nitrobenzoic acid is heated with sodium sulphide and solution of sodium hydroxide. This solution, after cooling and acidulating, is boiled to expel SO_2 and sodium acetate is then added which causes the crystallization of paramidobenzoic acid, which is then esterified by heating with ethyl alcohol and sulphuric acid.

Description and Physical Properties.—"Small white or colorless crystals, or a white crystalline powder. It is odorless, and is stable in the air. One Gm. of Ethyl Aminobenzoate is soluble in about 2500 cc. of water, 5 cc. of alcohol, 2 cc. of chloroform, 4 cc. of ether, and in from 30 to 50 cc. of expressed oil of almond or olive oil, at 25° C. It is soluble in dilute acids.

"Ethyl Aminobenzoate melts between 88° and 90° C. When boiled with alkali hydroxides, alcohol is liberated. Dissolve about 0.02 Gm. of Ethyl Aminobenzoate in 10 cc. of distilled water with the aid of a few drops of diluted hydrochloric acid, and add to the solution 5 drops of a 10 per cent. sodium nitrite solution, followed by 2 cc. of a solution of 0.1 Gm. of beta-naphthol in 5 cc. of sodium hydroxide T.S.: an orange-red precipitate is produced. Its aqueous solution (1 in 50), prepared with the aid of a slight excess of diluted hydrochloric acid, yields a precipitate with iodine T.S., and instantly reduces potassium permanganate T.S.

"Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of Ethyl Aminobenzoate in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Dissolve 1 Gm. of Ethyl Aminobenzoate in 10 cc. of neutral alcohol: a clear solution results. Dilute this solution with 10 cc. of distilled water, add 2 drops of phenolphthalein T.S. and 1 drop of tenth-normal sodium hydroxide: a red color is produced (*free acid*). The addition of a few drops of silver nitrate T.S. to a solution of 0.2 Gm. of Ethyl Aminobenzoate in 5 cc. of alcohol, previously acidulated with a few drops of diluted nitric acid, produces no immediate turbidity (*chloride*). An aqueous solution of Ethyl Aminobenzoate (1 in 20) prepared with the aid of just sufficient hydrochloric acid meets the requirements of the test for *heavy metals.* Heat a crucible to redness, and add, in small portions, an intimate mixture of 0.2 Gm. of Ethyl Aminobenzoate, about 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, then boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve: the residue, dissolved in 5 cc. of distilled water, meets the requirements of the test for *arsenic.*" *U. S.*

Benzocaine is decomposed by prolonged boiling with water, but its oily solution can be boiled without change. It is incompatible with acids and acid salts.

Uses.—Ethyl aminobenzoate is remarkable among the local anesthetics first for its comparative insolubility, and secondly for its lack of toxicity. Closson (*Journ. Michigan State Med. Soc.,* 1914, xiii, 587) found that in oily solution, injected hypodermically, it required the enormous dose of 1.2 Gm. per kilo of body weight to kill the guinea pig, which would make it about one-twentieth as poisonous as cocaine. Kennel (*B. K. W.,* December, 1902) has reported a case in which 40 grains were administered to a patient without apparent ill-effect. It also appears to be almost free of local irritating action, although the soluble salts that it forms with acids give rise to considerable irritation. According to the investigations of Closson, the anesthetic effect is almost entirely on the nerve terminals; that is, it has very little effect upon nerve trunks as compared, for example, to cocaine. Despite its sparing solubility, it is capable of passing through mucous membranes to a sufficient extent to lessen sensation. Sollmann (*J. P. Ex. T.,* 1919, xiii, 429) found that a dusting powder containing 5 per cent. of benzocaine caused almost complete loss of sensation when applied to the gums of human beings.

Benzocaine is employed for its local anesthetic action, an ingredient of dusting powders—in the proportions of from 10 to 20 per cent. for ulcerated surfaces as *burns* and *wounds.* According to Hartmann (*Ther. Geg.,* Oct., 1902) it has a distinctly antiseptic effect. In *tuberculous laryngitis* a similar powder may be insufflated or it may be used in the form of lozenges each containing from one-third to two-thirds of a grain (0.02 to 0.04 Gm.). In *gastric ulcer* it will generally give complete relief from pain and it is useful to relieve *gastralgia* even in the absence of ulcerative conditions. Reiss (*Ther. Geg.,* 1905) highly recommends it for the relief of *vomiting* when due to gastric irritation. He has found that it counteracts the emetic effects of antimony but not those of apomorphine, indicating that its antiemetic action is not central. Dentists have found it of much service to lessen the after pains of various dental operations such as extraction of the teeth.

The hydrochloride is soluble in 100 parts of water. Although Binz has shown that this salt like the base itself is of very low toxicity it is too irritant to be of great value as a local anesthetic.

Externally, ointments containing 10 per cent. of benzocaine have been used to relieve various types of itching as *pruritus vulvæ* of *diabetes,* and *eczema.* In painful *hemorrhoids,* suppositories containing 3 to 5 grains in Oil of Theobroma are often of much value. Duhot (*Ann. de la Policlin. Centrale de Bruxelles,* February, 1903) has reported excellent results in painful *cystitis* from the injection of a solution of benzocaine in oil of sweet almonds into the bladder.

Dose, three to eight grains (0.2 to 0.5 Gm.).

ÆTHYLIS CHAULMOOGRAS. U. S.

ETHYL CHAULMOOGRATE Æthyl. Chaulmoog.

“ The ethyl esters of the fatty acids of chaulmoogra oil.” *U. S.*

Chaulmestrol. Antileprol.

As pointed out elsewhere (see *Oleum Chaulmoogras*) the therapeutic action of chaulmoogra oil seems to reside in its peculiar fatty acids known as chaulmoogric and hydnocarpic acids. The compound recognized by the U. S. under the name of Ethyl Chaulmoograte is really the ethyl ester of all the fatty acids of the oil and is therefore a mixture of ethyl chaulmoograte and *ethyl hydnocarpate.*

Description and Physical Properties.—“ A clear, pale yellow liquid, having a slight, fruity odor. It is insoluble in water, but is miscible with alcohol, chloroform, and ether.

“ Specific gravity: about 0.904 at 25° C. The specific rotation $[\alpha]_D$ of Ethyl Chaulmoograte, determined at 25° C. in chloroform, containing in each 10 cc. of solution 5 cc. of the Ethyl Chaulmoograte, and using a 100 mm. tube, is not less than $+44.5°$. A solution of 1 cc. Ethyl Chaulmoograte in 10 cc. of neutralized alcohol requires not more than 0.1 cc. of tenth-normal sodium hydroxide for neutralization, using 2 drops of phenolphthalein T.S. as indicator (*free acid*). Saponification value: not less than 190 and not more than 196. Iodine value: not less than 90 and not more than 100.

“ Preserve in well-closed containers.” *U. S.*

Uses.—The therapeutic properties of ethyl chaulmoograte are precisely those of the chaulmoogra oil (which see). It has the advantage over the oil for oral administration of being less objectionable to the taste and for intramuscular injection of being somewhat less irritant locally.

Dose, either by injection or by mouth, from eight to seventy minims (0.5–5.0 cc.).

ÆTHYLIS CHLORIDUM. U. S. (Br.)

ETHYL CHLORIDE Æthyl. Chlor.

“ Monochlorethane α[C_2H_5Cl].” *U. S.* “ Ethyl Chloride, C_2H_5Cl, may be obtained by the action of hydrochloric acid on ethylic alcohol or on industrial methylated spirit; in the latter case it will contain a small but variable proportion of methyl chloride, CH_3Cl.” *Br.*

Ethyl Chloridum, *Br.;* Hydrochloric Ether; Chlorethyl, Monochlorethane; Æthyllium Chloratum, *Fr. Cod.;* Chlorure d'éthyle, Ether Hydrochlorique, *Fr.;* Æther Chloratus, *P. G.;* Aethylchlorid, Chlorwasserstoffäther, Chloräthyl, *G.*

Preparation.—Ethyl chloride was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It consists of one atom of chlorine combined with the monatomic radical or group C_2H_5, *ethyl,* and its composition is sufficiently shown by the reaction for its production:

$$C_2H_5OH + HCl = C_2H_5Cl + H_2O$$

It may be procured by several processes, but the following is recommended. Distil a mixture of equal measures of concentrated hydrochloric acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 21.1° C. and 26.6° C., and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ethyl chloride, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ester passes forward, and is condensed in the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather or in sealed containers. Before being opened, the bottle should be cooled to the freezing point.

On the large scale it is manufactured by a process essentially the same as above described in lead lined autoclaves and employing molecular proportions of hydrochloric acid and alcohol. In another process part of the hydrochloric acid is replaced by calcium chloride and an earthenware still is employed.

Like ether some of the other ethyl esters and ethers it dissolves sulphur, phosphorus, the fixed and volatile oils, and many other substances.

Description and Physical Properties.—" At low temperatures or under pressure it is a colorless, mobile, very volatile liquid. It has a characteristic, ethereal odor, and a burning taste. When Ethyl Chloride is liberated at ordinary room temperature from its sealed container, it vaporizes at once. *As its vapor is very inflammable, do not use it near fire.* It burns with a smoky, greenish flame with the production of hydrogen chloride. Ethyl Chloride is slightly soluble in water, and is freely soluble in alcohol and in ether. Specific gravity: about 0.921 at 0° C. Boiling point: between 12° and 13° C.

" Add a few drops of silver nitrate T.S. to 10 cc. of alcohol, cool to the temperature of melting ice, and add to the clear liquid about 0.5 cc. of Ethyl Chloride cooled in the same manner: no turbidity is produced at once (*chloride*). Shake 10 cc. of Ethyl Chloride with 10 cc. of distilled water, both previously cooled to the temperature of melting ice, and allow the supernatant stratum of Ethyl Chloride to evaporate spontaneously: the residual liquid is neutral to litmus paper, and on adding to it a few drops of potassium dichromate T.S., followed by 2 cc. of diluted sulphuric acid, and boiling the mixture, no odor of aldehyde is developed, and no greenish or purplish color is produced (*alcohol*). Allow 5 cc. of Ethyl Chloride to evaporate spontaneously from a shallow dish: no foreign odor is noticeable while the last portions evaporate, and only a negligible residue remains.

" Preserve in hermetically sealed containers, in a cool place, remote from fire, protected from light." *U. S.*

" Gaseous at normal temperature and pressure, but as usually supplied it is condensed into a colorless, mobile, inflammable, and very volatile liquid. Odor pleasant and ethereal, not alliaceous; if kept in vessels provided with rubber fittings, it may acquire a slight odor of rubber. Specific gravity at 0°C., 0.920 to 0.960. *Water* which has been shaken with twice its volume of liquid Ethyl Chloride is neutral to *litmus*, and gives no opalescence or precipitate with *solution of silver nitrate* (absence of sulphur dioxide and of hydrochloric acid). *Sulphuric acid* does not become colored when shaken with ten times its volume of liquid Ethyl Chloride and, after separation and dilution with an equal volume of *water*, has no unpleasant odor, or odor of ether, and does not become turbid on the addition of *solution of silver nitrate* (absence of ether, empyreumatic matter, and certain other substances). When 0.4 gramme is saponified by heating in a stoppered bottle in a water-bath with 10 millilitres of *N/1 alcoholic solution of potassium hydroxide,* the liquid requires for neutralisation not more than 38.2 millilitres of *N/10 solution of sulphuric acid,* corresponding to a proportion of not less than 99.5 per cent. by weight of esters calculated as ethyl chloride, C_2H_5Cl." *Br.*

Uses.—Ethyl chloride is used in the manufacture of synthetic organic chemicals as an ethylating agent. Ethyl chloride is so extremely volatile that when sprayed upon the skin it absorbs sufficient heat in its vaporization to cause superficial freezing in the area to which it is applied. This freezing destroys functional activity of the peripheral nerve endings and therefore the application of ethyl chloride produces local anesthesia. It is used for this purpose for a large variety of conditions where a short and superficial anesthesia is desired as, for instance, in inserting trocar for the removal of fluid, and for the application of cautery. This method of anesthesia has also been applied for opening boils and abscesses, but is not to be recommended as it more or less interferes with the nutrition of the part. Seidelin (*L. L.,* 1913, i, 1663) destroys superficial *epithelioma* by freezing them with ethyl chloride. Ethyl chloride has also been used by inhalation as a general anesthetic. Its action in this regard is extremely rapid and fugacious, comparable to that of nitrous oxide, but it is a much more dangerous anesthetic. The statements concerning the mortality after ethyl chloride anesthesia have been extremely varied. In a critical study of the statistics of fifty thousand cases H. C. Wood, Jr. (*J. A. M. A.,* 1910, lv) reaches the conclusion that the death rate is in the neighborhood of one in six thousand anesthesias. It is perhaps less dangerous than chloroform but is certainly less safe than ether. According to Guedel (*J. A. M. A.,* 1921, lxxvii, 427) there are two types of intoxications from over doses of ethyl chloride. About 90 per cent. of the cases belong to the spasmodic type in which there are contractions of the muscles of the face, neck and larynx, and sometimes other muscles of the body with consequent obstruction to respiration and cyanosis. These cases are very difficult of treatment because the muscular spasm interferes with efforts at artificial respiration. In the rarer group of cases the symptoms are those of progressive depression similar to those caused by other anesthetics. In its physiological action it closely resembles chloroform, although it is less powerfully depressant to the heart. On account of its great inflammability it should not be used near a light or flame.

A proprietary form of ethyl chloride supplied in a special form of container is known as *Kelene.*

Dose, five to ten minims (0.3–0.6 cc.) in alcoholic solution.

ÆTHYLMORPHINÆ HYDROCHLORIDUM U. S.

ETHYLMORPHINE HYDROCHLORIDE

Æthylmorph. Hydrochl.

" The hydrochloride of a synthetic alkaloid prepared from morphine by ethylation [$C_{17}H_{18}O_2N(OC_2H_5).HCl.2H_2O$]." *U. S.*

Dioninum; Dionin; Morphinum æthylatum hydrochloricum; Æthylmorphium Chlorhydricum, *P. G.*

It is the hydrochloride of the ethyl ester of morphine, and is made by acting on morphine in the presence of an alkali with ethyl iodide. The product is purified by treatment with hot alcohol and crystallization from its solution in hydrochloric acid.

Description and Physical Properties.—" A white or faintly yellow, microcrystalline powder, having no odor. One Gm. of Ethylmorphine Hydrochloride is soluble in 8 cc. of water, and in 22 cc. of alcohol, at 25° C. It is slightly soluble in ether and in chloroform.

" It melts at about 123° C. with decomposition. Add a drop of ferric chloride T.S. to a solution of about 0.01 Gm. of the salt in 10 cc. of sulphuric acid, and warm it on a water bath: upon the addition of a drop of nitric acid the color of the mixture becomes at first green, then deep violet-blue, and finally deep red. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate which is insoluble in nitric acid.

" An aqueous solution of the salt (1 in 20) is neutral to litmus paper. The ash from 0.2 Gm. is negligible. Ethylmorphine Hydrochloride loses not more than 10 per cent. of its weight when dried to constant weight at 100° C. (*water*). Heat 5 cc. of an aqueous solution of the salt (1 in 20) with 5 cc. of sodium hydroxide T.S. on a water bath: no vapors showing an alkaline reaction to litmus paper are evolved at once (*ammonium compounds*). Dissolve about 0.05 Gm. of potassium ferricyanide in 10 cc. of distilled water, add 1 cc. of diluted ferric chloride solution (1 volume of ferric chloride T.S. to 9 volumes of water), and 1 cc. of an aqueous solution of Ethylmorphine Hydrochloride (1 in 100): no green or blue color is produced at once (*morphine*). Add 1 cc. of ammonia T.S. to 5 cc. of an aqueous solution of Ethylmorphine Hydrochloride (1 in 25): a white turbidity is produced at once (*difference from codeine hydrochloride*).

" Preserve in well-closed containers, protected from light." *U. S.*

The incompatibilities of dionin and its salts are the same as those of alkaloids and their salts in general.

Uses.—Ethyl morphine hydrochloride, in its general effect, stands between morphine and codeine, but is somewhat closer to the latter. Although it is more powerful as an analgesic and hypnotic than codeine it is greatly inferior to morphine. Internally ethyl morphine is a useful drug to allay *cough* and to relieve *pain.* As a cough sedative it is inferior in power to either morphine or diacetylmorphine, but has the advantages of being less constipating and less liable to habit formation. As an analgesic, although greatly inferior to morphine, it is useful in the same class of cases. It has also been highly recommended for the quieting of nervousness following the withdrawal of opiates in those who have been accustomed to the habitual use of this drug. Lindenmayr (*B. K. W.*, 1912) reports good results from the use of ethylmorphine in acute *coryza,* stating that it not only relieves the symptoms, but has a true curative action.

Locally ethylmorphine is decidedly irritant to the more delicate mucous membranes, as conjunctiva or nose, but seems to increase the lymph flow to an extent not explicable purely on its local irritant action. It is widely employed as a local lymphagogue in various inflammations of the eye, such as *iritis, glaucoma, corneal ulcers,* and the like. It has also been employed to a lesser extent for a similar effect upon the mucous membrane of the nose, especially in *ozena.*

Dose, one-eighth to one grain (0.008–0.065 Gm.).

AGAR. U. S.

AGAR [Agar-agar]

" Agar is the dried mucilaginous substance extracted from *Gelidium corneum* (Hudson) Lamouroux and other species of *Gelidium* and closely related Algæ. (Class *Rhodophyceæ.*)

" Agar contains not more than 1 per cent. of foreign organic matter, and yields not more than 1 per cent. of acid-insoluble ash, and not more than 16 per cent. of moisture." *U. S.*

Vegetable Gelatin, Vegetable Glue, Gelosine, Japanese (Chinese, Bengal or Ceylon) Isinglass, Japanese Gelatin, Thav, Mousse de Chine, *Fr.;* Layor Caranga.

Quite a number of the algæ belonging to the *Rhodophyceæ,* growing on the coast of Southern and Eastern Asia, contain large quantities of mucilage which is extracted and sold under the name of agar-agar. The most important species are those recognized by the U. S. Pharmacopœia. The algæ are collected, spread out upon the beach until they are bleached and then dried. They are then boiled with water and the mucilaginous solution strained through a cloth with pressure. The strained mucilage is cooled, cut into strips and thoroughly dried in the sun. The algæ are usually collected during the summer and fall, bleached and dried, but the process of the manufacture of agar-agar does not take place until cold weather and usually extends from November to February.

Most of the agar used in the United States is imported from Japan, although considerable is now being manufactured at Glendale, California, from red algæ growing along the coast of lower California. (*Pract. Drug.*, Feb., 1921.)

The following varieties of agar are known:

1.—*Ceylon Agar-agar,* consisting chiefly of *Gracilaria lichenoides,* Greville, the alga used by the *Hirundo esculenta* in the formation of its edible nest.

2.—*Macassar Agar-agar,* coming from the straits between Borneo and Celebes, consisting of impure *Eucheuma spinosum,* Ag., incrusted with salt.

3.—*Japanese Agar-agar,* known as *Japanese* *isinglass,* derived from several algæ, especially *Sphærococcus compressus,* Ag., *Gloiopeltis tenax,* J. Ag., *Gelidium corneum* Lam. and *G. cartilagineum* Gaill and other species of *Gelidium.* It occurs in European commerce either in transparent pieces, two feet long and as thick as a straw, prepared in Singapore by putting the algæ named in hot water, or, more frequently, in yellowish-white masses, a foot long and upward of an inch in width. It is the latter kind of agar-agar that is suitable for the culture of bacteria, and is employed in medicine. (*P. J.,* 1885, 188.)

Morin has investigated the *gelose* of Payen, contained in the agar-agar. When a solution of gelose is cooled, even that of 1 in 500 parts of water, a colorless, transparent, and stiff jelly is obtained, which, when heated with moderately strong nitric acid, yields *mucic* and oxalic acids. It dissolves on heating with acidulated water without yielding a jelly on cooling.

Gelose leaves 3.88 per cent. of ash, and when air-dried contains 22.85 per cent. of moisture. When dissolved there also separates out a flocculent mass amounting to 1.9 per cent. Alcohol precipitates gelose, but it cannot be obtained pure in this manner, as the precipitate contains some ash. Ellery H. Harvey (*A. J. P.,* 1925, pp. 66 and 447) by electro-dialysis was able to reduce the ash of agar content from nearly 4 per cent. to 0.81 per cent. He also gives data on adsorption, viscosity, specific gravity and other factors.

Under the name of *gelosine* a mucilaginous substance, extracted from a Japanese alga, has entered commerce in the form of dry, whitish leaves. Gelosine is soluble in alcohol and water, and is said when wet to gradually contract and expel water and the medicinal substances which it may contain. It has been proposed as a pharmaceutical basis for various preparations for local use. (See *B. M. J.,* 1886, vol. ii.) Glycerin suppositories have been made with agar-agar as a vehicle, but they contain only 70 per cent. of glycerin as compared to 90 per cent. in the official suppositories made with sodium oleate.

Description and Physical Properties.—"*Unground Agar.*—Usually in bundles from 3 to 6 dm. in length, consisting of thin, translucent, membranous, agglutinated pieces 4 to 10 mm. in width; externally yellowish-white or brownish-white, tough when damp, brittle when dry, with a slight odor and a mucilaginous taste.

"*Structure.*—Granular and somewhat filamentous; a few fragments of the spicules of sponges and a few diatoms, notably the frustules of *Arachnoidiscus Ehrenbergii* Baillon which are disk-shaped and 0.1 to 0.3 mm. in diameter, may be present.

"*Powdered Agar.*—Pale buff; in chloral hydrate T.S., fragments transparent, more or less granular, striated, angular, occasionally containing frustules of diatoms. Agar is insoluble in cold water, but slowly soluble in hot water. Boil 1 part of Agar for ten minutes with 100 parts of water and replace the water lost by evaporation. It yields a stiff jelly upon cooling.

"Iodine T.S., colors some of the fragments of Agar bluish-black with some areas bright red. A solution made by boiling 0.1 Gm. of Agar in 100 cc. of water upon cooling yields no precipitate upon the addition of tannic acid T.S. (*gelatin*), and does not produce a blue color upon the addition of iodine T.S. (*starch*)." *U. S.*

To detect agar in jams, jellies, etc., in which it is often used as an adulterant, it was formerly usually considered necessary to ash the sample and examine the acid insoluble ash for presence of the characteristic diatoms. Albert Schneider (*Pac. Pharm.,* 1912, p. 35) states that the ashing is unnecessary and often destructive of the diatoms and that they may be collected by dissolving 10 Gm. of the sample in 200 cc. of distilled water and centrifuging for thirty minutes, after which the sediment may be placed on a microscopic slide and examined.

Uses.—Under the name of agar-agar a jelly-like substance has been used as a culture medium by bacteriologists for many years. Although agar contains 60 per cent. of carbohydrates, according to Saiki (*J. B. C.,* 1906), the human digestive tract is able to utilize but a very small percentage of the food value. Its therapeutic importance depends upon the ability of the dry agar to absorb and retain moisture. Being indigestible, it passes through the intestinal tract, swelling up somewhat, owing to the absorption of water from the stomach, and gives bulk to the intestinal contents. In other words, it acts mechanically in an analogous manner to the cellulose of vegetable foods, and aids in maintaining the regularity of the bowel movements. It has been widely used in the treatment of *chronic constipation.* Of itself, when there is more or less atony of the intestinal muscles, it does not originate peristaltic movements, and therefore is frequently combined with small doses of cascara, or one of the other vegetable cathartics. It is best administered cut up in small pieces, and eaten like a cereal with the addition, if desirable, of cream and sugar. A chocolate coated form of agar is also available for those who do not like the plain agar. It is also combined with mineral oil emulsions in a number of proprietary preparations, but in these very little agar is present.

Dose, ordinarily, from two to four drachms (7.7–15.5 Gm.) of the dry agar may be administered once a day.

AGARICUS. N. F.

AGARIC [White Agaric, Larch Agaric]

"Agaric is the dried fruit body of *Polyporus officinalis* Fries (Fam. *Polyporaceæ*) deprived of its outer rind. Agaric contains not more than 5 per cent. of foreign organic matter.

It yields to boiling alcohol not less than 50 per cent. of a non-volatile resinous extract." *N. F.*

Agaricus Albus; White Agaric; Larch Agaric; Touchwood; Spunk; Tinder; Boletus Laricis; Fungus Laricis; Agaricum, *Fr. Cod.;* Funpurgatif, *Fr.;* Larchenschwamm, *G.*

The term "Agaric" is more properly applied to the fungi of the genus *Agaricus,* but most medical writers and the N. F. limit it to the fungus from *Polyporus officinalis* Fries (*Boletus laricis* Jacquin; *B. purgans* Persoon), which is found upon the old trunks of the European larch and upon *Larix sibirica* Ledebour, of Asia. The same species is found on various coniferous trees in some of the western United States and British Columbia. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. Agaricus is collected chiefly in larch forests near Archangel, dried and exported to Hamburg.

When prepared polyporus (so-called agaric) is steeped in a solution of niter, and afterwards dried, it constitutes *spunk, punk,* or *tinder,* the *amadou* of the French, which occurs in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow color, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of *Polyporus,* as *P. ungulatus, P. ribis,* etc.

Description and Physical Properties.—"*Unground Agaric.*—Light, fibrous, somewhat spongy pieces of irregular shape; grayish white to pale brown externally; yellowish and resinous internally; fracture tough, fibrous; friable but difficult to powder. Odor faint; taste, sweetish, acrid and bitter.

"*Powdered Agaric.*—Numerous non-septate, narrow, mycelial threads and few prismatic or cubical crystals of calcium oxalate from 0.010 to 0.040 mm. in diameter." *N. F.*

Agaric owes its medicinal virtues to *Agaric acid,* which is also called *laricic* and *agaricinic acid.* This is a tribasic acid, $C_{19}H_{36}OH(COOH)_3 + 1\frac{1}{2}H_2O$, occurring as an odorless, tasteless, micro-crystalline powder, melting at 141.5° C. According to J. Schmieder, agaric contains a small amount of soft resin, $C_{15}H_{20}O_4$, extracted with petroleum benzin, and from 4 to 6 per cent. of a fatty body, which is made up of (1) *agaricol,* $C_{10}H_{16}O$, fusing at 223° C.; (2) *phytosterin,* $C_{26}H_{44}O$; (3) solid hydrocarbons, $C_{23}H_{46}$ and $C_{29}H_{54}$; (4) cetyl alcohol; (5) a liquid aromatic alcohol, $C_9H_{18}O$; (6) a fatty acid, $C_{14}H_{24}O_2$; and (7) ricinoleic acid. (Schmidt, *Lehrbuch der Pharm. Chem.*, ii, 3te Auf., 1528.) J. D. Riedel has produced two phenetidides of agaric acid, for which antipyretic and anhidrotic properties are claimed. (*Ph. Ztg.,* xlvii.) *Sodium, lithium* and *bismuth agaricinates* have been prepared and introduced into medicine. An agaric growing on the *Larix leptolepis,* and used in Japan as a sacred medicine under the name of *Toboshi* or *Eburiko,* has been found by Y. Inoko to contain agaric acid. (*Sei-I-Kwai,* April, 1891.)

Fungus chirurgorum. Boletus chirurgorum, Wundschwamm, G.—*Surgeon's agaric* is the product of *Polyporus fomentarius* (L.) Fries, which is found upon the oak and beech trees of Europe. It is shaped somewhat like the horse's foot, with a diameter of from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting foot-stalk. On the upper surface it is smooth, but marked with circular ridges of different colors, more or less brown or blackish; on the under surface, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown color. It is composed of short tubular fibers compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting the fungus is August or September. It has neither taste nor odor. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, nitrogenous matter also in small quantity, potassium chloride, and calcium sulphate, and in its ash is found iron, and calcium and magnesium phosphate. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting *hemorrhage,* being applied with pressure. *P. ignarius* (L.) Fries and *P. marginatus* Fries yield similar products.

Uses.—According to Hoffmeister (*A. E. P. P.*, 1889, xxv, p. 189), in a moderate dose, agaric acid has no effect upon the system, except to paralyze the nerves of the sweat glands. When given in very large doses, it produced primary excitation of the medulla, followed by paralysis, increasing at first the blood pressure and the respiratory rate, which was followed by diminishing activity in both. The large doses also acted as an irritant to the stomach and intestine, causing vomiting and purging. The depressant action shown on the sweat glands was not shared by the other glands of the body. McCartney (*J. P. Ex. T.,* 1917, x, 83) offers the remarkable theory that its antihydrotic action is due to spasm of the muscular layer of the skin.

The most important use of agaric is in the treatment of the *colliquative sweats* of wasting conditions, such as *phthisis.* Its value in these conditions has been abundantly confirmed by clinical experience. Aside from the solanaceous drugs, it is probably the most reliable remedy that we possess for this purpose. Rosenbaum has found the *fluidextract of agaric* (*Med. Klin.,* 1906) of service in various catarrhal conditions of the alimentary tract, even in *intestinal tuberculosis.*

Under the name of *agaricin* are marketed preparations containing the active *agaric acid,* with larger or smaller amount of impurities. The *dose* of the pure principle is from one-sixth to one-half of a grain (0.01–0.03 Gm.).

Dose, of agaric, five to fifteen grains (0.3–1.0 Gm.).

ALBUMINI TANNAS. U. S.

ALBUMIN TANNATE Album. Tan.
[Albutannin]

"A compound of albumin and tannic acid." *U. S.*

Various compounds of tannin with protein substances have been introduced into medicine under proprietary names. These proprietary compounds, which probably do not differ greatly in their therapeutic properties, are described in Part II under their respective names. Because of certain advantages of these tannates of albumin in the treatment of diarrhea and of the considerable variations in their physical properties the U. S. P. X has recognized an official type which offers the advantages of the proprietary articles in a standardized form.

Leach (*J. A. M. A.,* 1920, lxxv, 1129) has tested the solubility of a number of brands of tannin albuminate. He finds that while only partially soluble in 0.2 per cent. hydrochloric acid, in artificial gastric juice they are slowly digested and become almost completely soluble at the end of 3½ hours. While a somewhat larger proportion (30 to 50 per cent.) of the drug is dissolved by a 1 per cent. solution of bicarbonate of soda they are not as completely digested by pancreatin as by pepsin; from 45 to 85 per cent. of the various specimens tested became soluble after pancreatic digestion.

Tannalbin is prepared by mixing 10 parts of a 10 per cent. aqueous solution of egg albumen with 6½ parts of a 10 per cent. aqueous solution of tannic acid. The precipitate is filtered and washed until free from excess of tannin; is then dried, powdered and heated to a temperature of 126° C. for six hours.

Description and Physical Properties.—"A yellowish-white, odorless powder. It is almost insoluble in water, alcohol, chloroform, and in ether. It is decomposed by aqueous solutions of alkali hydroxides and carbonates.

"Ash: not more than 0.3 per cent. Dry about 1 Gm. of Albumin Tannate for three hours at 100° C.: the loss does not exceed 6 per cent. Shake 1 Gm. of Albumin Tannate with 50 cc. of distilled water for five minutes and filter: a 25 cc. portion of the filtrate requires for neutralization not more than 1 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*). Digest 1 Gm. of Albumin Tannate with 200 cc. of distilled water for two hours, shaking at frequent intervals. Filter through a filter, which has not been previously moistened, into a dry flask, rejecting the first 20 cc. of the filtrate. Evaporate 100 cc. of the subsequent filtrate to dryness on a water bath and dry the residue for three hours at 100° C.: the weight of the residue does not exceed 0.06 Gm. (*soluble substances*). Place 1.5 Gm. of Albumin Tannate in a 500 cc. glass-stoppered flask. Dissolve 2.5 Gm. of sodium bicarbonate in 250 cc. of distilled water, warm the solution to 40° C., and gradually add it with agitation to the Albumin Tannate. Then add a filtered aqueous solution of 0.25 Gm. of pancreatin in 5 cc. of distilled water. Place the flask in a suitable bath, maintain at 40° C. for two hours, inverting the flask every ten minutes. Allow to remain in the bath for one-half hour longer without inverting. Filter through a counterbalanced filter, wash the undissolved residue with four 10 cc. portions of cold distilled water, and dry to constant weight at 110° C.: the weight of the residue does not exceed 0.45 Gm. Place 1.5 Gm. of Albumin Tannate in a 500 cc. glass-stoppered flask. Mix 20 cc. of normal hydrochloric acid with 230 cc. of distilled water, warm the mixture to a temperature of 40° C., and add it gradually with agitation to the Albumin Tannate. Then add a filtered aqueous solution of 0.25 Gm. of pepsin in 5 cc. of distilled water. Place the flask in a suitable bath and maintain at 40° C. for two hours, inverting the flask during the digestion every ten minutes. Allow the flask to remain in the bath for another half hour without inverting. Filter through a counterbalanced filter, wash the undissolved residue with four 10 cc. portions of cold distilled water, and dry at 110° C. to constant weight: the weight of the residue is not less than 0.6 Gm.

"Preserve protected from light." *U. S.*

Uses.—Although as shown by Sollmann (*J. P. Ex. T.,* 1921, xvii, 63) most of the commercial preparations of albumin tannate are more or less soluble in water and slightly astringent, this effect is probably due to presence of uncombined tannin as an impurity. When submitted either to peptic or pancreatic digestion the compounds are gradually broken up, liberating tannic acid, which exercises its characteristic astringent effect. The digestion by pepsin is, however, so slow that under ordinary conditions it is not probable that any considerable amount of tannin will be liberated in the stomach. Therefore, the astringent effect is felt mostly in the intestinal tract. According to the experiments of Sollmann the pancreatic digestion which takes place in the intestines is also very slow, so that an astringent action will be continued throughout almost the whole of the alimentary canal. As the tannin is liberated gradually the astringency will evidently be comparatively mild in its effect.

Albutannin is used in medicine solely as an astringent in the treatment of *diarrheas.* It has the advantage over the vegetable astringents in that it is much less likely to produce gastric disturbances. While more mild in its action than the vegetable astringents it probably continues its effect throughout the whole length of the alimentary canal and is especially used in those cases of *chronic enteritis* involving the lower portions of the small bowel and even of the colon.

Dose, from fifteen to sixty grains (1–4 Gm.) three or four times a day.

ALCOHOL. U. S. (Br.)

ALCOHOL. [Ethanol]

"Alcohol contains not less than 92.3 per cent. by weight, corresponding to 94.9 per cent. by volume, at 15.56° C., of C_2H_5OH." *U. S.*

"Alcohol (90 per cent.) is a mixture of ethyl hydroxide and water containing in 100 parts by volume 90 parts by volume of ethyl hydroxide, C_2H_5OH, and is obtained by the distillation of fermented saccharine liquids." *Br.*

Spiritus Rectificatus, *Br.;* Ethyl alcohol, Ethyl hydroxide, Rectified Spirit; Spiritus Vini Rectificatus vel Rectificatissimus, Alcohol ethylicum, Alcohol Vini; Spirit of Wine; Alcool, *Fr. Cod.;* Esprit de Vin, *Fr.;* Spiritus, *P. G.;* Rectificirter Weingeist, Aethyl alkohol, Alkohol, *G.;* Alcool, Acquavite rectificata, *It.;* Alcohol, Espiritu rectificado de vino, *Sp.*

ALCOHOL DEHYDRATUM. U. S. (Br.)

DEHYDRATED ALCOHOL. Alcohol Dehyd. [Alcohol Absolutum, Dehydrated Ethanol]

"Dehydrated Alcohol contains not less than 99 per cent. by weight of $C_2H_5.OH$." *U. S.* "Absolute Alcohol is ethyl hydroxide, C_2H_5OH, with not more than 1 per cent. by weight of water; obtained by the dehydration of less strong ethylic alcohol, and subsequent distillation." *Br.*

Alcohol Absolutum, *Br.;* Alcohol absolutus, *P. G.;* Absoluter Alkohol, *G.;* Alcool absolu, *Fr.;* Alcool assoluto, *It.;* Alcohol anhidro, *Sp.*

The term dehydrated alcohol should be exclusively applied to this, the strongest commercial form of ethyl alcohol, and the term "absolute alcohol" should be reserved for the theoretical 100 per cent. ethyl hydroxide referred to in the alcohol tables.

ALCOHOL DILUTUM. U. S. (Br.)

DILUTED ALCOHOL. Alcohol Dil.

Alcohol Dil. [Diluted Ethanol]

"Diluted Alcohol contains not less than 41 per cent. and not more than 42 per cent. by weight, corresponding to not less than 48.4 per cent. and not more than 49.5 per cent. by volume, at 15.56° C., of C_2H_5OH." *U. S.*

"The four official liquids obtained by diluting alcohol (90 per cent.) with Distilled Water, contain, respectively, 70, 60, 45, and 20 per cent. of ethyl hydroxide by volume." *Br.*

Spiritus Tenuior, *Br.* 1885, Proof Spirit; Alcool dilué, *Fr.;* Spiritus Dilutus, *P. G.;* Verdünnter Spiritus, Verdünnter Weingeist, *G.*

From the titles and definitions above given, which include all the forms of alcohol recognized by the U. S. and Br. Pharmacopœias, it will be perceived that there are three strengths of alcohol official in the U. S. while the Br. recognizes six. Those preparations of the British Pharmacopœia which are of nearly the same strength and used for similar purposes as solutions official in the U. S. are considered in the same place.

The extensive use of alcohol in pharmacy renders it desirable not only to group the official kinds together here, but to consider each in detail in the subsequent pages.

Alcohol, in the chemical sense, is a peculiar liquid generated for the most part in vegetable juices and infusions by a fermentation, called the "vinous" or alcoholic. The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus, the fermented juice of the grape is called *wine;* of the apple, *cider;* and the fermented infusion of malt and hops, *ale, porter* or *beer.*

With regard to the nature of the liquids susceptible of the vinous fermentation, however various they may be in other respects, one general character prevails; that, namely, of containing sugar in some form or other. It is found, further, that after they have undergone the vinous fermentation the sugar they contain has either wholly or in part disappeared; and it was long believed that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process, and that these, when taken together, are equal in weight to the sugar lost. It was hence inferred that sugar is the subject matter of the changes occurring during the vinous fermentation, and that it is resolved into alcohol and carbon dioxide, $C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$. It has, however, been shown by Pasteur that, along with alcohol and carbon dioxide, glycerin and succinic acid are generated in small amount, and that the process is not so simple as at first supposed. One of the theories earlier held was that some definite intermediate product was always formed between the sugar and the alcohol. Some authorities, including Baeyer and Buchner, believed this product to be lactic acid. One of the more recent views is that of Fernbach, who holds that the intermediate product is *pyruvic acid,* $CH_3COCOOH$, which is capable of being converted into alcohol by yeast, which lactic acid is not. This theory has been further elaborated by Neuberg and Reinfurth (*B. Chem. G.,* 1919, lii, 1677). They state that the first action during fermentation is the rearrangement of the glucose molecule with the formation of one molecule of glyceric acid and one molecule of dihydroxyacetone. These each lose water with the formation of methyl glyoxal ($CH_3.CO.CHO$). This compound is then hydrolized into pyruvic acid and glycerol. The pyruvic acid is then acted upon by a carboxylase in the yeast yielding acetic aldehyde and carbon dioxide. The acetic aldehyde then is reduced to ethyl alcohol.

The accelerating factor in the early stages of alcoholic fermentation is a phosphate, according to Harden and Young (*Proc. Roy. Soc. Lond.,* 1906–1911). This forms a hexose phosphate in the presence of the enzyme.

Much work has been done lately in determining the nutrient factors for the optimum development of the yeast, a combination of phosphates, calcium and magnesium salts and ammonium salts seem to give the best results so far.

Sugar will not undergo the vinous fermentation by itself, but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature by commencing and maintaining the chemical changes. The fermentative change is intimately connected with the multiplication of a microscopic plant, *Saccharomyces cerevisiæ.* Pasteur has shown that the yeast plant lives and grows at the expense of the sugar, which is converted partly into the plant's tissue, partly into alcohol and other products. The proper temperature for conducting vinous fermentation ranges from 15.5° C. to 32.2° C.

Any starchy material may be converted into alcohol if the starch be first converted into soluble carbohydrates, on the commercial scale this is usually accomplished by the use of malt, the diastase of which converts the starch according to the following reactions:

$$(C_6H_{10}O_5)_3 + H_2O = \underset{\text{Dextrin.}}{(C_6H_{10}O_5)_2} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

$$(C_6H_{10}O_5)_3 + 2H_2O = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

The two compounds, *dextrin* and *maltose,* then pass gradually into dextrose, according to the reactions:

$$(C_6H_{10}O_5)_2 + 2H_2O = 2C_6H_{12}O_6$$

$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6$$

Neither dextrin nor maltose is directly fermentable. In this respect they resemble sucrose which must first be inverted before fermentation can occur. Arnoult has succeeded in obtaining alcohol by fermenting sugar (glucose), formed by the action of sulphuric acid on poplar wood sawdust, which yielded from 70 to 80 per cent. of this kind of sugar. Simmson (*Ap. Ztg.,* 1898, 776) obtained 6.5 liters of absolute alcohol from 100 kilogrammes of air dried sawdust. The action of sulphurous acid upon wood fiber has been found by Clássen to be more satisfactory as a saccharifying agent than sulphuric acid, and the process has been successfully used in practice.

The industrial production of alcohol from wood waste or sawdust has not been commercially successful up to the present time. According to S. H. Tomlinson (*Chem. Met. Eng.,* 1918, 552) the difficulty has been due to the unsuitable commercial conditions under which the attempts have been made. He gives cost figures and processes confirming the belief that it is possible to obtain a product of high quality and low cost and states that the unconverted residue of the wood waste, amounting to about 70 per cent., still possesses a high fuel value. T. E. Thorpe (*P. J.,* 1918, 203) directs attention to the value of the seaweeds (*Laminaria* species) as sources of alcohol. He states that 50 kilogrammes of the seaweed dried, converted to sugars with diluted sulphuric acid and then fermented with yeast, will yield 6 liters of alcohol. In Australia a species of palm (*Macrozamia Spiralis*) has been used as a source of alcohol. The roots, which are very starchy, are ground to a fine powder, boiled with water, converted to sugar by the agency of diastatic enzymes and then fermented with yeast. The yield is 45 gallons of alcohol to the ton of material used and the cost is about 4½ pence per gallon of proof spirit (*Commerce Reports,* 1918). In the Philippines distillers are preparing alcohol from the nipa-palm, a swamp plant growing over 100,000 acres in the archipelago (*J. I. E. C.,* 1918, 313).

A valuable table of the sources whence alcohol may be obtained commercially, together with the estimated yield, was published in the *Kew Bulletin* for 1912, No. 3, and will be found reprinted in the *A. Ph. A. Yearbook of Pharmacy* for 1912, p. 354. A similar article also appeared in the *Scientific American* (supplement, May 4, 1918, p. 287) and a more recent one in the *Kew Bulletin,* 1925, v, 193.

In vinous liquors, the alcohol is largely diluted with water, and associated with coloring matter, volatile oil, extractive, ethereal substances, and various acids and salts. In purifying it, advantage is taken of its volatility, which enables it to be separated by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The unrectified distilled product of vinous liquors forms the different *ardent spirits* of commerce. When obtained from wine, it is called *brandy;* from fermented molasses, *rum;* from grain, such as corn, malted barley, or rye, *whisky;* from malted barley and rye meal with hops, and rectified from juniper berries, *Holland gin;* from malted barley, rye, or potatoes, and rectified from turpentine, common *gin;* and from fermented rice, *arrack.* These spirits are of different strengths, that is, contain different proportions of alcohol, and have various peculiarities by which they are distinguished by the taste. Their strength is accurately judged by the specific gravity, which is always less in proportion as their concentration is greater. When they have the sp. gr. 0.920 (0.91984, Drinkwater), they are designated in commerce by the term *proof spirit.* This *English proof spirit* contains about 49 per cent. by weight of alcohol which corresponds to over 57 per cent. by volume. United States *proof spirit* is considerably weaker as United States Custom House and Internal Revenue Service defines the term proof spirit to be alcohol containing 50 per cent. by volume of absolute alcohol at 15.6° C.

Commercial proof spirit is still very far from being pure, being a diluted alcohol, containing about half its weight of water, together with amylic alcohol and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. The average strength of rectified spirit (sp. gr. 0.835), corresponds very nearly with the *Spiritus Rectificatus* of the Br. Pharm. When this is once more cautiously distilled, it may be further purified from water, and the specific gravity attained will be about 0.820, which is the strongest spirit that can be obtained by ordinary distillation, and is practically the pure spirit of the British system of excise. It still, however, contains 11 per cent. of water. In the meanwhile, the spirit, by these repeated distillations, becomes more and more freed from the contaminating oil, called *grain oil* or *fusel oil.* (See *Alcohol Amylicum.*)

The direct synthesis of alcohol from calcium carbide has been commercially accomplished in Switzerland according to the following reactions:

$$CaC_2 \text{ (calcium carbide)} + 2H_2O = Ca(OH_2 + C_2H_2) \text{ (acetylene)}$$

Acetylene may be converted by catalytic action of certain substances into acetaldehyde.

$$C_2H_2 \text{ (acetylene)} + H_2O = CH_3CHO \text{ (acetaldehyde)}$$

The catalytic agents used are sulphuric or phosphoric acids or certain metallic salts.

The acetaldehyde is finally converted into ethyl alcohol by catalytic hydrogenation, using reduced nickel as the catalyst.

$$CH_3COH \text{ (acetaldehyde)} + H_2 = CH_3CH_2OH \text{ (ethyl alcohol)}$$

It is said that by this method, which is being perfected at the Longa Electric Co. at Visp, it will soon be possible to satisfy the total alcohol consumption of Switzerland.

Alcohol can be prepared synthetically from ethylene by simple hydration but it has not been possible thus far to obtain an economic yield of synthetic ethylene, which is one of the normal constituents of coal gas.

Alcohol combines in all proportions with water and ether, and, when diluted with distilled water, preserves its transparency. Its density varies with the proportion of water it contains. (See alcohol tables, Part III.) Its value depends upon the quantity of absolute alcohol contained in it; and, as this is greater in proportion as the specific gravity is less, it is convenient to take the density of a sample as a means of estimating its strength.

This is done by instruments called hydrometers or alcoholometers, which, when allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Each hydrometer degree has a corresponding specific gravity, and, by referring to tables constructed for the purpose, the percentage of absolute alcohol is at once shown. Hydrometer manufacturers graduate instruments showing specific gravity and Baumé's degrees upon the same scale in parallel columns, with a thermometer inserted or taking the place of the bulb; these are exceedingly convenient. Alcoholometers are also constructed to show the alcohol percentage by weight directly, as well as percentage of proof spirit.

The alcoholometer, however, cannot be used to determine the alcoholic strength of wines, flavoring extracts or of any preparations containing more than traces of anything but alcohol and water. For such liquids distillation must be first resorted to. (See *Alcohol Determination,* Part III); also C. R. Hares (*J. A. Ph. A.,* 1918, 594).

Alcohol is used enormously in the arts as a solvent and for other purposes, and the U. S. government has established suitable regulations permitting the proper use of alcohol in manufacturing and forbidding its sale as a beverage. The liquid treated so that it is rendered unfit for use in beverages is termed *denatured alcohol.* Among the denaturants thus permitted are tartar emetic, salicylic acid, quinine sulphate, colocynth extract, diethylphthalate, brucine and iso-propyl alcohol. Owing to the dishonesty of some manufacturers of toilet preparations and perfumes these supplies are occasionally diverted from their original purpose and turned over for sale for medicinal use or for beverage purposes, either with or without rectification. Even the most careful attempts at rectification sometimes fail to remove all traces of the denaturant and careful tests are necessary to determine the fitness of a sample of alcohol for use in manufacturing operations. The French excise directs that alcohol should be denatured or deprived of its natural properties by the addition of 500 cc. of petroleum benzin and 1 Gm. of malachite green to each hectoliter; it has been found, however, that the color can be destroyed by calcium hypochlorite.

The U. S. Internal Revenue Department has authorized the use of a number of formulas for denaturing alcohol, but it must be prepared under the supervision of an official of the Department, in special plants. Some of these formulas provide an alcohol for burning purposes or for use as special solvents, others are the preliminary steps to manufacturing processes, such as a mixture of sulphuric acid and alcohol for the subsequent production of ether, while other formulas have now been authorized which are identical with official formulas, such as tincture of iodine, soap liniment, etc., thus making it possible to have these products manufactured from duty-free alcohol at greatly reduced cost. These preparations may therefore be purchased from large dealers at prices which are less than the cost of the raw material if bought through the usual channels of trade.

The dangerous properties of methyl alcohol when taken internally caused the Committee of Revision of the U. S. P. to introduce a test for determining the presence or absence of methyl alcohol, which is sometimes used as an adulterant for alcohol. See *Methanol,* Part II, also *U. S. D.,* 19th ed., p. 105.

Alcohol is capable of dissolving a great number of substances as, for example, sulphur and phosphorus in small quantity, iodine and ammonia freely, and the hydroxides of potassium, sodium, and lithium, but not the carbonates of these metals. Among organic substances, it is a solvent of most of the vegetable alkaloids, urea, tannic, citric, and tartaric acids, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil which is abundantly soluble in it. It reacts chemically with some acids, forming the ethyl esters, but with others acts only as a solvent. All deliquescent salts are soluble in alcohol, except potassium carbonate; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it. It dissolves ammonium chloride, and most of the chlorides readily soluble in water; also some nitrates, but none of the metallic sulphates.

A method of detecting alcohol in small proportions has been proposed by Carstanjin. The liquid supposed to contain it, having been mixed with platinum black in a small flask, is heated to 51.1° C., well shaken, and filtered. To the filtrate a few drops of solution of potassium hydroxide are added, and the liquor evaporated to dryness on a water bath. The residue is then heated with a little arsenic trioxide, when, if alcohol be present, a garlicky odor will be perceived, owing to the production of cacodyl. According to Nickles, however, propylic alcohol will produce the same result. (*A. J. P.,* 1865, p. 334.) A very delicate test for small quantities of alcohol is that of Lieben as modified by Hager. (*Zeit. An. Chem.,* ix, 492.) It depends on the fact that alcohol under the influence of iodine and an alkali yields iodoform, CHI_3, the properties of which are very characteristic. To 10 cc. of the clear suspected liquid five or six drops of a 10 per cent. solution of potassium or sodium hydroxide are added, and the liquid is warmed to about 50° C. A solution of potassium iodide fully saturated with free iodine is next added drop by drop, with agitation, until the liquid becomes permanently yellowish-brown, when it is carefully decolorized by a further cautious addition of the caustic alkali solution. If alcohol be present, iodoform is gradually deposited at the bottom of the tube in yellow crystals of the flat hexagonal type seen in snowflake crystals, which, after standing, may be transferred to a microscope-slide and examined with a lens. Spirit diluted with 2000 parts of water, when treated as above and allowed to stand twelve hours, gives a distinct dust-like deposit of iodoform. Unfortunately, the above delicate reaction is not peculiar to alcohol, being produced by acetone, aldehyde, propylic and butylic alcohols, various ethers, etc. On the other hand, it is not given by pure methyl or amyl alcohol, chloroform, chloral, glycerin, or ether, nor by acetic, formic, or oxalic acids. (Allen, *Com. Org. Anal.*)

A specific reaction for alcohol, which is not interfered with by impurities nor by methyl alcohol or acetone, has been proposed by A. Toninelli (*P. J.,* xciii, 47), as follows: The reagents required are (1) 1.5 Gm. of pure crystal dinitritoluol, dissolved in 200 cc. of a mixture of 1 part of carbon disulphide and 2 parts of ether; (2) 12 Gm. of iodine, dissolved in 100 cc. of ether; (3) 40 Gm. of potassium hydroxide, dissolved in 100 cc. of distilled water.

Into a 10 cc. graduated glass-stoppered tube are introduced 2 cc. of the liquid to be tested, 2 cc. of the iodine solution, and after shaking and allowing to stand for two minutes, 4 cc. of potassium hydroxide solution is added and the mixture shaken until decolorized. Finally, 2 cc. of the dinitritoluol reagent is added with vigorous shaking, the graduated tube is placed upon a white surface and the upper layer closely observed. If ethyl alcohol is present in quantity sufficient to react, an orange-yellow color is developed which passes through various shades, terminating in intense garnet red. With as little as 3 per cent. alcohol the color is a light rose. Some of the higher alcohols give somewhat similar effects, but are readily removed by salting out and shaking with petroleum benzin.

Alcohol tables will be found in Part III, which will give the specific gravities of the various strengths of alcoholic liquids. The temperature at which the specific gravities of these liquids is taken was not changed to 25° C. in the U. S. P. X, as it was for most liquids, because the temperature 15.6° C. was the one adopted by the U. S. government and still retained by it, for all of the national legal requirements.

ALCOHOL DEHYDRATUM. *Absolute Alcohol, Anhydrous Alcohol, Ethylic Alcohol.*—No process is given in the U. S. Pharmacopœia for the preparation of dehydrated alcohol; the definition given, however, is "A liquid containing not less than 99 per cent. by weight of $C_2H_5.OH$." *U. S.* The following is the process of the Br. Pharmacopœia (1885): "Rectified Spirit, 1 pint [Imp. meas.]; Carbonate of Potassium, anhydrous, 2 ounces [av.]; Chloride of Calcium, fused, a sufficiency. Add the carbonate of potassium to the spirit in a stoppered bottle, and macerate for twenty-four hours with frequent agitation. Put the chloride of calcium into a covered crucible, and subject it to a red heat for half an hour; then pour the fused salt on to a clean stone slab, cover it quickly with an inverted porcelain dish, and when it has congealed, break it up into small fragments and enclose in a dry stoppered bottle. Put one pound [av.] of this fused chloride of calcium into a flask, pour over it the spirit decanted from the carbonate of potassium, and, closing the mouth of the flask with a cork, shake them together and allow them to stand for twenty-four hours with repeated agitation. Then attaching a dry condenser closely connected with a receiver from which free access of air is excluded, and applying the flame of a lamp to the flask, distil about two fluidounces [Imp. meas.], which should be returned to the flask, after which the distillation is to be continued until fifteen fluidounces [Imp. meas.] have been recovered." *Br.*, 1885. By the term absolute alcohol is meant pure alcohol, entirely free from water. In this state it cannot be obtained by ordinary distillation; even with a column still the purest alcohol obtainable contains 5 per cent. of water. To separate this it is customary to have recourse to substances having a very strong affinity for water, sufficient not only to abstract it from the alcohol, but to retain it at a temperature at which alcohol will distil over.

In all cases, before decanting or distilling, the alcohol must be digested for two or three days with lime, at a temperature between 35° and 37.7° C. Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the calcium hydroxide formed will yield up its water to the alcohol, and weaken the distilled product. J. Lawrence Smith procures an alcohol of 98 to 100 per cent. by macerating 3 pints of alcohol, 94 per cent., in a four-pint bottle with about six troy ounces of well burned lime; well corked and agitated at intervals for ten days, the strengthened alcohol, at the end of this time, is drawn off by a siphon, and may be freed, if desired, of the small trace of lime by redistillation. Yvon prepares absolute alcohol by treating strong alcohol with powdered calcium carbide. L. W. Winkler recommends metallic calcium for dehydrating alcohol. About 20 Gm. of calcium are required for one liter of alcohol.

Properties.—Dehydrated alcohol is a colorless, volatile liquid, of an agreeable odor and burning taste. It boils at 78.4° C., and is congealed at –130.5° C. Its sp. gr. is 0.7978 at 68° C., according to Regnault; 0.79381 at 60° C., according to Drinkwater; 0.794 (equivalent to 99.95 per cent. of ethyl hydroxide by volume and by weight) to 0.7969 (equivalent to 99.4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight), by the British Pharmacopœia; while E. R. Squibb has shown that pure alcohol is obtainable of as low a density as 0.7935, and possibly lower. (*Ephem.*, ii, p. 522.) The sp. gr. of its vapor is 1.59.

Description and Physical Properties.—"A transparent, colorless, mobile, and volatile liquid, having a characteristic odor, and a burning taste. It is very hygroscopic. Specific gravity: not above 0.798 at 15.56° C. (the U. S. Government standard temperature for alcohol). Shake 10 cc. of Dehydrated Alcohol in a stoppered tube with about 0.5 Gm. of powdered anhydrous cupric sulphate: the latter does not become blue (*water*). In other respects Dehydrated Alcohol has the properties of and complies with the tests for purity under *Alcohol.*

"Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

"Specific gravity from 0.794 (equivalent to 99.95 per cent. of ethyl hydroxide by volume and by weight) to 0.7969 (equivalent to 99.4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight). Very volatile and hygroscopic at ordinary temperatures. Anhydrous *copper sulphate* shaken occasionally during two or three hours in a well-closed vessel with about fifty times its weight of Absolute Alcohol does not assume a decidedly blue color (absence of excess of water). Free from the impurities indicated under 'Spiritus Rectificatus,' and resembling it in other general characters." *Br.*

The tests usually given to prove the absence of water by dropping into the absolute alcohol anhydrous barium oxide or anhydrous copper sulphate are not reliable, as Squibb has demonstrated that when half of one per cent. of water was added to absolute alcohol no change in either the barium oxide or the anhydrous copper sulphate took place. Görgeu's test of forming a clear solution when mixed with an equal bulk of pure benzene is more delicate, but a test for determining the presence of as little as one per cent. of water is needed. Dehydrated alcohol should be free from fusel oil. Dehydrated alcohol burns with a pale flame without residue, the products being carbon dioxide and water. Its vapor, passed through a porcelain tube filled with pumice stone and heated to redness, yields carbon, gaseous hydrocarbons, aldehyde, naphthalene, benzene, phenol, and various other substances. (Berthelot.) It unites in all proportions with ether and water. Its union with water is attended by condensation and a rise of temperature. When 54 volumes of alcohol are mixed with 46 of water, the decrease of volume is at the maximum, amounting to 3.6 per cent. For further details see paper by H. C. Wood, Jr., *J. A. Ph. A.*, 1919, viii, 730.

ALCOHOL. *U. S. Alcohol,* sp. gr. 0.816 at 15.6° C.—This is the so-called "95 per cent. alcohol" of commerce (or 94.9 per cent. by volume); it was an official preparation of the Dublin College, which gave a formula for its preparation, and stated its sp. gr. at 0.818. The British Pharmacopœia (1914), under the title "Spiritus Rectificatus," recognizes alcohol of 90 per cent. by volume or 85.68 by weight, slightly weaker than U. S. P. alcohol.

It is described as follows:

Description and Physical Properties.—" A transparent, colorless, mobile, and volatile liquid. It has a slight, characteristic odor, and a burning taste. It is inflammable. Alcohol is miscible with water without any trace of cloudiness; also miscible with ether and with chloroform.

" Specific gravity: not above 0.816 at 15.56° C. (the U. S. Government standard temperature for Alcohol). Alcohol is readily volatilized even at low temperatures and boils at about 78° C. Alcohol diluted with an equal volume of distilled water does not affect the color of blue or red litmus paper previously moistened with water. Evaporate 40 cc. of Alcohol in a platinum or porcelain dish on a water bath, and dry at 100° C.: the residue does not exceed 0.001 Gm. Mix 10 cc. of Alcohol with 5 cc. of distilled water and 1 cc. of glycerin, and allow the mixture to evaporate spontaneously from clean, odorless blotting paper: no foreign odor is perceptible when the last traces of the Alcohol leave the paper (*fusel oil constituents*). Allow 25 cc. of Alcohol to evaporate spontaneously in a porcelain dish carefully protected from dust, until the surface of the dish is barely moist: no red or brown color is produced upon the addition of a few drops of sulphuric acid (*amyl alcohol or non-volatile, carbonizable organic impurities, etc.*). On mixing 10 cc. of Alcohol in a test tube with 5 cc. of potassium hydroxide T.S., the liquid does not at once assume a yellow color (*aldehyde or oak tannin*). Shake 20 cc. of Alcohol in a clean, glass-stoppered bottle with 1 cc. of silver nitrate T.S., and allow the mixture to stand in diffused daylight for 6 hours: the mixture does not become more than faintly opalescent, or acquire more than a faint brownish tint (*organic impurities, aldehyde, etc.*). Dilute the Alcohol with water to contain about 5 per cent. by volume of ethyl alcohol. To 5 cc. of this dilute alcohol contained in a test tube of 20 cc. capacity, add 0.5 cc. of phosphoric acid and 2 cc. of a 3 per cent. aqueous solution of potassium permanganate, and allow the mixture to stand for ten minutes. Add 1 cc. of an aqueous 10 per cent. solution of oxalic acid, and allow to stand until the liquid is a transparent brown. Now add 5 cc. of a diluted and cooled sulphuric acid, prepared by mixing 3 volumes of distilled water and 1 volume of sulphuric acid, add 5 cc. of freshly prepared fuchsin-sulphurous acid T.S., mix well, and allow to stand for ten minutes. At the end of this time the solution, when observed against a white background, may have a reddish or pale green tint, but not a distinct blue or violet color (*methanol*). A mixture of 5 cc. of Alcohol, 2 cc. of sodium hydroxide T.S., and 5 drops of a freshly prepared aqueous solution of sodium nitroprusside (1 in 50), rendered slightly acid with acetic acid, shows no violet tint within one minute (*acetone*). Alcohol, diluted with an equal volume of water, does not respond to the tests for *alkaloids, diethylphthalate, formaldehyde, isopropyl alcohol,* and *phenols* described under *Spiritus Frumenti.*

" Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

" Specific gravity 0.8337. It contains 85.68 per cent. by weight of ethyl hydroxide, C_2H_5-OH, and 14.32 per cent. by weight of water. Burns with a blue smokeless flame. Leaves no residue on evaporation (absence of non-volatile matter). Remains clear when mixed with *water* (absence of oily or resinous substances). A little exposed on clean white filter paper leaves no unpleasant smell after the alcohol has evaporated (absence of fusel oil and allied impurities). 100 cc., with 2 cc. of *N/10 solution of silver nitrate,* exposed for twenty-four hours to bright light and then decanted from the black powder which has formed, undergo no further change when again exposed to light with more *N/10 solution of silver nitrate* (absence of more than traces of amylic alcohol and of other organic impurities). When mixed with half its volume of an aqueous solution (1 in 5) of *sodium hydroxide,* the mixture does not immediately darken in color (absence of more than traces of aldehyde). No immediate darkening in color is caused by the addition of *solution of ammonia* (absence of tannic acid, excess of aldehyde, and other organic impurities)." *Br.*

On a large scale, alcohol of this strength is now prepared in the United States, very abundantly, by simple distillation by means of a modified distillatory apparatus known as a " still and column." The modification consists in substituting for a single refrigerated receiver a series of receivers, kept at such temperatures that, in the first of them, the aqueous vapor shall condense with comparatively little of the alcoholic, which, as it passes through the successive condensers, is more and more deprived of water, until, when condensed in the last, it yields a spirit at least as strong as the official Alcohol of the sp. gr. 0.816. At the same time that the spirit is thus strengthened, it becomes, through the principle of fractionation which the process introduces, more and more freed from fusel oil, until almost wholly deprived of it.

Commercial alcohol, though of standard strength, may still be impregnated with sufficient fusel oil to modify the characteristic odor.

The present *alcohol* of the U. S. P. corresponds to that formerly recognized as *Alcohol Deodoratum* (*Deodorized Alcohol*), U. S., 1890, and may be used for many purposes for which ordinary commercial alcohol would be unsuited, such as the solution of volatile oils and essences having delicate odors, the manufacture of compound spirits, etc.

Deodorized alcohol is manufactured under Atwood's process, in which manganic acid or potassium or sodium permanganate is used to destroy fusel oil and other foreign substances. This alcohol withstands the tests of silver nitrate and sulphuric acid remarkably well. Pure fused sodium acetate has been proposed as a substance particularly adapted to retain fusel oil, and has been used by adding it to the alcohol to be rectified in the proportion of about 10 pounds to the barrel of forty-five gallons, and redistilling. The purification of alcohol is accomplished, according to Schmitt, by taking crude alcohol containing 30 per cent. by volume, adding potassium carbonate (not enough to cause two layers to form), and agitating with pure petroleum benzin; this solvent removes completely the fusel oil from the alcohol. After separating the light layer, potassium carbonate is added to the alcohol in sufficient quantity to form two layers, the lower one consisting of a saturated solution of potassium carbonate, the upper one of 94 per cent. alcohol containing a small quantity of potassium carbonate. The alcohol layer is siphoned off and mixed with just sufficient strong sulphuric acid to precipitate the potassium salt as sulphate, which is insoluble in alcohol of 94 per cent., and which can then be removed. Alcohol purified in this manner, without distillation, it is stated, cannot be distinguished from that purified by the usual method. F. G. Earl recommends the following method, which has the advantage of requiring no special apparatus. "Rub four drachms of powdered unslaked lime with two drachms of powdered alum intimately; add one gallon (95 per cent.) alcohol, and shake well, then add one fluidrachm of spirit of nitrous ether, set aside for seven days, and filter through animal charcoal." (*C. D.*, 1895, 35.) *Perfumer's alcohol* can now be had, which is very much cleaner than *cologne spirit,* as the purest alcohol attainable was formerly called. It is termed perfumer's alcohol because it was found necessary to prepare a very high grade of alcohol for those who need a solvent for fine odors, on the score of economy and to insure greater excellence of product.

ALCOHOL DILUTUM. *U. S.*—Specific gravity from 0.935 to 0.937 at 15.6° C. and from 0.930 to 0.932 at 25° C.

Diluted alcohol is officially made by mixing equal measures of alcohol and water together.

"Alcohol 500 cc. Distilled Water 500 cc. Measure the alcohol and water at the same temperature, and mix them. If the two liquids are measured at the temperature of 25° C., the mixture when cooled to the same temperature will measure about 970 cc." *U. S.*

The British Pharmacopœia (1914) no longer uses the titles "Spiritus Tenuior" or "Proof Spirit" for diluted alcohol, but admits four official liquids under the name of diluted alcohol, as follows:

"1. **Alcohol (70 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *three hundred and ten and a half* (310.5) *millilitres* of Distilled Water. Specific gravity 0.8899.

"2. **Alcohol (60 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *five hundred and thirty-six and a half* (536.5) *millilitres* of Distilled Water. Specific gravity 0.9134.

"3. **Alcohol (45 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *one thousand and fifty-three and a half* (more accurately 1053.4) *millilitres* of Distilled Water. Specific gravity 0.9435.

"4. **Alcohol (20 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *three thousand five hundred and fifty-eight* (3558.0) *millilitres* of Distilled Water. Specific gravity 0.9760." *Br.*

This is a convenient pharmaceutical method of providing suitable menstrua for making tinctures, fluidextracts, and other galenical preparations, which have been adopted by the British Pharmacopœia.

"**Tests for Identity and Purity.**—Diluted Alcohol has a specific gravity of from 0.935 to 0.937 at 15.56° C. (the U. S. Government standard temperature for alcohol). It complies with the purity tests under *Alcohol,* allowance being made for the difference in strength and the presence of water, the boiling point being omitted.

"Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

Uses.—The local action of alcohol is mildly irritant, feebly anesthetic and distinctly germicidal. The most favorable concentration for the destructive action on bacteria is from 60 to 70 per cent.; either higher or lower concentrations are less efficient. This amount of alcohol is capable of destroying most of the pathogenic micro-organisms within a relatively short time, but some of the more resistant spore-bearing germs are not killed even by prolonged exposure.

Alcohol belongs, physiologically as well as chemically, to the group of aliphatic narcotics. In large doses it will produce a condition of coma which is precisely analogous to the anesthesia produced by ether. A number of authors, however, have maintained that in small quantity it acts as a cerebral excitant. There are arguments in favor of this view, and one may not speak too dogmatically on the subject, but the weight of evidence to-day indicates that any dose of alcohol sufficient to affect the system at all, lessens, rather than increases, intellectual activity.

Krapelin (*Ueber d. Beeinflussung einf. psychischer Vorgänge durch einige Arzneimittel,* Jena, 1892) found that doses of 30 cc. or more depressed all psychical processes, but with very small quantities there was a preliminary slight facilitation lasting 20 or 30 minutes and followed by a secondary depression, even after doses as small as 7.5 Gm. Dodge and Benedict (*Proc. Nat. Acid. Science,* 1915, 1) find that both the spinal and cerebral reactions are depressed by a single dose of 30 cc. (See also Benedict, *A. J. P.,* 1925, xcvii, 413.)

Small doses of alcohol seem to stimulate respiration (see Hooker, *J. P. Ex. T.,* 1919, x, 121), but large quantities are depressant. Scarborough (*J. P. Ex. T.,* 1921, xvii, 129) finds that the effect of alcohol upon muscle tissue is to cause a temporary increase of excitability which is followed by a period of lessened response.

The question of its effects on the circulation has been the subject of much study and dispute. When administered in moderate quantity, it usually does not produce any marked change in the blood pressure, although occasionally there may be some elevation. On the other hand, the rapidity of the flow of blood through the vessels is distinctly accelerated. This concordination of effects can be explained only by simultaneous increase in the cardiac action and dilatation of the blood vessels. While there is considerable difference of opinion on this subject we believe that the evidence is strong that quantities of alcohol equivalent to not over one-half an ounce for the ordinary man, increase the amplitude of the cardiac contractions. The experiments of Dixon (*J. P.*, 1907, xxxv) indicate that this effect is most marked when the heart is partially exhausted. The widening of the blood vessels is most noticeable in the vessels of the skin. Large quantities of alcohol produce a marked fall in the blood pressure which is due not only to paralysis of the vasomotor mechanism, but also to a depressant action upon the heart.

When a moderate quantity of alcohol is ingested, from 90 to 95 per cent. is completely oxidized in the system, only traces of the drug being recoverable from either the urine or breath. The oxidization of this amount of hydrocarbon material must of necessity yield energy. Some have, however, attempted to maintain that this energy was not utilizable by the animal economy. The experiments of Atwater and Benedict (*Memoirs of the National Academy of Science*, 1902, vii) and others, seem to demonstrate beyond cavil that small amounts of alcohol are entirely capable of replacing an equivalent portion of the hydrocarbon foodstuffs. But the amount of alcohol which the system is capable of oxidizing is rather limited, and if the administered dose be increased the drug begins to appear unchanged, or only partially oxidized, in the urine and in the exhalations. Whether the presence of unaltered alcohol in the bodily fluids hastens or retards metabolism is still an unsettled question. It seems, however, to be fairly well established that in some way it distorts metabolism, and that the oxidation, especially of purin-containing bodies, is not so complete as in the normal animal.

Alcohol has a marked influence upon gastric and probably also intestinal digestion. In small amounts it does not influence the activity of the peptic ferments, although concentrations of 10 per cent. or over greatly reduce or completely destroy the enzymic activity of pepsin. It has long been recognized that the swallowing of small quantities of alcoholic liquors increases the flow of gastric juice. While this is in part probably due to the local irritation of the mucous membrane of the stomach there is also some central mechanism involved, as an increase in the gastric and pancreatic secretions has been shown after the intravenous or rectal administration of alcohol. After section of the vagi or their paralysis by atropine this increase in the digestive secretions does not occur. (For review of literature on the effects of alcohol on digestion, see Salant, *A. J. Phys.*, 1907, xvii, p. 409.)

Alcohol is used locally as a mild counter irritant and as a germicide. Internally it is used (1) to excite the heart, (2) as a stimulant to digestion (3) as an accessory food and (4) for its narcotic effects.

As a circulatory stimulant there is no doubt that in the past too much confidence has been placed in alcohol. Nevertheless if used circumspectly it is often of great value. It is used especially when it is desired to tide the patient over for a limited period of time, as in cases of depressant *poisonings.* It must never be forgotten in this connection that large doses are depressant to the heart; while a small amount of alcohol may prove useful in cases of *snake bite,* it is no exaggeration to say that the injudicious exhibition of this drug has been responsible for as many deaths in rattlesnake bites as the venom itself. In the circulatory failure due to anesthetics it should be sedulously avoided; on account of its close chemical relation to both ether and chloroform it acts as a synergist rather than an antagonist to these poisons. The use of alcohol in *infectious fevers,* especially *typhoid fever,* involves a large number of factors concerning some of which we have at present no definite knowledge. While it seems to be well established that in large doses alcohol diminishes the resistance of the body to bacterial invasion the influence of small quantities upon the vital resistance is as yet a matter of dispute. The impairment of digestion, which is so universal an accompaniment of these diseases, suggests the use of alcohol both as a stimulant to gastric secretion and as an accessory food. While febrile patients are capable of burning up larger quantities of alcohol than normal individuals, if given too freely the unoxidized alcohol circulating in the blood may prove injurious. An alcoholic odor to the breath is generally a sign that the patient is receiving more than he can oxidize. Many believe that the mild narcotic action of alcohol is also of service in preserving the vitality in these adynamic states.

By dilating the vessels of the skin alcohol tends to increase the sweat and is frequently used as an aid to more powerful diaphoretic measures in the abortion of mild infections, such as *acute coryza.*

Locally it is of service for its disinfectant action not only in cleansing the hands of the surgeon but also as a dressing for local inflammations and *wounds.* Although not infrequently employed for the sterilization of surgical instruments the uncertainty of its effects against spore forming organisms makes it very unreliable for this purpose. Recently it has been widely employed for its local paralytic influence when injected into nerve tissue, as in *sciatica,* but especially in that most intractable disorder *tic douloureux.*

Raw alcohol is rarely used internally, preference being always shown for one of the alcoholic beverages, such as whiskey, brandy, or wine.

The purer forms of alcohol, whether strong or diluted, are employed almost exclusively in pharmacy; as in the preparation of medicines, such as ether, into the composition of which they enter; for the preservation of organic substances; in the extraction of the active principles of drugs, as in the tinctures; for dissolving bodies soluble in alcohol much more readily than in water, or insoluble in the latter fluid; and for other pharmaceutical purposes. Diluted alcohol is employed as an addition to some infusions and decoctions, and to some of the distilled waters; in order to preserve them from decomposition; as a menstruum for extracting the virtues of plants, preparatory to the formation of extracts and syrups; and in preparing many of the spirits, and a few of the medicated wines. But it is in forming the tinctures that diluted alcohol is chiefly used. Some of these are made with official alcohol (rectified spirit), but the majority with mixtures of alcohol and water of different percentages. As diluted alcohol contains more than half its weight of water, it is well fitted for acting on organic substances the virtues of which are partly soluble in water and partly in alcohol.

Toxicology.—The symptoms of acute alcohol poisoning are unfortunately so widely known that detailed description is unnecessary, but the striking similarity between the symptoms of alcoholic intoxication and ether anesthesia is worthy of note; in the more profound stages of alcoholism there is the complete loss of consciousness and of sensation, the muscular relaxation, and the slow respiration, which are characteristic of the ether narcosis. It should not be forgotten that acute alcohol poison may, and frequently does, end fatally. The treatment consists in the immediate evacuation of the stomach, the maintenance of the bodily temperature by the use of external heat, the use of respiratory stimulants, such as strychnine, cocaine and atropine, and of cardiac stimulants, as ammonia and digitalis.

The habitual use of alcoholic beverages may lead to profound degenerations of the various internal organs, especially the stomach, liver, and kidney. The changes may be either sclerotic or fatty. Besides these there are often marked symptoms of serious nervous diseases, but whether the latter are organic or toxic is as yet unsettled.

ALETRIS. N. F.

ALETRIS Aletr. [Star Grass, Unicorn Root]

"Aletris consists of the dried rhizome and roots of *Aletris farinosa* Linné (Fam. *Liliaceæ*). Aletris contains not more than 5 per cent. of foreign organic matter and yields not more than 10 per cent. of acid-insoluble ash." *N. F.*

Unicorn Root, Star Grass, Blazing Star, Mealy Starwort, Colic Root, Ague Root; Alétris farineux, *Fr.;* Mehlige Aletris, *G.*

Probably because of the fact that the English names "blazing star" and "starwort" have been applied to the aletris as well as to the chamælirium, this drug has commonly been confused with helonias. Both the plants and the roots of these two drugs are so different that they do not occur as intentional adulterants of each other but helonias is not infrequently substituted for aletris.

Aletris farinosa L. or *True Unicorn Root* is a perennial acaulescent herb indigenous to sandy and grassy woods of the Eastern United States and extending westward to Arkansas and Minnesota. It is characterized by possessing a horizontal to slightly oblique grayish-yellow to grayish-brown rhizome, from the sides and lower face of which emanate many tough, wiry, pale yellow or whitish, fibrous rootlets. From this rhizome there arises a spreading rosette of thin lanceolate foliage leaves and later, through the center of the rosette, a naked slender scape, bearing a spike-like raceme of small, white, tubular flowers. The fruit is an ovoid, beaked capsule inclosed in a roughened, mealy looking perianth.

The aerial portion of *Aletris* may be distinguished from the similar part of *Chamælirium* or *False Unicorn Root* (which yields the drug *Helonias*) by the following characters: The flowers of *Aletris* are perfect, whereas those of *Chamælirium* are dioecious; the perianth of *Aletris* is gamophyllous and distinctly roughened, whereas that of *Chamælirium* is composed of six distinct segments and smooth; the capsule of *Aletris* is ovoid and beaked and enclosed in the roughened perianth, whereas that of *Chamælirium* is ellipsoidal and devoid of a perianth investment; all of the foliage leaves of *Aletris* are grass-like and radical, whereas *Chamælirium* possesses radical foliage leaves which are spatulate and cauline foliage leaves which are lanceolate.

The rhizome systems of *Aletris* and *Chamælirium* show marked dissimilarities. Thus, the rhizomes of *Aletris* are generally horizontal and without annulations, while those of *Chamælirium* are generally vertical and annulate, the fracture of the former being strong, starchy and fibrous and of the latter horny and resinous; moreover, the rootlets of *Aletris* frequently have portions of their cortex abraded exposing a reddish-brown endodermis, whereas no such condition is evident in *Chamælirium.* The taste of *Aletris* is starchy, sweetish and bitter, whereas that of *Chamælirium* is strongly bitter.

Most of the aletris now on the market is collected in the Carolinas and Tennessee.

UNIVERSITY OF ILLINOIS LIBRARY-CHEMISTRY

Description and Physical Properties.—"*Unground Aletris.*—Rhizome horizontal or slightly oblique, nearly cylindrical or laterally compressed above, 2 to 4 cm. in length and 5 to 12 mm. in diameter; externally grayish-brown; upper portion with circular stem scars 3 to 7 mm. in diameter and with numerous leaf bases; the sides and lower portion with numerous tough, wiry, whitish roots which are reddish brown when the cortex is removed and are more or less flexuose and provided with short branches; fracture short; internally light brown, cortex 1 to 2 mm. in thickness, central cylinder with numerous twisted and branching fibrovascular bundles. Odor slight, acetous; taste sweetish, bitter.

"*Structure.*—Rhizome with epidermis bearing numerous glandular hairs with a short one-celled stalk and a rounded head; tissue composed chiefly of parenchyma cells filled with starch grains or raphides of calcium oxalate; numerous irregularly distributed and branching groups of tracheæ the latter with reticulate or simple pores and surrounded by several layers of lignified cells, these cells with thick walls and large oblique pores; endodermis usually absent except in the older portion of the rhizome where it occasionally occurs as an interrupted zone. Root with a distinct endodermis composed of one layer of cells with thick, deep yellow, closely lamellated walls; cortex composed chiefly of parenchyma and readily separated from the central stele, the latter containing numerous lignified fibers, a few tracheæ and sieve cells.

"*Powdered Aletris.*—Light gray to yellowish brown; numerous orange-yellow thick-walled fibers with tapering pointed ends and simple or branching pores; fragments of tracheæ with reticulate or simple pores and associated with lignified cells; numerous fragments of parenchyma containing starch grains, the latter spherical or ellipsoidal from 0.003 to 0.016 mm. in diameter, and numerous raphides of calcium oxalate in bundles or individual crystals, the latter from 0.025 to 0.50 mm. in length; fragments of epidermal tissue frequently bearing glandular hairs." *N. F.*

As far as we know, aletris has never been submitted to chemical examination.

Uses.—There is no reason to suspect that aletris possesses any therapeutic virtues other than those of a simple bitter. As suggested by its popular name of "colic root," it has, however, been used to considerable extent for the purpose of expelling *flatulence.* Probably because of its confusion with helonias it has been employed in the treatment of various uterine disorders but without clinical justification.

Dose, twenty to thirty grains (1.3–2.0 Gm.).

Off. Prep.—Fluidextractum Aletridis, *N. F.;* Elixir Viburni Opuli Compositum, *N. F.;* Elixir Aletridis Compositum, *N. F.*

ALLIUM. N. F.

GARLIC

"Garlic is the fresh bulb of *Allium sativum* Linné (Fam. *Liliaceæ*)." *N. F.*

Ail, *Fr.;* Knoblauch, *G.*

The genus *Allium* includes a large number of species, of which nearly seventy are indigenous in this country. Many, and perhaps all, of these species contain volatile oil upon which their activity depends. The cultivated garlic, of which the bulbs are official in the N. F., is *Allium sativum* L., for which, according to Griffith, *A. canadense* L., has been substituted and found efficient.

Allium sativum, L., or *English garlic,* is a perennial plant with numerous bulbs which have a common membranous covering, from the base of which the fibers that constitute the proper root descend. The stem is simple, and rises about two feet. The leaves are long, flat, keeled and grass-like, and sheathe the lower half of the stem. At the termination of the stem is a cluster of purple flowers and bulbels mingled together, and enclosed in a pointed spathe, which opens on one side and withers. The flowers make their appearance in July. This species of garlic is indigenous to Europe. It grows wild in Sicily, Italy, and the south of France. The bulbs, or so-called cloves, are usually six or eight in number, oblong or wedge-shaped, and covered with dry membranous scales with a pungent odor and a disagreeable and acrid taste.

Description and Physical Properties.—"*Whole Garlic.*—Bulb subglobular, 4 to 6 cm. in diameter, compound, with 8 to 15 bulbels surrounded by whitish, membranaceous scales and attached to a flattened circular base, the latter with numerous yellowish white roots; bulbels ovoid in transverse section 3- to 4-sided, the outer surface convex, apex acute and narrowed into a thread-like fibrous portion, base truncate; each bulbel covered by whitish, membranaceous, scale-like leaves, beneath which is a light brown or pinkish, thin and coriaceous layer of epidermis, cohering but easily separable from the solid portion of the bulbel. Odor when broken or bruised powerfully alliaceous, taste intensely pungent and persistent.

"*Structure.*—Bulbel with three distinct portions; (a) the large fleshy scale consisting chiefly of parenchyma enclosing scattered vascular bundles; epidermis in both ventral and dorsal surfaces of small tabular cells; (b) a middle layer nearly circular in outline, about 0.750 mm. in diameter, the tissues resembling those of the outer fleshy scale, but the cells containing numerous yellowish brown plastids; (c) an innermost bright green layer consisting of a single leaf folded lengthwise along the midrib so that the ventral surfaces lie close together. The membranaceous scales, dry leaf and root remains should be removed before Garlic is used for the manufacture of pharmaceutical preparations." *N. F.*

Constituents.—Such medicinal value as garlic may possess is undoubtedly due to its volatile oil.

The *oil of garlic* is of a dark brownish-yellow color, heavier than water, and decomposed at its boiling temperature. It may be purified by repeated distillation in a salt water bath, and is then lighter than water, of a pale yellow color, and not decomposed by boiling. Semmler obtained from garlic bulbs 0.09 per cent. of the volatile oil, sp. gr. at 14.5° C. 1.0525; it was yellow, having an intense odor and optically inactive. By fractional distillation he obtained four products, $C_6H_{12}S_2$, $C_6H_{10}S_2$, $C_6H_{10}S_3$, and $C_6H_{10}S_4$, which decomposed during distillation, and hence could only be obtained by distillation *in vacuo*. The oil, according to Semmler, is free from allyl sulphide, the latter having the sp. gr. 0.8991. (*A. Pharm.*, 1892, p. 434.) The impure oil has an exceedingly pungent odor and a strong acrid taste, and, when applied to the skin, produces much irritation and sometimes even blisters. The pure oil combines with silver nitrate, forming a precipitate soluble in heated alcohol and afterwards separating in crystals. Besides this oil, fresh garlic, according to Cadet de Gassicourt, contains, in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Legrange mentions among its constituents sulphur, a saccharine matter, and a small quantity of starch. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried, it serves as a lute for porcelain. It has the medicinal properties of the bulbs. Water, alcohol, and vinegar extract the virtues of garlic. Protracted boiling renders it inert. According to Semmler (*A. Pharm.*, 1887, p. 927), *Allium ursinum* contains a volatile oil which consists mainly of *vinyl-sulphide*, C_4H_6S or $(C_2H_3)_2S$.

Uses.—Among the ancients garlic was credited with curative virtues in an extraordinarily large variety of diseases. At the present time its medical employment is limited chiefly to pulmonary conditions such as *chronic bronchitis*, especially with an asthmatic tendency, and sometimes *whooping-cough*. Minchin (*Pract.*, Feb., 1918) has revived the ancient idea of its value as an internal antiseptic and lauds it as a remedy for *diphtheria, tuberculosis* and other infectious diseases. Loeper and DeBray (*Bull. Soc. Hôp.*, 1921, xxxvii, 1032), from experiments upon both human beings and dogs, reach the conclusion that the tincture of garlic causes a fall in blood pressure which is most marked in cases of hypertension. They also find that it brings about a leucocytosis. There is no doubt that the oil of garlic is absorbed through the alimentary tract and eliminated partly through the lungs and partly through the urine. Garlic is also occasionally employed as an anthelmintic, especially in domestic practice.

Externally it is employed as a rubefacient and stimulant to the nervous system especially in cases of young children. In *catarrhal pneumonia* bruised garlic cloves are sometimes applied as a poultice to the lungs, partly because of their counterirritant effect and partly for endermic absorption.

The expressed juice of garlic is sometimes employed in doses of one-half fluidrachm (2 cc.) but the most popular preparation is the syrup, which is recognized by the N. F., and may be given in doses of one to two teaspoonfuls (4–8 cc.).

The fresh bulb is occasionally exhibited in substance in *doses* of from one-half to two drachms (2 to 8 Gm.).

Off. Prep.—Syrupus Allii, *N. F.*

ALOE. U. S. (Br.)

ALOE

"Aloe is the inspissated juice of the leaves of *Aloe Perryi* Baker, known in commerce as Socotrine Aloe; of *Aloe vera* Linné, known in commerce as Curaçao Aloe; or of *Aloe ferox* Miller, known in commerce as Cape Aloe (Fam. *Liliaceæ*). Aloe yields not more than 4 per cent. of ash, not more than 10 per cent. of moisture, and not less than 50 per cent. of water-soluble extractive." *U. S.* "Aloes is the juice that flows from the transversely cut leaves of Aloe chinensis, *Baker,* Aloe Perryi, *Baker,* and probably other species of Aloe, evaporated to dryness. Known in commerce as Curaçao aloes, Socotrine aloes, or Zanzibar aloes." *Br.*

Aloe Barbadensis; Aloe Socotrina; Aloès, *Fr.*; Socotora oder Socotrinische Aloe, *G.*; Barbados Aloe, *G.*; Musebber, *Ar.*; Acibar Sucotrino, *Sp.*

Most plants belonging to the genus *Aloe* are capable of yielding a bitter juice which is laxative and there is little doubt that in many cases a commercial aloe exported from one country is the product of several species.

1. *Aloe Perryi,* J. G. Baker, *Tr. Linn. Soc.*, xxviii. The true Socotrine aloe plant was first described from specimens sent to Kew Gardens by Wykeham Perry, and was subsequently found by Balfour, of Edinburgh, growing abundantly upon the island of Socotra, especially in the limestone tracts, from the sea level to an altitude of 3000 feet; along with it, but much less abundant, was a dwarf species with spotted leaves. It is a perennial herb indigenous to the island of Socotra. It has a trunk one foot high which bears on its summit a dense rosette of pale green or reddish, succulent, lanceolate leaves which are somewhat striate but not mottled. They are channeled above, convex below and show brown-tipped, marginal spines. From the center of the leaf rosette there extends a long raceme of tubular, reddish flowers which later turn yellow. The fruit is a membranous capsule.

The proper aloetic juice was formerly thought to exist in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely; but, according to E. Robiquet, who made elaborate researches in relation to this drug, these vessels are air ducts, and the juice flows in the intercellular passages between them. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. After condensation by artificial or natural heat the aloe juice is poured into gourds, more commonly boxes, or into monkey skins, allowed to harden and sent into commerce.

2. *Aloe vera* L. (*A. barbadensis* Miel.).—This species, which is the source of Curaçao aloe, has a very short, woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous green color, when young, irregularly mottled with white spots, flat on the upper surface, convex beneath, and armed with hard, pale spines, distant from each other, and perpendicular to the margin. It has bright yellow flowers arranged in a spicate inflorescence. *A. vera* is a native of Southeastern Europe, Northern Africa, and Madagascar. It is cultivated in Italy, Sicily, Malta, and especially in the West Indies, where it contributes largely to furnish the Barbados aloe.

3. *Aloe chinensis* Baker.—This species was introduced from China into the Dutch Colonies of Curaçao by W. Anderson, in 1817. It is Asiatic in origin and probably a variety of *A. vera* as shown by Haworth. The leaves of *A. chinensis* are not more than half the length of those in *A. vera,* and are more or less copiously spotted on the dorsal surface as in *A. abyssinica* Baker. The flowers have a strong and decidedly unpleasant odor; and occur in loose racemes, the stamens being much shorter than in *A. barbadensis.* Holmes suggests that *A. chinensis* may be a native of Africa, Arabia or India. Engler considers that *A. chinensis* is merely a form related to *A. vera.* (Baker, in *J. L. S.,* xviii, p. 161; Holmes, *P. J.,* xxi, p. 205.)

4. *A. ferox* Miller, one of the three species yielding Cape aloe, is one of the tallest species of the genus. It has a forked stem ten to fifteen feet long, four to six inches in diameter; furnished at the top with a dense rosette containing thirty to fifty leaves, which are lanceolate, one and one-half to two feet long, very rigid, with copious prickles on back and face, the purplish margin armed with reddish brown-tipped, deltoid or cuspidate prickles one-eighth to one-sixth of an inch long. Its inflorescence consists of a panicle of tubular, striped whitish flowers.

5. *Aloe africana* Mill. has a simple tall trunk which bears on its summit a few, triangular-oblong, glaucous, green leaves with large horny marginal teeth. Its flowers are tubular and yellow and are borne on a candelabra-like panicle. It is a native of the Cape Colony.

6. *Aloe spicata* Baker (*A. Eru* var. *cornuta* Berger) is a tall, branched aloe indigenous to tropical Africa. It possesses pale glossy, fleshy leaves with white blotches and a panicle of campanulate yellow flowers.

According to L. Pappe, Cape aloe of poor quality is obtained from *A. africana* and *A. plicatilis,* of Miller; while in Lindley's *Flora Medica, A. purpurascens* Haworth, *A. arborescens* Mill., *A. Commelyni* Willd., and *A. multiformis* are all said to contribute to commercial Cape aloes.

Commercial History and Varieties.—Three chief varieties of aloe have been known in comparatively recent commerce: Socotrine, Barbados or Curaçao, and Cape.

SOCOTRINE ALOE.—This variety appears to have been the original aloe, having been produced in the island of Socotra at least as early as the time of Alexander the Great, 333 B.C., who is said to have sent a commission to investigate its manufacture. This form of aloe under the title of "Aloes Socotrina" alone is official in the Spanish Pharmacopœia. It is said to be derived from *Aloe vera* Mill., *A. spicata* Thunb., *A. ferox* L., *A. arborescens* Mill., and *A. linguæformis* L., and other species of aloes.

It is stated that the production of aloe in Arabia was formerly a government monopoly, but that at present it is entirely free to the inhabitants. The leaves, which are cut at any time of year, are allowed to drain into a goat's or sheep's skin, and the gathered juice permitted to evaporate spontaneously. In the course of about one month, when it has become thick and viscid, it is known by the Arabic name of *Jâyef Gesheeshah;* several weeks subsequently when it has become hard, it is called *Jâyef Kasahul.* Due to its exposure throughout the long process of desiccation, all the varieties of Socotrine aloes contain much foreign matter, which, according to E. R. Squibb, amounts to from 7 to 22 per cent. of the bulk.

Socotrine aloe is brought from the island of Socotra, the east coast of Africa and from the Arabian coast by Arab traders to Bombay and exported in barrels, kegs, goats' skins, or tins to London whence it is shipped to the United States. It is usually very wet, containing up to 20 per cent. of moisture.

The best Socotrine aloe occurs in pieces verying from a dark ruby-red to a yellowish or reddish-brown, more or less semi-transparent, with a glossy surface and a smooth or ragged but not conchoidal fracture, and yielding a bright golden-yellow powder. Its odor is peculiar, almost fragrant, especially developed by breathing upon the aloe, and its bitter, disagreeable taste has a somewhat aromatic tang. The poorest variety of Socotrine aloe, *Mocha aloes* of the East, is soft, dark, and malodorous. Some of the drug supplied American dealers in recent years has consisted of this variety. Even the finest Socotrine aloe may consist of an orange or yellow colored distinctly fragrant, semi-liquid mass.

ZANZIBAR ALOE is a hepatic variety of

Socotrine aloe made by slow evaporation of the juice. It occurs in liver-brown masses, with a dull, waxy but nearly smooth and even fracture, a characteristic odor and a nauseous, bitter taste. It is poured into skins which are packed in cases for shipment. The variability of Socotrine aloe probably depends upon not only different methods of preparation but a different origin. Both Zanzibar and true Socotrine Aloes "are opaque even in small splinters, though they exhibit, when mounted in almond oil and examined under the microscope, numerous minute crystals embedded in a transparent, dark yellowish-brown mass, and impart to *nitric acid* a reddish- or yellowish-brown color." *Br.*, 1900.

CURAÇAO OR WEST INDIAN ALOE.—This aloe, which is produced in the Dutch West Indian Islands, chiefly in the islands of Aruba, Bonaire and Curaçao, appears not to have entered commerce extensively before the early part of the 19th century, but at present constitutes a very large proportion of commercial aloe. It occurs chiefly in three forms; first, an opaque, brittle aloe, showing abundant crystals under the microscope, and sold in gourds usually as Barbados aloe; second, aloes having an appearance like the first variety but sold in cases; third, glossy Curaçao or Capey Curaçao aloe, which occurs in cases and is glossy and transparent. This variety may become opaque upon long storage due to the gradual crystallization of the aloin. Small fragments show a garnet-red color.

Curaçao aloe is apparently produced by the following species: *A. vera* (L.) Webb, *A. vulgaris* Lam., *A. spicata* L., and *A. socatrina* Lam., all of which have been introduced into the island (see *P. J.*, Jan., Sept., 1890), although E. M. Holmes believes it to be at least in part the product of *A. chinensis* Baker.

Curaçao aloe is collected in the Dutch West Indies by workers during the early spring. The leaves are cut off at their bases and placed cut end downward in V-shaped troughs which are arranged on an incline. The juice, in trickling from the leaves, runs down the sides of the trough and through an aperture at its lower end into a receptacle beneath. As the receptacles are filled with the juice, their contents are poured into a cask and either evaporated spontaneously or by boiling in copper vessels. As soon as the juice has thickened to the proper consistency, it is poured into gourd shells or boxes and allowed to harden. This aloes is shipped direct to the United States from Aruba, Curaçao and Bonaire.

According to P. van der Wielden, shining Curaçao aloe dissolves completely in nitric acid with the production of a red color, while the dull Curaçao aloe, giving the same color reaction, fails to entirely dissolve. Kremel gives a method to distinguish Curaçao aloe from other kinds by adding to it a little cupric sulphate solution, then some saturated solution of common salt, which makes the color an intense carmine. The reaction is due to *cuproaloin.* (*C. D.*, 1895, 759.) Curaçao aloe is sometimes found in the markets which has been deprived of its aloin; this fraudulent product is then sold as Cape aloes; the odor of the Curaçao variety still remains.

CAPE ALOE.—This variety is from *Aloe ferox, Aloe africana* and *Aloe spicata.* The general method of collecting Cape aloe is to allow the excised leaves to drain into a sheep's skin, which has been so placed in a hole in the ground as to force the juice to collect in the center. Later this juice is poured into tins, subsequently boiled down over a fire in iron pans, and when sufficiently concentrated, poured into boxes or barrels and allowed to harden. In these containers it is shipped from Mossel Bay and Port Elizabeth to Cape Town, thence to Europe and America. Cape aloe differs from Socotrine aloe, especially in its brilliant conchoidal fracture and peculiar odor, which is strong, but neither nauseous nor aromatic. When freshly broken it has a very dark olive or greenish color approaching to black, presents a smooth, bright, almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow color, and, being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. Cape aloe, when quite hard, is very brittle and readily powdered; but in very hot weather it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. This variety alone is official in the Swiss, German, and Austrian Pharmacopœias.

Uganda or *crown aloe* is a brand of Cape aloe formerly produced by manufacturers who bought the aloe juice from the collectors, allowed it to undergo a slight fermentation, and dried it in the sun in wooden troughs. It was sent into commerce in bags containing coarse or fine powder, or chips, and in bricks wrapped in red paper; it has a very bitter, aromatic taste and a strongly aromatic odor. The bricks are of a hepatic brown color, with a resinous fracture, which has a bronzy-gold luster by reflected light. Splinters are translucent, but not garnet-red. With nitric acid it forms a brown solution, gradually changing through dull brownish-yellow to a deep green color. Uganda aloe is now practically obsolete.

BARBADOS ALOE.—This aloe appears to have been brought to London as early as 1693, and to have reached its greatest commercial abundance in the year 1843, when 4227 gourds of it are said to have been exported from Barbados, a gourd containing from twenty to sixty pounds. Occasionally small quantities of Barbados aloe are on the American markets. Most of the Barbados aloe was produced from *A. vera,* although *A. socotrina, A. purpurascens,* and *A. arborescens* are said to have been cultivated.

The method of obtaining Barbados aloe seems to have varied at different periods of time, and possibly in different portions of the island. According to various authors the lower ends of the freshly cut leaves were put into wooden V-shaped troughs, and the exuding juice collected and dried in the sun or boiled in copper pans; again, a decoction of the chopped-up leaves was boiled to the proper consistency; in either case, when the liquor had become so thick that it hardened on cooling, it was poured into calabashes or gourds.

Barbados aloe, as formerly supplied, varied in color from very dark blackish-brown through reddish-brown and liver-colored to orange-brown. It yielded a dull olive-yellow powder, of a disagreeable, even nauseous odor, and it was described in the British Pharmacopœia as follows: "Fracture either dull and waxy, in which case small splinters are opaque; or smooth and glassy, in which case the splinters are transparent; the opaque variety examined under the microscope exhibits numerous minute crystals embedded in a transparent mass." *Br.,* 1898.

"Mixed with nitric acid, it acquires a red color. Barbados Aloes is not colored, or acquires only a light bluish-green tint, on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloe*)." *U. S.,* 1890.

According to Marais, Barbados aloe could be distinguished by the fact that its solution in distilled water, 1 to 100,000 parts, yielded on the addition of gold chloride or of tincture of iodine a fine rose color, all other varieties of aloes producing with the reagents named either a feeble color of slow development, or no change of color whatever.

Unofficial Varieties.—Besides the official varieties of aloe several allied drugs have appeared from time to time in commerce.

Natal aloe is a variety coming from Natal on the southeast coast of Africa, the origin of which is not definitely ascertained but is possibly *A. succotrina,* Garsault. It occurs in irregular pieces, with a fracture much less shining than that of Cape aloe and a totally different color, having a greenish slate hue. It yields a greenish-brown powder, which has the odor of Cape aloe. It is less soluble than Cape aloe, and has a peculiar composition, which will be adverted to under the chemistry of the drug.

Besides the chief varieties of aloe, others are, or have been, known in the market. *Hepatic aloe,* as well as *fetid, caballine* or *horse aloe,* have no proper claim to be considered distinct varieties, being simply inferior aloe of various origins, the first liver-colored, the second blackish and fetid and full of impurities. *Jafferabad aloe,* supposed to be the same as *Mocha aloe* (*A. J. P.,* 1881, 175), has been shown to be the product of *A. abyssinica* Lam., and is said by Shenstone to contain *b*-barbaloin. (*A. J. P.,* 1883, 92.) Aloe made in India from the *A. vera* is known as *Musambra aloe.* It appears to be a very inferior variety, and rarely, if ever, reaches Europe. (*P. J.,* Aug., 1889.) Occasionally aloe is found on the market in which the aloin has been removed. Noyes has reported the presence of pea flour in the powdered drug.

It is evident that the labels under which aloe are largely sold often have little or no connection with the place of production, or with the variety of aloes in the package. This fact has probably come about through the indifference of retail druggists to the variety of the aloe which they are using, an indifference largely due to their common habit of buying aloe in powder. Wilbert (*A. J. P.,* 1903) proposed that aloes should be classified as follows:

Aloe A.—Containing barbaloin; responds to Bornträger's test for emodin, but does not give a distinct red color with nitric acid, or with Klunge's test.

Aloe B.—Containing isobarbaloin with barbaloin; responds to Bornträger's test for emodin, and also has a deep red color with strong nitric acid, or with Klunge's test.

The commercial aloes are sometimes divided into two groups: 1. Those which are shiny and amorphous, as Cape aloe, and 2. Those which are of a dull color and crystalline. To this latter group most of the other aloes belong. They are also grouped geographically as follows. 1. South African aloe, including Cape and Natal. 2. East African aloe, including Socotrine, the brown and black Zanzibar aloes and Madagascar aloe. 3. The West Indian aloe which includes the Curaçao, Barbados and Jamaica varieties. 4. The East Indian aloe which includes Jafferabad and Musumbra aloes. The official description is limited to the three principal varieties, viz., Socotrine, Curaçao and Cape aloes.

Description and Physical Properties.—"*Unground Socotrine Aloe.*—In yellowish-brown to blackish-brown, opaque, smooth and glistening masses; fractured surface somewhat conchoidal; odor characteristic.

"*Unground Curaçao Aloe.*—In orange to blackish-brown, opaque masses; fractured surface uneven, waxy, somewhat resinous; odor characteristic, disagreeable.

"*Unground Cape Aloe.*—In reddish-brown masses, usually covered with a yellowish powder, or in thin, transparent fragments, of a reddish-brown color; fracture smooth and glassy; odor characteristic, sour and disagreeable. The taste of each variety of Aloe is nauseous and very bitter.

"*Powdered Aloe.*—Yellowish-brown to dark reddish-brown; mounted in a bland, expressed oil, it appears as yellowish to reddish-brown angular or irregular fragments, the depth of color depending to some extent on the thickness of the fragments.

"Powdered Aloe dissolves in nitric acid with effervescence, Socotrine Aloe forming a yellowish to reddish-brown solution; Curaçao Aloe, a deep red solution; Cape Aloe a reddish-brown solution, changing to purplish-brown and finally to greenish. Intimately mix in a flask or bottle about 1 Gm. of powdered Aloe, accurately weighed, with 25 cc. of cold water, shake occasionally during two hours, transfer to a filter, tared after it has been dried over sulphuric acid, and wash with sufficient cold water to make the filtrate measure 100 cc.: the residue on the filter after drying over sulphuric acid should not exceed 50 per cent. of the weight of powdered Aloe taken. The color of the filtrate, viewed in the bulb of a 100 cc. volumetric flask, is light yellowish-brown with Socotrine Aloe, reddish-brown with Curaçao Aloe, and yellowish with Cape Aloe. The filtrate darkens upon standing. To 5 cc. of the filtrate mentioned above, add 2 cc. of nitric acid: the mixture is of a yellowish to yellowish-brown color with Socotrine Aloe; a deep red color with Curaçao Aloe; a reddish-brown color, changing to vivid green, with Cape Aloe. To 5 cc. of the filtrate mentioned above, add 45 cc. of water and 20 cc. of sodium borate solution (1 in 20): a greenish fluorescence results and, upon standing, the liquid acquires a brownish color. To 10 cc. of the filtrate mentioned above, add 90 cc. of water and shake with 10 cc. of benzene: upon separating the benzene layer, and adding to it 5 cc. of ammonia T.S., a permanent, deep rose color is produced in the lower layer.

"Add 1 Gm. of Aloe to 50 cc. of alcohol, gently heat the mixture and then cool it: a nearly clear solution is obtained (*gum or inorganic impurities*).

"**Assay.**—Process as directed under water-soluble extractive." *U. S.*

The 1914 British Pharmacopœia gives the following description: "In hard masses, varying in color from yellowish-brown to dark or chocolate-brown. Fractured surface dull, waxy and uniform (Curaçao and Zanzibar aloes), or uneven and somewhat porous (Socotrine aloes). Small splinters examined under the microscope exhibit minute crystals embedded in a transparent mass. Characteristic odor; taste nauseous and bitter. The solution obtained by dissolving 0.1 gramme of Aloes in 10 millilitres of boiling *water* and adding 0.5 gramme of *purified borax* acquires a green fluorescence. *Nitric acid* dropped on a little crushed Aloes acquires a reddish-brown color (Socotrine and Zanzibar aloes), or a crimson color (Curaçao aloes). Almost entirely soluble in *alcohol* (60 per cent.). Loss on drying at 100° C. not more than 10 per cent. Ash not more than 5 per cent." *Br.*

Constituents.—The purgative properties of the official varieties of aloe are chiefly due to the glucoside *barbaloin,* which according to Lèger has the formula $C_{21}H_{20}O_9$ (*P. J.,* 1902, 21), but the Br. 1898 assigned the formula $C_{16}H_{16}O_7.3H_2O$. This seems to be identical with the substances previously known as *socaloin* and *capaloin.* In Curaçao and Barbados aloes there is present also an isomeric compound, *isobarbaloin.* Both of these principles are crystalline. In Cape aloe there occurs also an amorphous, isomeric substance known as *beta-barbaloin.* Tschirch (*B. P. G.,* 1898, viii, Heft 6) has shown that when barbaloin is boiled with an alcoholic solution of hydrochloric acid it yields *emodin* $C_{15}H_{10}O_5$ or *trioxymethyl-anthraquinone* (see under *Rheum*). There is present also another anthraquinone derivative known as *aloe-emodin* and a bitter resin and various water soluble substances of which little is known. The resin of the Curaçao aloe consists of *barbaloresinotannol* combined with cinnamic acid; that of Cape and Socotrine aloes of *capaloresinotannol* combined with paracumaric acid.

The active principle of Natal aloe is different from that of the official varieties and is known as *nataloin.* It may be distinguished from the official aloin by Histed's reaction. A drop of nitric acid on a porcelain slab gives, with a few particles of barbaloin or nataloin, a vivid crimson (rapidly fading in the case of barbaloin, but permanent with nataloin unless heat be applied), but produces little effect with socaloin. To distinguish barbaloin from nataloin, test each by adding a minute quantity to a drop or two of sulphuric acid, then allowing the *vapor* from a rod touched with fuming nitric acid to pass over the surface. Barbaloin (and socaloin) will undergo no change, but nataloin will assume a fine blue. (*Pharmacographia,* 2d ed., p. 688.) The Curaçao aloe yields from 10 to 25 per cent. of glucosides of which about half is barbaloin and half isobarbaloin. Cape aloe and Socotrine aloe yield from 4 to 9 per cent. of barbaloin with only traces of isobarbaloin. Since barbaloin is found in almost all varieties, the significance of the prefix "barb" is misleading. The only aloe in which it does not occur is that of Natal.

The substance described by Robiquet under the name of *aloëtin* was probably an impure form of aloin.

Hugo Bornträger asserted that one part of aloe in 5000 can be detected in the following manner. A little of the suspected liquid is shaken with about twice its bulk of benzin, which is allowed to separate, decanted, and shaken with a few drops of stronger water of ammonia. On separation the ammonia will be of a clear red color. With solids a tincture should first be made. According to R. H. Groves (*P. J.,* 3d ser., xi, 1045), this test will never succeed with a less concentration than 1 part in 250, and with some aloes 1 in 100, and is due to the tannin-like substance of aloes; he also states that extreme care is necessary to have the benzin solution perfectly clear. (*P. J.,* 1885, p. 633.) No satisfactory method for assaying aloe for the aloin content has yet been devised. For that suggested by Hager, see *A. J. P.*, 1885, p. 237.

A color reaction delicate enough to detect Barbados aloe in the proportion of 1 part in 10,000 has been proposed by C. E. Staly. (*C. D.*, 1916, 68.) If a freshly prepared solution of potassium ferricyanide be added to a cold aqueous solution of the aloe a pink color is produced.

R. A. Cripps and T. S. Dymond have given the testing of aloes a lengthy investigation, and they recommend the following method. Place one grain of substance in a glass mortar standing on white paper, now add sixteen drops of strong sulphuric acid and triturate until dissolved, then add four drops of nitric acid, sp. gr. 1.42, and then one ounce of distilled water. If aloes be present, a color varying from deep orange to crimson will be produced, according to the kind of aloes that has been used; the color is deepened by the addition of ammonia. The table below is taken from the paper of Bainbridge and Morrow. (*P. J.*, Jan., 1890.) Under the heading of Kew Specimens are given the results obtained with juice of aloe plants grown in Kew Gardens.

Commercial Specimens.	HNO_3.	H_2SO_4 and Vapor of HNO_3.	Cripps and Dymond Test.	C. and D. Test with NH_4OH.	Bromine Test.	$FeCl_3$.
Hepatic aloe	Reddish-brown.	Nil.	Orange-red.	Intense brownish-red.	Nil.	All varieties of aloes give an olive-green coloration with the above reagent.
True Socotrine	Reddish-brown.	Nil.	Orange-red.	Intense brownish-red.	Nil.	
Commercial Socotrine	Faint crimson	Nil.	Crimson.	Deep claret.	Nil.	
Cape	Permanent green after standing a few minutes.	Nil.	Orange-red.	Pale claret.	Nil.	
Curaçao	Evanescent crimson.	Nil.	Crimson.	Intense claret.	Nil.	
Natal	Permanent crimson.	Deep blue.	Deep crimson.	Intense brownish-red.	Nil.	
Barbados	Crimson soon fading.	Slight bluish-green occasionally.	Crimson.	Deep claret.	Nil.	
KEW SPECIMENS.						
Aloe ferox	Evanescent crimson.	Green.	Pale yellow.	Red.	Violet.	
—*socotrina*	Permanent crimson.	Deep blue.	Crimson.	Intense brownish-red.	Deep purplish-red.	
—*vera*	Nil.	Slight green.			Nil.	
—*Perryi*	Nil.	Nil.			Nil.	
—*purpurascens*	Crimson fading to light red.	Nil.			Violet.	
—*platylepis*	Nil.	Nil.			Nil.	
—*arborescens*, var. *frutescens*	Nil.	Nil.			Nil.	
—*africana*	Evanescent red, changing after a few minutes to green.	Nil.	Orange-red.	Pale claret.	Nil.	
—*chinensis*	Nil.	Nil.			Nil.	

Aloe yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the inert portion is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by oxidizing the aloin and rendering it insoluble. The alkalies, their carbonates, and soap alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odor of the drug.

A method for the detection of aloe in mixtures containing other cathartic drugs, such as rhubarb, cascara, etc., has been described by Mossley (*Chem. and Drug.*, 1913, 915). The method depends upon the precipitation of the oxymethyl anthraquinones, which usually interfere in such identification tests, and the subsequent detection of aloes by the addition of bromine T.S., which precipitates aloin, and the green fluorescence produced with aloes by borax.

E. M. Bailey (*A. J. P.*, 1915, 145) and Hubbard (*J. I. E. C.*, 1917, ix, 518) have devised other methods of distinguishing, by means of color reactions applied to the mixed anthraquinone derivatives, between a number of commonly used purgative drugs including chrysarobin, frangula, rhubarb, senna and aloes.

Uses.—Aloe was known to the ancients, being cultivated in the island of Socotra as far back as the time of Alexander the Great, and is mentioned in the works of Dioscorides and of Celsus. Its cathartic action is due to a stimulation of peristalsis, especially in the larger bowel, probably the result of a local irritant effect upon the mucous membrane, although there is some evidence that it exercises a specific stimulant effect upon unstriped muscles. As its action is largely limited to the colon it is not to be recommended in those conditions in which it is desirable to clean out the whole alimentary canal, and as its effect is largely the result of local irritation it should be avoided in inflammatory conditions of the intestine. In *chronic constipation*, however, especially when dependent upon an atonic condition of the lower bowel, it is one of the most useful laxatives that we possess. Many believe that it possesses a direct tonic action, not only evacuating the bowel of its contents but encouraging a restoration toward normal conditions. The presence of bile in the bowel seems in some way to be essential for the best effects of this drug, and in those cases in which this secretion is lacking it is well to exhibit some preparation of bile in conjunction with the aloes. Soap also appears to enhance the cathartic action of this drug. It was formerly almost universally believed that aloes possessed emmenagogue properties and it was accordingly largely used in the treatment of various forms of *amenorrhea.* It is, however, extremely doubtful whether it exercises any action upon the pelvic organs which is not attributable to its cathartic effects. Aloe was formerly regarded as a vulnerary but its use for this purpose has entirely disappeared except as an ingredient in compound tincture of benzoin.

Those substances only are incompatible with aloes which alter or precipitate the soluble matter, as the insoluble portion is without action upon the system. Among these is the infusion of galls, which we have found, probably through its tannic acid, to afford a copious precipitate with an aqueous solution of aloe. It is said that such a mixture will keep a long time, even for a period of several months, without mouldiness or putrescence, though it becomes ropy.

Crude aloes is rarely used in human medicine, but may be given in *doses* of from two to ten grains (0.13–0.65 Gm.).

ALOINUM. U. S., Br.

ALOIN Aloin.

"A pentoside or mixture of pentosides obtained from aloe. It varies in chemical composition, and in physical and chemical properties according to the variety of aloe from which it is obtained." *U. S.* "Aloin is a crystalline principle obtained from aloes." *Br.*

This is a mixture of the glucosides known by the chemist as barbaloin and isobarbaloin (see under *Aloe*).

Preparation.—Aloin may be prepared by W. A. Tilden's process as follows: 1 part of aloes is dissolved in 10 parts of boiling water acidulated with hydrochloric acid, and allowed to cool. The liquid is then decanted from resinous matter, evaporated to about 2 parts, and set aside two weeks for crystals to form; the liquid portion is poured off, the crystals pressed, and the adherent resinous matter separated by shaking with acetic ether, which dissolves the resin. This process answers fairly well for obtaining aloin from Barbados or Curaçao aloe. Aloin from Socotrine aloe is best obtained by digesting it in 3 parts of alcohol for 24 hours, then transferring to a water bath, and boiling for 2 hours. After cooling, the liquid is filtered and set aside to crystallize. The crystals are washed with a little alcohol and dried. The yield is about 10 per cent. (H. C. Plenge, *A. J. P.,* 1884, p. 507.) According to Lewis Ough (*C. D.,* 1892, 837) Tilden's process, modified, affords the best results; Barbados aloe yielded 12 per cent. of aloin. Schäfer obtains from 15 to 30 per cent. of crystallized aloin from commercial aloe by the following process: 50 Gm. of aloe dissolved in 300 cc. of hot water is slightly acidulated with hydrochloric acid. The solution, after standing (for the resins to separate), is decanted, mixed with 50 cc. of 20 per cent. ammonia water, followed by a solution of 15 Gm. of calcium chloride in 30 cc. of water. The liquid is agitated and the aloin-calcium compound which separates is collected, drained, and mixed in a mortar with a slight excess of hydrochloric acid; the mixture of aloin and calcium chloride is dissolved in the smallest possible quantity of boiling water, filtered, and the filtrate cooled by means of ice; the aloin crystallizes. (*P. J.,* 1897, p. 287.) For further tests for aloin see under *Aloe.*

Description and Physical Properties.—"A lemon-yellow to dark yellow microcrystalline powder, or minute crystals. It is odorless, or has a slight odor of aloe. The taste is intensely bitter. Aloin darkens on exposure to light and air. Aloin is soluble in water, alcohol and acetone, the degree of solubility varying with its composition. It is also soluble in ammonia water and in solutions of alkali hydroxides, forming red solutions (or yellow solutions that soon become red) having a green fluorescence. It is slightly soluble in ether.

"A saturated aqueous solution of Aloin is yellow, changing to brown on standing. The solution is neutral or not more than faintly acid to litmus paper. Aloin is rapidly decomposed when added to alkaline solutions; when mixed with acid solutions, decomposition is slower. A drop of ferric chloride T.S. added to an alcoholic solution of Aloin produces a brownish-green color.

"Ash: not more than 0.5 per cent. Shake 1 Gm. of Aloin with 10 cc. of benzene for one minute and filter: the filtrate imparts not more than a faint, pink color to an equal volume of 5 per cent. ammonia water when shaken with it (*emodin*). Dissolve 1 Gm. of Aloin, accurately weighed, in 120 cc. of distilled water at 25° C. by shaking frequently during two hours. Collect the insoluble residue, if any, on a filter, or a Gooch crucible, tared after it has been dried at 100° C., and wash the residue with 25 cc. of distilled water: this residue when dried at 100° C. does not exceed 1.5 per cent.

"Preserve in well-closed containers, protected from light." *U. S.*

"A pale yellow, microcrystalline powder. Almost inodorous; taste intensely bitter. Almost entirely soluble in 130 parts of *water*, in 18 parts of *alcohol* (90 per cent.), and in 50 parts of *acetone;* very sparingly soluble in *ether, chloroform,* and *benzene;* readily soluble in dilute *solution of ammonia*, the liquid becoming red and acquiring a greenish-red fluorescence. 0.5 gramme of Aloin gently warmed with 25 millilitres of *water* forms an almost clear solution; the filtered liquid remains clear on cooling, but on long standing slowly deposits pale yellow crystals of Aloin. One drop of *solution of copper sulphate* added to 20 millilitres of an aqueous solution (1 in 1000) of Aloin produces a bright yellow coloration, which is changed to red by the addition of 0.5 millilitre of a saturated aqueous solution of *sodium chloride,* and to violet on the further addition of 1 millilitre of *alcohol* (90 per cent.). No appreciable ash." *Br.*

Aloin of commerce is frequently contaminated with resin, indicating want of care in manufacturing. According to Serre (*D. C.,* 1895, 8), this may be detected by finely powdering one grain of the sample, shaking it in a test tube with 20 cc. of water, and allowing it to stand one minute. The solution should be perfectly clear. See also paper by C. H. LaWall. (*Proc. Penn. Pharm. Assoc.,* 1895, 92.)

Uses.—The actions of aloin upon the system are precisely the same as that of aloe to which it is superior because of the variations of potency of the crude drug, as well as on account of the smaller dose of aloin. Moyer (*A. E. P. P.,* xxviii) has shown that when given hypodermically it is capable of producing purgative effects but it is never employed practically in this manner. There is a marked difference in the cathartic activity of the various kinds of aloin. Barbaloin is more powerful than socaloin and, according to Moyer, nataloin generally fails to purge in man, although acting energetically upon dogs. Aloin is one of the most frequently employed of laxatives in *chronic constipation,* especially in combination with belladonna and strychnine.

Dose, one-sixth to one grain (0.01–0.065 Gm.).

ALSTONIA. Br.

ALSTONIA

"Alstonia is the dried bark of Alstonia scholaris, *R. Br.,* and also of Alstonia constricta, *F. Muell.*" *Br.*

Dita Bark; Australian Fever Bark; Bitter Bark. Dita Rinde *G.;* Pali Mari, *Ind.*

Under Alstonia the British Pharmacopœia recognizes the dried barks of *Alstonia scholaris* (L.) R. Br. (*Echites scholaris* L.), of India and the Philippine Islands, and *Alstonia constricta* F. Muell., of Australia, two apocynaceous trees whose barks are quite dissimilar in appearance, and, as far as our present knowledge goes, contain different alkaloids. These barks are respectively described as follows:

"Bark of Alstonia scholaris usually in irregular fragments, three to twelve millimeters thick; texture somewhat spongy, fracture short and coarse; external layer unevenly rough and fissured, brownish-grey with occasional blackish spots; internal layer bright buff. Transverse section shows numerous small medullary rays in inner layer. Almost odorless; taste bitter. Bark of Alstonia constricta usually in curved pieces or quills about sixty millimeters wide, and twelve millimeters thick. Periderm from two and a half to six millimeters thick, rusty brown, strongly rugose, with large deeply fissured reticulations. Bark internally cinnamon-brown, with strong, coarse longitudinal striæ. Transverse section shows dark-brown periderm covering the inner orange-brown tissues, in which numerous small shining particles can be seen with a lens. Fracture short and granular in outer layers, fibrous in inner. Slight aromatic odor; taste very bitter." *Br.*

From the bark of *Alstonia scholaris* M. Gruppe extracted an uncrystallizable, hygroscopic, bitter principle, *ditaine.* (*P. J.,* Aug., 1875.) Harnack (*B. Chem. G.,* 1878) first obtained ditaine in pure crystallized form, and gave it the formula $C_{20}H_{30}O_4N_2$. O. Hesse (*P. J.,* Oct. 23, 1880) finds in dita the following principles: three alkaloids: *ditamine,* $C_{16}H_{19}O_2N$, the relative amount of which he estimates at 0.04 per cent.; *echitamine,* $C_{22}H_{28}O_4N_2 + H_2O$ (identical, according to Hesse, with Harnack's ditaine); and *echitenine,* $C_{20}H_{27}O_4N$. Of these, the second is the strongest base, and resembles ammonia in its chemical characters; Hesse considers it with one molecule of water to form the hydroxide of a strong basic radical, *echitammonium,* $C_{22}H_{29}O_4N_2$. The solutions of *echitammonium hydroxide* are so strongly basic that they precipitate the hydroxides of copper, iron, aluminum, and lead, and decompose sodium and potassium chlorides, liberating the corresponding hydroxides. Hesse considers echitammonium the most strongly basic of all the alkaloids. Hesse also obtained by extraction with petroleum benzin *echicaoutchin, echiretin, echicerin, echitin,* and *echitein,* of which the three last mentioned are crystalline.

From *Alstonia constricta,* F. V. Müller and A. Rummel obtained *alstonine.* Oberlin and Schlagdenhauffen found in 1879 another alkaloid, *alstonicine.* Hesse (*Ann. Ch. Ph.,* 1880, ccv) subsequently analyzed the bark and found alstonine, the *chlorogenine* of a former investigation, which has the composition $C_{21}H_{20}O_4N_2$, *porphyrine,* $C_{21}H_{25}O_2N_3$, and *alstonidine.* The alkaloids and their salts in acidulated solutions show decided blue fluorescence.

Uses.—This drug has been used for many years in Australia and the Philippine Islands in the treatment of *malarial* and other *fevers,* as well as a simple bitter. The alkaloid ditaine has been scientifically studied by Harnach (*A. E. P. P.,* 1877, xvii, p. 126), who finds that it has a paralyzing effect upon the endings of the motor nerve similar to that produced by curara. In large dose it also paralyzes the cardio-inhibitory nerves and lowers blood pressure. There is nothing in this study, which is, as far as we know, the only scientific investigation of the drug which has been made, to explain any action in malaria. Nevertheless some of the clinical reports, especially from the eclectic physicians, have been extremely laudatory, vaunting it even as a substitute for quinine.

Dose, two to four grains (0.13–0.25 Gm.).

ALTHÆÆ FOLIA. N. F.

ALTHEA LEAVES Alth. Fol. [Marsh Mallow Leaves]

"Althea leaves consists of the dried leaves of *Althæa officinalis* Linné (Fam. *Malvaceæ*). Althea leaves contain not more than 5 per cent. of stems and fruits or other foreign organic matter." *N. F.*

" The dried leaves of the Althæa officinalis L. without the presence of more than 5 per cent. of stems or other foreign matter." *N. F.*

Feuilles de Guimauve, *Fr.;* Folia Altheæ, *P. G.*

Althæa officinalis is an herbaceous perennial, with a perpendicular branching root and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are alternate, ovate to slightly cordate, toothed, often 3-lobed and of velvety texture. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The calyx is surrounded by a six to nine cleft involucel. The corolla has five spreading, obcordate petals, of a pale rose color. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant is native to Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country, from New England to New York and westward to Michigan and Arkansas. It is largely cultivated in Europe for medicinal use, particularly in Germany, Holland, Belgium and France. These countries supply most of the drug used in the United States.

The roots should be collected in autumn from plants at least two years old. They are usually prepared for the market by removing the outer layers. The commercial drug sometimes consists of the unpeeled root, which is sliced transversely and diagonally.

Description and Physical Properties.—The *root,* which is recognized by the U. S. P., is described as follows:

" *Unground Althea.*—Slenderly tapering, when entire up to 30 cm. in length and 2 cm. in thickness, usually cut into small pieces, about 5 mm. in diameter; externally whitish, longitudinally furrowed, frequently spirally twisted and covered with somewhat loosened bast-fibers; fracture of bark fibrous, of wood short and granular; internally yellowish-white; bark 1 to 2 mm. thick, porous, due to mucilage cells, and separated from the slightly radiating wood by a distinct grayish cambium zone; odor slight; taste sweetish, mucilaginous.

" *Powdered Althea.*—Starch grains numerous, up to 0.03 mm. in diameter, usually with a long central cleft; groups of fibers with thick, more or less lignified walls; tracheæ with scalariform thickenings or with bordered pores; calcium oxalate crystals few, in rosette aggregates, 0.020 to 0.035 mm. in diameter.

" Add 1 Gm. of Althea to 10 cc. of cold water allow it to stand with occasional stirring during thirty minutes, and filter through purified cotton: a pale yellow-colored mucilage is obtained, which is neutral to litmus paper and is colored a deep yellow on the addition of a few drops of sodium hydroxide T.S. The mucilage does not have a sour or ammoniacal odor." *U. S.*

The drug contains on the average 37 per cent. of starch, 35 per cent. of mucilage, 11 per cent. of pectin, 11 per cent. of sugar, 1.25 per cent. of fat and up to 2 per cent. of asparagin.

The abundant mucilage is situated chiefly in special cells, and can be seen to be in layers when alcohol is added. Kraemer (*A. J. P.,* 1898, p. 285) proposed the use of an alcoholic solution of methylene blue for the differentiation of the mucilage. It, with starch and saccharine matter, is taken out by boiling water. The gum may be extracted, without the starch, by cold water and forms a ropy mucilage.

The principle discovered in the root by Bacon, by him called *althein,* has been ascertained to be *asparagin.* This substance belongs to the group of amides and hence has been called *asparamide.* When decomposed it breaks up into ammonia and *aspartic acid,* $C_4H_7NO_4$, and one molecule of the resulting ammonium aspartate corresponds with one molecule of asparamide and one of water. (*J. P. C.,* xix, 208.) Asparagin, being now recognized as a derivative of succinic acid, is called *amido-succinamide,* and the aspartic acid is called *amido-succinic* acid. It is found in various other plants besides the marshmallow, as in the shoots of asparagus, in vetches grown in the dark, in all the varieties of the potato, and in the roots of the comfrey and licorice plant. According to Pira, asparagin has acid properties. It has no therapeutic value. Betaine has been obtained from althea by Orlow. (*Ph. Z. R.,* 1898.)

The roots of other *Malvaceæ* are sometimes substituted for that of marshmallow, without disadvantage, as they possess similar properties. Among these are *Althæa rosea* Cav., or *hollyhock,* and *Malva Alcea* L. The dark purple flowers of a variety of *A. rosea* have been proposed as a test for acids and alkalies . A strong infusion of these flowers imparts to slips of white filtering paper a permanent purplish-blue color, which is reddened by acids, and rendered bluish-green by alkalies.

ALTHÆA OR MARSHMALLOW LEAVES, under the title of *Althææ Folia,* are official in the National Formulary. They are collected in June or July, while the plant is in flower, and dried. They are described in the N. F. as follows:

Description and Physical Properties.—"*Unground Althea Leaves.*—Crumpled or matted; gray-green or yellowish-gray-green; densely and finely tomentose throughout; petioles 1 to 6 cm. long; blades 3 to 15 cm. long and 3 to 10 cm. wide, thin, cordate or rhomboidal-ovate in outline, rounded or nearly truncate at the base, acute at the apex; margin doubly serrate-dentate, the principal teeth from 1 to 3 pairs, the lowest almost large enough to be regarded as lobes, the secondary very irregular, triangulate, acute, broader than long, the sinuses acute; 2 to 6 principal veins originating with the midrib in the petiole, prominent underneath, terete; branches of midrib arising at a wide angle, nearly straight, each terminating in a marginal tooth. Odor slight, scarcely characteristic; taste mucilaginous.

"*Powdered Althea Leaf.*—Grayish to grayish-green; numerous unicellular, non-lignified, stellate clustered hairs, up to 0.600 mm. long, usually in clusters of 2 to 6; few, short stalked, multicellular glandular hairs; calcium oxalate in rosette aggregates up to 0.030 mm. in diameter; epidermal tissue with stomata, the latter up to 0.037 mm. in length; few lamellated mucilage cells; pollen grains, few, spherical, spiny, up to 0.125 mm. in diameter." *N. F.*

Marshmallow leaves, like the root, are used for their mucilage which is, however, less abundant than in the root.

Uses.—The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. A syrup of althæa is official in the German Pharmacopœia, and was introduced into the U. S. Pharmacopœias of 1880 and 1890 (see *U. S. D.,* 18th edition, p. 1327). Owing to its tendency to ferment rapidly it was not retained in the U. S. P., but is found in the N. F. V. (See *Syrupus Althææ.*) The roots themselves, as well as the leaves and flowers, boiled and bruised, are sometimes employed as a poultice. Its most important use is as an excipient for pills. It enters, as an ingredient, into one mass and two pills of the U. S. P.

Dose of the leaves one-half to one drachm (2–4 Gm.).

Off. Prep.—From the root: Syrupus Althææ, *N. F.* From the leaves: Species Emollientes, *N. F.*

ALUMEN. U. S. (Br.)

ALUM

"Alum contains not less than 99.5 per cent. of $AlNH_4(SO_4)_2.12H_2O$ or $AlK(SO_4)_2.12H_2O$. The label of the container must indicate whether the salt is Ammonium Alum or Potassium Alum." *U. S.* "Purified Alum is aluminum and potassium sulphate (Potassium Alum), $Al_2(SO_4)_3,K_2SO_4,24H_2O$, or aluminum and ammonium sulphate (Ammonium Alum), $Al_2(SO_4)_3, (NH_4)_2SO_4,24H_2O$, and is obtained by the combination of aluminium sulphate with potassium sulphate or with ammonium sulphate." *Br.*

Alumen Purificatum, *Br.;* Aluminum and Potassium Sulphate, *U. S. P. VIII.;* Aluminii et Potassii Sulphas, *U. S.* 1870, Potassa Alum; Sulphas Aluminico-potassicus; Alun de potassium, *Fr. Cod.;* Alun, Sulfate d'Alumine et de Potasse, *Fr.;* Alumen ,*P. G.;* Alaun, Kalialaun, *G.;* Solfato di allumino e di potassio, Allume, *It.;* Sulfato aluminicopotasico, Alumbre, *Sp.*

Aluminii et Ammonii Sulphas; Sulphas Aluminico-Ammonicus; Alun ammoniacal, *Fr.;* Ammoniak-Alaun, *G.*

The name alum has been applied indifferently to two salts, one consisting of *aluminum trisulphate* combined with ammonium sulphate, the other of the same salt of aluminum combined with potassium sulphate, and distinguished as *ammonium alum* and *potassium alum.* From time to time one or the other of these has been given the official preference but at present both are recognized under the common title *Alumen* in the United States and British Pharmacopœias.

The British authority (1914) added the word "Purificatum" to the title.

AMMONIUM ALUM. *Aluminum and Ammonium Sulphate.*—It is made by adding ammonium sulphate to the solution of aluminum sulphate. This kind of alum formerly came into very general use, owing to the comparative cheapness of ammonia, and during the World War, owing to the great advance in the cost of potassium salt, was almost exclusively used. *Scotch alum,* made near Paisley, generally contains both potassium and ammonium. Ammonium alum resembles potassium alum so exactly that it cannot be distinguished by simple inspection; and in composition it is perfectly analogous to the potassium salt. It may be distinguished by subjecting it to a strong calcining heat, after which alumina will be the sole residue; or by rubbing it with potassium hydroxide or lime and a little water, when the odor of ammonia will be perceived.

POTASSIUM ALUM. *Aluminum and Potassium Sulphate.*—Potassium alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, from the fact of their containing most or all of its constituents, are called *alum* *ores.* The principal alum ores are the *alum stone,* or *alunite,* which is a native mixture of aluminum sulphate and potassium sulphate, found in large quantities at Tolfa and Piombino in Italy; certain natural mixtures of iron disulphide with alumina, silica, and bituminous matter, called *aluminous schist* or *alum slate; bauxite,* a native aluminum hydroxide, and *cryolite.* (See *Sodii Carbonas.*)

At the Solfatara, and other places in Southern Italy, alum was formerly extracted from earths containing it ready formed. The ground being of volcanic origin, and having a temperature of about 40° C., an efflorescence of pure alum formed upon its surface. This was collected and lixiviated, and the solution crystallized by slow evaporation in leaden vessels sunk in the ground. The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months, the mineral being frequently sprinkled with water, in order that it may be brought to a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum united with a certain quantity of aluminum hydroxide. The latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this kind of ore.

Large amounts of alum are made from *alum shale,* a clay containing iron pyrites. On calcination the sulphur of the pyrites is in part converted into sulphuric acid, which unites with the alumina. The iron, in the meantime, is almost wholly converted into sesquioxide, and thus becomes insoluble. The matter is lixiviated, the solution concentrated and potassium chloride added and the resultant alum crystallized out. When alum slate is easily disintegrated, it is not calcined, but merely placed in heaps and occasionally sprinkled with water. The iron disulphide gradually absorbs oxygen, and passes into ferrous sulphate, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina, so that, after the chemical changes are completed, the heap contains both ferrous sulphate and aluminum sulphate. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates produced is concentrated to the proper degree in leaden boilers. The ferrous sulphate crystallizes, while the aluminum sulphate, being of a more soluble nature, remains in the mother waters.

For an account of the manufacture of alum in India, see *C. D.,* 1892, 636. *Bauxite,* a hydrated oxide of aluminum, containing from 56 to 60 per cent. of aluminum oxide, has within recent years become one of the most important raw materials for the alum manufacture. It is found in very rich deposits in Georgia and Alabama. *Cryolite,* a double fluoride of sodium and aluminum, also serves as a source of supply, the aluminum hydroxide being produced as an intermediate product.

The elements *rubidium* and *cæsium* are found in *lepidolite,* and, as much of the alum in continental Europe is made from this mineral, Salzer found samples of commercial potassium alum which contained a considerable quantity of rubidium alum; this contaminated potassium alum is less soluble in water than ordinary alum. (*A. Pharm.,* 1887, p. 217.)

Description and Physical Properties.—"Large, colorless crystals, crystalline fragments, or a white powder. Alum is odorless, and has a sweetish, strongly astringent taste. One Gm. of Ammonium Alum is soluble in 5.2 cc. of water at 25° C., and in 0.3 cc. of boiling water. One Gm. of Potassium Alum is soluble in 7.2 cc. of water at 25° C., and in 0.3 cc. of boiling water. Alum is insoluble in alcohol but is freely soluble in glycerin. When heated, Alum fuses, and at about 200° C. loses all of its water of crystallization. When strongly heated, it loses sulphuric anhydride, becoming incompletely soluble in water.

"Sodium hydroxide T.S. added to an aqueous solution of Ammonium Alum (1 in 20) at first causes a precipitate which completely dissolves in an excess of the reagent, ammonia being evolved. Potassium Alum imparts a violet color to a non-luminous flame. The addition of 10 cc. of sodium bitartrate T.S. to 5 cc. of a saturated aqueous solution of Potassium Alum produces within thirty minutes a white, crystalline precipitate. Sodium hydroxide T.S. added to an aqueous solution of Potassium Alum (1 in 20) at first causes a precipitate, which completely dissolves in an excess of the reagent, but no ammonia is evolved. Unless otherwise indicated Ammonium Alum and Potassium Alum conform to the following tests: An aqueous solution of Alum (1 in 20) is acid to litmus paper. An aqueous solution of Alum (1 in 20) responds to the reactions for aluminum, and for sulphates.

"An aqueous solution of Alum meets the requirements of the test for *heavy metals.* An aqueous solution of Alum meets the requirements of the test for *arsenic.* Add 5 drops of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of Alum (1 in 150): no blue color is produced immediately (*iron*). Completely precipitate the aluminum from a boiling solution of 1 Gm. of Ammonium Alum in 100 cc. of distilled water by the addition of a slight excess of ammonia water, and filter: not more than 0.5 per cent. of residue remains on evaporating the filtrate to dryness and igniting (*alkali and earths*).

"**Assay.**—Dissolve about 1 Gm. of Alum, accurately weighed, and about 1 Gm. of ammonium chloride in 250 cc. of distilled water. Heat the solution to boiling, and add a slight excess of ammonia T.S. to precipitate aluminum hydroxide. Collect the precipitate on a filter, wash thoroughly with hot distilled water, dry, ignite strongly, and weigh. The weight of the aluminum oxide so obtained, multiplied by 8.889 indicates its equivalent in $AlNH_4(SO_4)_2.12H_2O$ and when multiplied by 9.302 indicates its equivalent in $AlK(SO_4)_2.12H_2O$. Each Gm. of aluminum oxide corresponds to 8.874 Gm. of $AlNH_4(SO_4)_2.12H_2O$ and to 9.286 Gm. of $AlK(SO_4)_2.12H_2O$." *U. S.*

"In colorless transparent crystalline masses; taste sweetish, astringent. Soluble in 10 parts of *water,* the solution being clear and having an acid reaction; freely soluble in *glycerin,* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of aluminium, of potassium or ammonium, and of sulphates. Yields no characteristic *reactions* for copper, lead, zinc, calcium, or sodium, and not more than very slight *reactions* for iron. *Arsenic limit* 5 parts per million." *Br.*

Its sp. gr. is 1.71. It reddens litmus, but changes the blue tinctures of the petals of plants to green. When heated a little above 100° C., it undergoes the aqueous fusion; and, if the heat be continued, it loses its water, swells up, becomes a white, opaque, porous mass, and is converted into the official *exsiccated alum.* (See *Alumen Exsiccatum.*) Exposed to a red heat, it gives off oxygen, together with sulphurous and sulphuric oxides, and the residue consists of aluminum oxide and potassium sulphate. When calcined with finely divided charcoal, it forms a spontaneously inflammable substance, called *Homberg's pyrophorus,* which consists of a mixture of potassium sulphide, alumina, and charcoal.

Several varieties of alum are known in commerce. *Roche alum,* so called from its having come originally from Rocca, in Syria, is a sort which occurs in fragments about the size of an almond, and of a pale rose color, which is given to it, according to Pereira, by bole or rose-pink. *Roman alum,* which is another variety found in commerce, also occurs in small fragments, covered with a reddish-brown powder, resembling ochre, which is put on by the manufacturers. It has been supposed that the powder contains iron, but this is probably a mistake. Roman alum crystallizes in cubes, from the fact that the crystals are deposited from a solution always containing an excess of alumina, which decomposes any iron salt that may be present. This crystalline form of alum is, therefore, an index of its freedom from much contamination with iron.

All the alums of commerce contain more or less ferrous sulphate, varying from five to seven parts in the thousand. The iron is readily detected by adding to a solution of the suspected alum a few drops of potassium ferrocyanide, which will cause a greenish-blue tint, if iron be present. It may be detected also by precipitating the alumina as a subsulphate with a solution of potassium hydroxide, and afterwards adding the alkali in excess. This will redissolve the precipitate, with the exception of any iron, which will be left in the state of sesquioxide. The proportion of iron usually present, though small, is injurious when the salt is used in dyeing. Alum may, however, be purified, either by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools, or by repeated solution and crystallization.

ALUMINUM.—The existence of the metal aluminum (formerly known as *aluminium*) was rendered probable by Sir H. Davy in 1808; but it was not fairly obtained until 1828, when Wöhler procured it in an impure state, in globules of the size of a pin's head, by the action of potassium on aluminum chloride. In 1854, Deville succeeded in obtaining the pure metal in ingots by decomposing the same chloride with sodium. The process of Deville remained the only practical process for its manufacture until 1886, when the Messrs. Cowles of Cleveland, Ohio, succeeded in effecting the reduction of corundum, the native oxide, by charcoal with the aid of a powerful electric current from a Brush dynamo-electric machine, using large carbon electrodes. They manufactured the pure aluminum and the alloys of copper known as aluminum bronzes. This process in turn has been practically displaced by the Hall process, as operated by the Pittsburg Reduction Company at Niagara Falls and elsewhere. This is to electrolyze pure *alumina* (*aluminum trioxide*) dissolved in a bath of melted cryolite. The cryolite (a double fluoride of sodium and aluminum) is continuously regenerated, so that by feeding in the pure alumina the process can be made continuous. A German process, that of Graetzel, for electrolyzing the fused chloride, is also in successful use.

Aluminum is silver-white, sonorous, unalterable in the air, and lighter than glass, having the low sp. gr. of 2.56. Its fusing point is somewhat lower than that of silver. It is not attacked by sulphuric or nitric acid, nor tarnished by hydrogen sulphide. It is acted upon slightly by acetic acid and is attacked readily by alkaline solutions. Its best solvent is hydrochloric acid. After silver, gold, and platinum, it is the least alterable of the metals.

Uses.—Alum is absorbed from the intestinal tract only in relatively small quantities, although Gies (*J. A. M. A.*, 1911, lvii, p. 57) has shown that the former view that it was completely excreted, unabsorbed, with the feces is incorrect. The germicidal power of alum is lower than many of the other salts of aluminum. According to Miquel it will inhibit the multiplication of bacteria in the proportion of about one part in two hundred.

Alum is a powerful astringent with very decided irritant qualities, and when taken internally in sufficient quantities is emetic and purgative, and may even cause gastro-intestinal inflammation. It is widely employed in various conditions in which an astringent or styptic is desired, as for instance, *serous diarrheas,* *pharyngitis,* local *hemorrhages,* and the like. It has also been used internally in the treatment of *colica pictonum* in which disease it seems to do more than act as a chemical precipitant of any lead in the intestinal tract and to exercise some beneficial action upon the intestines directly. As an emetic it was formerly used to a considerable extent in the treatment of *laryngeal diphtheria,* but has in modern times been largely replaced by various operative procedures. It is occasionally employed to empty the stomach in cases of poisoning, but is inferior for this purpose to zinc sulphate. As a gargle in various *anginas* it has been a favorite remedy, but because of its acidity exercises a destructive influence upon the teeth and is inferior to aluminum acetate.

The most important use of alum to-day is as a local styptic in external *hemorrhages,* in *epistaxis,* and other bleeding from mucous membranes to which it can be directly applied. It is also employed as an astringent in *leucorrhea,* unhealthy *ulcers,* and similar conditions. As an astringent it is usually employed in strengths ranging from 1 to 5 per cent., according to the location to which it is applied. Occasionally powdered alum may be thinly dusted over the area. As a styptic if the bleeding point is easily accessible it may be touched with the alum stick or the powdered alum directly applied. In *epistaxis* it is usually employed by plugging the nares with pledgets of cotton soaked in a saturated solution. When used as an astringent on the more delicate mucous membranes, as in *conjunctivitis,* it is often desirable to modify its action by combining it with albuminous matter as in the form of the *alum curd.* This is made by boiling two drachms of alum in a pint of milk and straining off the whey.

When taken in large dose alum acts as an irritant poison causing burning in the mouth and throat followed by vomiting, purging, collapse, and other symptoms of toxic gastroenteritis. Ricquet records a fatal case from an ounce of alum. (*J. P. C.,* Oct., 1873, p. 333.) When small quantities of the soluble salts of aluminum are introduced into the circulation they produce a slow form of poisoning characterized by motor palsies and areas of local anesthesia with fatty degeneration in the kidney and liver. The nervous symptoms have been shown by Doellken (*A. E. P. P.,* 1897, xl) to be due to anatomical changes in the nerve centers. There are also often symptoms of gastro-intestinal inflammation which is presumably the result of the effort of the glands of the intestinal tract to eliminate the poisoning.

The question of the toxic effects of repeated small doses of alum has become a matter of some importance because of the widespread use of the salt in baking powder. It has been held by some that under these conditions the aluminum is converted into a form which is non-absorbable and therefore harmless. The experiments of Gies appear to demonstrate that bread stuffs made from alum baking powder yield their alum to absorption, at least partially. The wider question of whether the relatively minute doses of aluminum which enter the system under these conditions is deleterious or not, is still a matter of dispute.

Alum is incompatible with the alkali hydroxides, carbonates and bicarbonate, potassium bitartrate and lead acetate.

Dose, as an astringent, five to twenty grains (0.32–1.3 Gm.); as an emetic, one drachm (3.9 Gm.).

Off. Prep.—Alumen Exsiccatum, *U. S.;* Glycerinum Aluminis, *Br.;* Alumen Exsiccatum, *Br.*

ALUMEN EXSICCATUM. U. S., Br.

EXSICCATED ALUM Alum. Exsic. [Dried Alum, Burnt Alum]

"Exsiccated Alum, when recently dried to constant weight at 200° C., contains not less than 96.5 per cent. of anhydrous $AlNH_4(SO_4)_2$ or of anhydrous $AlK(SO_4)_2$. The label of the container indicating whether it is made from Ammonium Alum or from Potassium Alum." *U. S.*

Alun calciné, desséché, brûlé, *Fr.;* **Alumen ustum,** *P. G.;* **Gebrannter Alaun, Gebrannter Kalialaun,** *G.;* **Solfato di allumino e di potassio usto, Allume usto,** *It.;* **Solfato aluminico-potasico anhidro, Alumbre calcinado,** *Sp.*

"Alum, in small pieces, 100 Gm. To make about 55 Gm. Place a thin layer of alum in a tared, shallow, porcelain dish, and heat it cautiously on a sand bath until liquefied. Continue the application of heat, at a temperature not exceeding 200° C. and stir constantly, until aqueous vapors cease to evolve and a dry, white, porous mass is obtained. When cold, reduce the product to a fine powder." *U. S.*

"Potassium Alum, 100 grammes. Heat the Potassium Alum in a porcelain dish or other suitable vessel till it liquefies, then increase and continue the application of heat until aqueous vapor ceases to be disengaged, and the salt has lost from 45 to 46 per cent. of its weight." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet if the heat be too great the salt itself is decomposed, and the desired end is not obtained. If the alum employed be the potassium alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonium salt. To guard against failure from this cause, the Pharmacopœias formerly directed 205° C. as the highest heat to be used, and the checking of the operation when nearly all the water has been driven off, as indicated by the weight of the residue. John M. Maisch satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough, and the direction of the Pharmacopœias, as to the weight of the residue, insures that a sufficient heat will be employed. By the official process there is left behind about one and one-fourth per cent. of the water of crystallization, when potassium alum is used.

Description and Physical Properties.—"A white, odorless powder. It has a sweetish astringent taste, and absorbs moisture on exposure to air. One Gm. of Exsiccated Alum is very slowly and usually incompletely soluble in about 20 cc. of water at 25° C. One Gm. is soluble in about 1.5 cc. of boiling water. It is insoluble in alcohol. Exsiccated Alum responds to the reactions, respectively, for Ammonium Alum or Potassium Alum described under *Alumen.*

"Add 2 Gm. of Exsiccated Alum to 40 cc. of distilled water, and allow it to stand with occasional agitation for twenty-four hours. Collect the insoluble residue on previously dried, counterbalanced filter papers, or a Gooch crucible, wash with 50 cc. of distilled water, and finally dry to constant weight at 100° C.: the residue weighs not more than 0.05 Gm. Dry about 1 Gm. of Exsiccated Alum to constant weight at 200° C. in an air bath: the loss does not exceed 10 per cent. An aqueous solution of Exsiccated Alum meets the requirements for *arsenic, heavy metals, iron,* and Exsiccated Ammonium Alum meets the test for limit of *alkali and earths,* under *Alumen,* allowance being made for the difference in strength.

"**Assay.**—Dry about 0.5 Gm. of Exsiccated Alum to constant weight at 200° C., weigh accurately, and dissolve in 100 cc. of distilled water. Filter, if necessary, thoroughly wash the insoluble residue with distilled water, dilute the filtrate and washings to about 250 cc. with distilled water, and add 1 Gm. of ammonium chloride. Proceed with the assay as directed under *Alumen,* beginning with the words 'Heat the solution,' second line of the assay. The weight of the aluminum oxide so obtained multiplied by 4.650 indicates its equivalent in $AlNH_4(SO_4)_2$, and multiplied by 5.063 indicates its equivalent in $AlK(SO_4)_2$. Each Gm. of aluminum oxide corresponds to 4.643 Gm. of $AlNH_4(SO_4)_2$ and to 5.055 Gm. of $AlK(SO_4)_2$.

"Preserve in well-closed containers and do not dispense if it contains more than 10 per cent. of moisture." *U. S.*

"A white powder slowly and completely soluble in 20 parts of *water.* Absorbs moisture on exposure to air. Yields the reactions and is free from the impurities indicated under 'Alumen Purificatum." *Br.*

Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses 45 per cent. of its weight in dissipated water. Exsiccated alum resists the action of cold water for a long time, showing its altered aggregation. In composition it differs from crystallized alum merely in the absence of water.

Uses.—Exsiccated alum has the same medicinal properties as ordinary alum, but it is much more powerful and irritant and must be employed in correspondingly dilute solutions. It is used as a mild escharotic to destroy *exuberant granulations,* on which it may be freely dusted.

ALUMINI CHLORIDUM. N. F.

ALUMINUM CHLORIDE Alum. Chlor.

"Aluminum Chloride contains $AlCl_3.6H_2O$ (241.58) corresponding to not less than 20.5 per cent. of aluminum oxide (Al_2O_3)." *N. F.*

Description and Physical Properties.—"Aluminum Chloride occurs as a white, or yellowish-white deliquescent, crystalline powder; nearly odorless; taste sweetish and very astringent. One Gm. dissolves in about 0.5 cc. of water and in about 4 cc. of alcohol at 25° C., also soluble in glycerin.

"An aqueous solution of the salt (1 in 10) is clear and is acid to litmus. Separate portions of an aqueous solution of the salt (1 in 10) yield with silver nitrate T.S. a white curdy precipitate insoluble in nitric acid, with ammonia water a white gelatinous precipitate almost insoluble in an excess of ammonia water, and with sodium hydroxide T.S. a white gelatinous precipitate completely soluble in an excess of the reagent.

"Ten cc. of an aqueous solution of the salt (1 in 100) after the addition of 0.2 cc. of barium chloride T.S. does not become cloudy within one minute (*sulphate*). The addition of 0.3 cc. of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 150) does not produce a blue coloration within one minute (*iron*). An aqueous solution of the salt does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 0.5 Gm. of the salt, previously dried over sulphuric acid and accurately weighed, in 100 cc. of distilled water, add 1 Gm. of ammonium chloride, boil and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 20.5 per cent. of the weight of the Aluminum Chloride taken for the assay.

"Preserve it in well-closed containers." *N. F.*

Uses.—Externally it is used as an astringent and antiseptic, especially in *hyperidrosis.* It is an ingredient in some of the proprietary preparations for diminishing the odor of perspiration; some of these solutions containing over 30 per cent. of aluminum chloride. Internally it has been employed in *locomotor ataxia* in *doses* of five grains (0.3 Gm.).

Off. Prep.—Liquor Hydrastini Compositus, *N. F.*

ALUMINI SULPHAS. N. F.

ALUMINUM SULPHATE Alum. Sulph.

"Aluminum sulphate contains not less than 99.5 per cent. of $Al_2(SO_4)_3.18H_2O$ (666.47)." *N. F.*

Concentrated Alum; Sulfas Aluminicus; Sulphate d'Aluminium, *Fr.;* Aluminium Sulfuricum, *P. G.;* Schwefelsaüre Thonerde, *G.*

This salt may be manufactured by various methods (see U. S. D., 19th ed., p. 124), but is now obtained chiefly as one of the by-products in the manufacture of soda from cryolite or from bauxite.

Description and Physical Properties.—"Aluminum Sulphate occurs as a white crystalline powder, shining plates, or crystalline fragments; without odor, having a sweetish and afterwards an astringent taste; permanent in the air. One Gm. dissolves in 1 cc. of water at 25° C.; it is more soluble in boiling water, but insoluble in alcohol.

"When gradually heated to about 200° C., it loses its water of crystallization (about 48.6 per cent. of its weight). An aqueous solution of the salt (1 in 20) is acid to litmus. Separate portions of an aqueous solution of the salt (1 in 20) yield with barium chloride T.S. a white precipitate insoluble in hydrochloric acid, and with sodium hydroxide T.S. a white gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride T.S.

"Gently heat 1 Gm. of Aluminum Sulphate with 10 cc. of sodium hydroxide T.S.; the liquid does not evolve the odor of ammonia. A filtered aqueous solution of the salt (1 in 10) does not become more than faintly opalescent within five minutes after the addition of an equal volume of tenth-normal sodium thiosulphate (*free acid*). The addition of 5 drops of potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 150) does not produce at once a blue coloration (*iron*). An aqueous solution of the salt does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 0.5 Gm. of Aluminum Sulphate, accurately weighed, in 100 cc. of distilled water, add 1 Gm. of ammonium chloride, boil and then precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it with distilled water, dry, ignite thoroughly and weigh. The weight of the aluminum oxide so obtained is not less than 15.23 per cent. of the weight of the Aluminum Sulphate taken for the assay, corresponding to not less than 99.5 per cent. of $Al_2(SO_4)_3.18H_2O$." *N. F.*

Uses.—Aluminum sulphate has medicinal properties very similar to those of alum. It has been employed in aqueous solution (20 grains in a fluidounce or stronger) as an antiseptic, detergent application to *foul ulcers,* and as an injection in *fetid discharges from the vagina.* Solution of aluminum sulphate is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by Mentel as a hemostatic, under the name of *benzoinated solution of alumina.* It resembles the *styptic liquid of Pagliari.* It is prepared by saturating with gelatinous alumina a solution made of eight ounces of aluminum sulphate dissolved in a pint of water. To the saturated solution six drachms of bruised benzoin are added, and the whole is kept at a temperature of about 65.5° C. for six hours, with occasional agitation, so that the liquid, after filtration, may have about the density 1.26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzoinated solution, remarkable for its very sweet odor and astringent balsamic taste. Benzoinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in *leucorrhea.*

Off. Prep.—Liquor Alumini Acetatis, *N. F.;* Liquor Alumini Subacetatis, *N. F.*

AMIDOPYRINA. U. S.

AMIDOPYRINE Amidopyrin.

"Dimethylamino-antipyrine $[C_3ON_3(CH_3)_4.C_6H_5]$." U. S.

Pyramidonum, *Fr. Cod.;* Pyramidon, *P. G.;* Dimethylamino Antipyrinum.

This compound may be regarded as a derivative of antipyrine in which an hydrogen atom of the pyrazolon group is replaced by $N(CH_3)_2$. It is manufactured by the reduction of isonitroso-antipyrine with zinc and subsequent methylation by means of methyl iodide.

It occurs as a colorless crystalline powder, practically tasteless, and moderately soluble in water. From antipyrine it may be distinguished by the facts that it gives a fugitive violet color with ferric chloride instead of red; with nitrous acid it gives a temporary purplish instead of a more permanent green reaction; with nitric acid it yields an amethyst instead of a yellow color.

Description and Physical Properties.—"Colorless or white, small crystals, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Amidopyrine is soluble in 18 cc. of water, 1.5 cc. of alcohol, 12 cc. of benzene, 1 cc. of chloroform, and in 13 cc. of ether, at 25° C.

"Amidopyrine melts between 107° and 109° C. An aqueous solution of Amidopyrine (1 in 25) is slightly alkaline to litmus paper. To 5 cc. of an aqueous solution of Amidopyrine (1 in 25) add 3 drops of diluted hydrochloric acid and 1 cc. of ferric chloride T.S.: a bluish-violet color is produced. On the subsequent addition of a few cc. of diluted sulphuric acid, the color changes to violet-red. The addition of 5 drops of silver nitrate T.S. to 5 cc. of an aqueous solution of Amidopyrine (1 in 25) produces an intensely violet color (other oxidizing substances yield the same color). On allowing the mixture to stand, a grayish-black precipitate of metallic silver is deposited. To a solution of about 0.02 Gm. of Amidopyrine in 5 cc. of distilled water, add 2 drops of sulphuric acid and 2 drops of a 10 per cent. solution of sodium nitrite: a transient blue color is produced which disappears quickly, the liquid remaining colorless (the appearance of a green color indicates *antipyrine*). An aqueous solution of Amidopyrine (1 in 25) added to a freshly prepared solution of potassium ferricyanide, containing a little ferric chloride, produces at once a dark blue color or precipitate (difference from *antipyrine*).

"Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of Amidopyrine in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Its aqueous solution (1 in 25) meets the requirements of the test for *heavy metals*. The addition of a few drops of silver nitrate T.S. to 5 cc. of an aqueous solution of Amidopyrine (1 in 25), previously acidulated with a few drops of diluted nitric acid, produces no turbidity at once (*chloride*)." *U. S.*

Uses.—Amidopyrine resembles antipyrine in its general effects upon the system. It is, however, somewhat slower and more persistent in its action and is also asserted to be more powerful in its analgesic properties. Although the details of its fate in the body are not definitely understood, it is eliminated in the urine in part as a compound which yields an amethyst color with ferric chloride and is probably antipyrylurea. At times, after its administration, the urine acquires a pinkish hue which was at one time attributed to the formation of hematoporphyrin, but is probably due to decomposition products of the drug itself, perhaps rubaronic acid. It is also asserted that it increases the nitrogenous metabolism and must, therefore, be used with much caution in diabetic patients.

While unquestionably it is capable of reducing the body temperature in various *fevers*, its use as an antipyretic is probably open to the same objections as other drugs of this class. Its most important field of usefulness is for the purpose of relieving *pain* in *migraine, neuralgia, dysmenorrhea, locomotor ataxia*, and similar conditions. Like antipyrine it very greatly enhances the anodyne properties of the opiates, even in those forms of pain in which it is not highly efficacious by itself. Bardet (*B. G. T.*, March 30th, 1903) has found it useful in the treatment of *asthma*.

Dose, from two to eight grains (0.12–0.5 Gm.).

AMMONIA

AMMONIA

All the compounds of ammonium owe their distinctive properties to the presence of a gas, composed of nitrogen and hydrogen (NH_3) called *ammonia*. This is easily obtained by the action of lime on ammonium chloride,—when the calcium unites with the hydrochloric acid, so as to form calcium chloride and water, and the ammonia is liberated. It is transparent and colorless, but possesses an acrid taste and an exceedingly pungent odor. It has a powerful alkaline reaction, and, from this property and its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0.56 compared with air. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. The sources of ammonia will be mentioned elsewhere (see *Ammonii Chloridum*), but a synthesis of ammonia from simple elements may be noted here. Hydrogen, nitrogen, and aqueous vapor in the presence of porous contact substances like pumice, charcoal, etc., unite to form ammonia, and this, in the presence of CO and CO_2, gives rise to ammonium formate or carbonate. These elements in the presence of moisture, as in damp atmosphere, under the influence of an electric discharge, produce ammonium nitrate directly as follows: $N_2 + O + 2H_2O = NO_3NH_4$. (See also nitrogen fixation under *Acidum Nitricum.*)

As the gas ammonia exists in the free state, the molecule NH_3 is a definite saturated compound under ordinary conditions. When, however, ammonia gas is mixed with hydrochloric acid gas or its aqueous solution with hydrochloric acid in solution, the two unite to form a new compound, NH_4Cl, which proves to be a definite compound, analogous to potassium or sodium chlorides. Berzelius, therefore, proposed to call this ammonium chloride, assuming that the monad group (NH_4) acted like the monad metal K in forming compounds, and in fact it is found that when sulphuric, nitric, carbonic, and other acids are neutralized by *ammonia* gas or solution, crystallizable salts like $(NH_4)_2SO_4$, NH_4NO_3, and $(NH_4)_2CO_3$ are formed, which are termed ammonium sulphate, nitrate, and carbonate respectively. *Ammonium* is believed to exist, although it has not been isolated in a pure state. *Ammonium amalgam* is a compound of ammonium with mercury.

Ozone oxidizes the elements of ammonia, producing water and nitric acid; the latter, uniting with undecomposed ammonia, generates ammonium nitrate. Ordinary oxygen, under the influence of platinum-black, or finely-divided copper, likewise oxidizes the elements of ammonia, the nitrogen to the extent only of forming nitrous acid, with the result of producing ammonium nitrite.

AMMONIACUM. Br.

AMMONIACUM

"Ammoniacum is a gum-resin exuded from the flowering and fruiting stem of Dorema Ammoniacum, *D. Don,* and possibly other species of Dorema." *Br.*

Gum Ammoniac, Gummi-resina Ammoniacum; Ammoniaque, Gomme-résine ammoniaque, Gomme ammoniaque, *Fr.;* Ammoniacum, *P. G.;* Ammoniak, Ammoniak-gummi, *G.;* Gomma ammoniaco, *It.;* Gomo-resina amoniaco, Goma amoniaco, *Sp.;* Ushek, *Ar.;* Semugh belsheren, *Pers.*

This gum-resin was dropped in the Eighth Revision of the U. S. Pharmacopœia on account of its having fallen, at least in America, almost into desuetude. It is, however, official in the British as well as the Swiss and German Pharmacopœias.

The ammoniac plant (*Dorema Ammoniacum*) is an erect, fleshy stemmed, perennial herb with a stem having a few pinnately decompound leaves near the base and bracts above, and woolly umbels of small white flowers; grows spontaneously in Farsistan, Irak, Khorassan, and other Persian provinces extending into Southern Siberia. It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers, it appears that in the month of May the plant is pierced in innumerable places by beetles. A milky juice contained within reservoirs of the cortex is thus induced to exude. Part of this juice, exuding through the punctures, concretes upon the stem, a part falls to the ground and becomes mixed with impurities and when quite dry is collected by the natives. Fontanier states that the juice exudes spontaneously, and that the harvest is about the middle of June. The gum-resin occurs in special reservoirs near the phloem tissues of the stems, roots, and petioles of the leaves. According to Grant, the drug is collected in Sygham, like asafetida, from the root of the plant. The gum-resin is sent to Bushire, whence it is transmitted to India, chiefly to Bombay. A small portion is said to be taken to the ports of the Levant, and thence distributed. The name of the drug is thought to have been derived from the temple of Jupiter Ammon in the Libyan desert, where the ammoniac of the ancients is said to have been collected; but Don considers it a corruption of *Armeniacum,* originating in the circumstance that the gum-resin was formerly imported into Europe through Armenia. The drug is now collected mainly in the central provinces of Persia and exported from Persian Gulf ports.

The *African Ammoniac* is said by Holmes (*P. J.,* 1907, lxxix, p. 570) to be derived from the *Ferula communis* L., var. *brevifolia.* It has been described by Daniel Hanbury as follows: "In large, compact, dark, heavy masses, formed of agglutinated tears of a gum-resin of hard, waxy consistence. The tears are opaque, white or of a pale greenish-yellow, mixed with others of a blackish-brown, which, with vegetable and earthy impurities, constitute a large portion of the mass." The odor of the drug is feeble, and quite different from that of the Persian gum-resin; its taste slightly acrid and very persistent. Examined by John Moss, it was found to consist of 67.76 per cent. of resin, 9.1 of gum, 4.29 of water and volatile oil, and 18.85 of bassorin and insoluble matters. (*P. J.,* 1873, p. 742.) It is used chiefly for incense in Mohammedan countries, and is sent eastward by the caravans, or in vessels from the ports of Morocco to Alexandria.

Properties.—Ammoniac comes either in the state of tears, or in aggregated masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out and kept for use. These are of an irregular shape, usually more or less globular, from 5 to 25 mm. in diameter, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal, shining, waxy fracture. The masses are often of a darker color and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty-gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand or earth. According to the 1890 U. S. Pharmacopœia, only such masses should be considered up to the standard as are composed entirely of tears "without any intervening dark-colored substance."

The odor of ammoniac is peculiar, and stronger in the mass than in the tears The taste is slightly sweetish, bitter, and somewhat acrid. The sp. gr. is 1.207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odor. It is partly soluble in water, alcohol, ether, acetic acid, and alkaline solutions. The alcoholic solution is transparent, but is rendered milky by the addition of water.

"In small dull white, yellowish-white, or brownish-white tears or in nodular masses varying from about five to twenty-five millimetres in diameter. Hard and brittle when cold, the freshly fractured surface having a waxy lustre; softens when warmed. Internally opaque and varying in color from milky-white to pale brownish-yellow. Faint characteristic but not alliaceous odor; taste bitter, acrid. Triturated with *water* forms a white emulsion. Freshly fractured surface colored yellow by *solution of sodium hydroxide* and dark-red or orange by *solution of chlorinated soda.* The solution obtained by boiling 1 gramme of the powdered gum-resin with 10 millilitres of *water,* filtering, and adding *alcohol* (90 per cent.) till clear, assumes a reddish-violet coloration on the addition of one drop of *T. Sol. of ferric chloride.*

The solution obtained by boiling 1 gramme of the coarsely powdered gum-resin for a few minutes with 10 millilitres of *hydrochloric acid* diluted with an equal volume of *water* does not exhibit a blue fluorescence when filtered and made alkaline with *solution of ammonia* (absence of asafetida and African ammoniacum). Ash not more than 7 per cent." *Br.*

For list of its physical constants see Dieterich. (*Ph. Ztg.*, xcvi, 401, and *P. J.*, 1900, 647.)

Tschirch and Luz (*A. Pharm.*, 1895, p. 571) have made an elaborate research of the chemistry of ammoniac, and state the following conclusions. Ammoniac contains resin, gum, and volatile oil, together with about 3.5 per cent. of a residue insoluble in water and alcohol. The portion soluble in alcohol and ether is a mixture of a so-called acid resin and a neutral resin, and amounts to 69 per cent. Both resins are free from sulphur, despite the statement of Preiszewski, who considered the latter of them to contain sulphur. The saponification of the so-called acid resin yielded salicylic acid of the formulas $C_6H_4OHCOOH$ and $C_6H_4OHCOOH + \frac{1}{2}H_2O$. Along with this were volatile acids, consisting of valeric and butyric acids, and an alcohol which belongs to the class of *resinotannols,* and has the same formula as galbaresinotannol, $C_{18}H_{30}O_3$. The resin is, therefore, a salicylic ester of resinotannol. From this resinotannol both the acetyl and the benzoyl derivatives were made, and the formula $C_{18}H_{30}O_3$ thus established. On oxidizing the resinotannol with nitric acid, *styphnic acid* was obtained, and on fusing it with potassium hydroxide, resorcinol was yielded. Volatile oil was found in small amount only. It contains no umbelliferone, and is free from sulphur. The crude ammoniac showed traces of a free acid which was recognized as salicylic both by its fusing point and the ferric chloride reaction. The gum contained 3.5 per cent. of ash, of which 1.2 per cent. was calcium oxide, so that the gum is probably related to gum arabic, and is an acid calcium arabinate.

Plugge's analysis (*A. Pharm.*, 1883) gave 1.27 per cent. of volatile oil, 65.53 per cent. of resin, and 26.10 of gum. Semmler and Roenish (*J. Chem. S.*, 1918, cxiv, p. 118) obtained 0.3 per cent. of volatile oil containing linalyl acetate, citronellyl acetate, ferulene doremone, a ketone and cetyl alcohol, which has not hitherto been reported in plants. This oil has a disagreeable odor. It contains no sulphur nor umbelliferone.

Uses.—This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates, but is now seldom administered. The complaints in which it was most frequently used were *chronic catarrh, asthma,* and other *pectoral affections* attended with deficient expectoration without acute inflammation, or with a too copious secretion from the bronchial mucous membrane, dependent upon debility of the vessels. It is usually administered in combination with other expectorants, with tonics, or with emmenagogues. Externally applied, in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints, and other indolent tumors. (See *Emplastrum Ammoniaci cum Hydrargyri, U. S. Dispensatory,* 19th edition, p. 437.) It is given in substance, in pill or emulsion. The latter form, however, is preferable. (See *Mistura Ammoniaci,* Br., 1914.)

Dose, from five to twenty grains (0.3–1.3 Gm.).

Off. Prep.—Mistura Ammoniaci, *Br.;* Pilula Ipecacuanhæ cum Scilla, *Br.;* Pilula Scillæ Composita, *Br.;* Pilula Ipecacuanhæ cum Urginea, *Br.;* Pilula Urgineæ Composita, *Br.*

AMMONII BENZOAS. U. S., Br.

AMMONIUM BENZOATE Ammon. Benz.

"Ammonium Benzoate, when dried for twenty-four hours over sulphuric acid, contains not less than 98 per cent. of $C_6H_5.COONH_4$." *U. S.* "Ammonium Benzoate, $NH_4C_7H_5O_2$, may be obtained by neutralising benzoic acid with solution of ammonia." *Br.*

Ammoniæ Benzoas; Ammonium Benzoicum; Benzoas Ammonicus; Benzoate of Ammonia; Benzoate d'Ammoniaque, *Fr. Cod.;* Benzöesaures Ammonium, Ammonium benzoat, *G.;* Benzoato amonico, *Sp.*

The process for the preparation of this salt was omitted in the latter editions of the U. S. P. The process of U. S., 1870, is appended. "Take of Benzoic Acid *two troyounces;* Water of Ammonia *three fluidounces and a half,* or a *sufficient quantity;* Distilled Water *four fluidounces.* Dissolve the Acid in three fluidounces and a half of the Water of Ammonia, previously mixed with Distilled Water; evaporate with a gentle heat, occasionally adding Water of Ammonia, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat." *U. S.*, 1870.

Although the quantity of ammonia ordered in the formula is in excess, yet, from the feeble action between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate would be formed, if it were not that a little solution of ammonia is from time to time added during or near the close of the evaporation, so as to maintain the alkali in slight excess. The crystals, for the same reason, should be dried without heat. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by means of bibulous paper.

Description and Physical Properties.—"Thin, white, laminar crystals or a crystalline powder, gradually losing ammonia on exposure to air.

It is odorless, or has a slight odor of benzoic acid. One Gm. of Ammonium Benzoate is soluble in 10 cc. of water, 35.5 cc. of alcohol, and in 8 cc. of glycerin, at 25° C.

"When Ammonium Benzoate is heated to about 200° C., ammonia and benzoic acid are given off. An aqueous solution of Ammonium Benzoate (1 in 10) responds to the reactions for ammonium, and for benzoates. An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus paper. Ash: not more than 0.05 per cent. Acidulate 10 cc. of an aqueous solution of the salt (1 in 50) with hydrochloric acid, and filter: the filtrate meets the requirements of the test for *heavy metals.*

"**Assay.**—Dry about 0.5 Gm. of Ammonium Benzoate for twenty-four hours over sulphuric acid, weigh accurately, and dissolve in 10 cc. of distilled water in a separator. Add to the solution 5 cc. of diluted sulphuric acid, and extract the liberated benzoic acid by shaking out with three successive portions of 25, 15 and 10 cc., respectively, of chloroform, passing the chloroform solution through a filter previously moistened with chloroform, and removing any benzoic acid adhering to the stem of the funnel and filter paper with a few cc. of chloroform. Evaporate the chloroform solution at a temperature not above 40° C. to about 5 cc., add 25 cc. of a mixture of equal volumes of neutralized alcohol and distilled water, and titrate this solution with tenth-normal barium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal barium hydroxide corresponds to 0.01391 Gm. of $NH_4C_7H_5O_2$.

"Preserve in well-closed containers, in a cool place." *U. S.*

"Colorless lamellar crystals. Taste saline, slightly acrid. Soluble in 6 parts of *water,* and in 30 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts. An aqueous solution yields a pale reddish precipitate on the addition of *T. Sol. of ferric chloride.* A strong aqueous solution, to which a little *hydrochloric acid* is added, yields a crystalline precipitate of benzoic acid. Completely volatilised by heat. If 1 gramme is dissolved in 20 millilitres of *water* and excess of *nitric acid* added, a crystalline precipitate of benzoic acid separates, the filtrate from which remains clear on the addition of *solution of barium chloride,* and does not become more than slightly opalescent on the addition of *solution of silver nitrate. Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Gmelin states that by boiling its solution the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Handbook,* xii, 38.)

Uses.—Ammonium benzoate owes its virtues chiefly to the benzoic acid radical. (See *Acidum Benzoicum.*) Like the other benzoates it is of service in the treatment of various forms of *rheumatism,* but is especially prized as an urinary antiseptic in fermentative *cystitis.* It has the great advantage in this condition that not only is the benzoic acid directly antiseptic but, because the ammonium radical is destroyed in the body, the salt also tends to increase the acidity of the urine, thereby aiding in the antibacterial effects of other agents.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

AMMONII BROMIDUM. U. S., Br.

AMMONIUM BROMIDE Ammon. Brom.

"Ammonium Bromide, when dried for twenty-four hours over sulphuric acid, contains not less than 98.5 per cent. of NH_4Br." *U. S.* "Ammonium Bromide may be obtained by neutralising hydrobromic acid with solution of ammonia. When dried at 100° C. it contains not less than 98 per cent. of pure ammonium bromide, NH_4Br." *Br.*

Ammonium Bromatum; Bromhydrate d'Ammoniaque, *Fr. Cod.;* Bromure d'Ammonium, *Fr.;* Ammonium bromatum, *P. G.;* Ammonium bromid, Brom-Ammonium, *G.;* Bromuro di ammonio, *It.;* Bromuro amonico, *Sp.*

Ammonium bromide may be made by dissolving bromine in ammonia water; but the U. S. Pharm., 1870, preferred the method of first forming solution of ferrous bromide, precipitating with ammonia water, separating by filtration the ferric oxide, and obtaining by evaporation the ammonium bromide from the solution. This process is similar to that by which potassium bromide is prepared. Charles Rice (*A. J. P.,* 1873, p. 249) recommends making ammonium bromide by double decomposition between hot solutions of potassium bromide and ammonium sulphate, assisting the precipitation of potassium sulphate by alcohol. W. H. Pile (*Proc. A. Ph. A.,* 1874, p. 434) published a simple process for this salt. Pour the bromine (one pound) carefully into four times its weight of distilled water in a stone jar, add *very gradually* about one quart of solution of ammonia, cover the top of the jar with a glass plate when vapors arise, and when all the ammonia has been added, and the solution is free from the odor of bromine, it is evaporated and the salt granulated; the yield is about twenty ounces.

Properties.—Ammonium bromide may be obtained in colorless crystals; on exposure to the air it gradually becomes yellowish, in consequence of a partial decomposition, by which hydrobromic acid appears to be liberated, as it now changes litmus red. The salt has a saline, pungent taste. Exposed to heat, it sublimes unchanged.

It is officially described as follows:

Description and Physical Properties.—"Colorless crystals, or a white, crystalline or granular powder, having no odor. It is somewhat hygroscopic. One Gm. of Ammonium Bromide is soluble in 1.3 cc. of water and in 12 cc. of alcohol, at 25° C. One Gm. is soluble in 0.9 cc. of boiling water and in 1.2 cc. of boiling alcohol. When heated, Ammonium Bromide volatilizes without fusing. An aqueous solution of the salt (1 in 10) responds to the reactions for ammonium, and for bromides.

"An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus paper. Add 2 cc. of nitric acid to about 2 Gm. of Ammonium Bromide, evaporate the mixture to dryness in a porcelain dish on a water bath, and ignite: not more than 0.05 per cent. of residue remains. Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20), and shake the mixture: the chloroform does not acquire a violet tint (*iodide*). Drop 1 cc. of diluted sulphuric acid upon about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*). A blue color is not immediately produced on adding potassium ferrocyanide T.S. to 20 cc. of an aqueous solution of the salt (1 in 250) (*iron*). Add 1 cc. of potassium sulphate T.S. to 10 cc. of an aqueous solution of Ammonium Bromide (1 in 20) acidulated with hydrochloric acid: no turbidity is produced immediately (*barium*). The addition of barium chloride T.S. to a similar solution of the salt acidulated with hydrochloric acid produces no turbidity (*sulphate*). An aqueous solution of the salt meets the requirements of the test for *heavy metals*.

"**Assay.**—Proceed as directed under the assay for bromides, using about 0.4 Gm. of Ammonium Bromide, previously dried for twenty-four hours over sulphuric acid, and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.009796 Gm. of NH_4Br. Each Gm. of Ammonium Bromide, previously dried, corresponds to not less than 100.5 cc. and not more than 103.4 cc. of tenth-normal silver nitrate.

"Preserve in well-closed containers." *U. S.*

"Small colorless crystals. Taste somewhat pungent, saline. Soluble in 1.5 parts of *water*, and in 13 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts and of bromides. Loses not more than 1 per cent. of its weight when dried at 100° C. 0.5 gramme of this dried salt dissolved in *water* requires for complete precipitation not less than 50.5 and not more than 51.5 millilitres of *N/10 solution of silver nitrate* (limit of impurities). Completely volatilised by heat. Yields no characteristic *reactions* for iron, bromates, iodides, or nitrates, and not more than the slightest *reaction* for sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

The incompatibilities are those of the bromides (see *Potassii Bromidum*), or of ammonium salts in general (see *Ammonii Chloridum*).

Uses.—Ammonium bromide is useful chiefly for the action of its bromic ion. (See under *Potassii Bromidum.*) By some it is believed to be less prone to cause disturbances of the digestion than is potassium bromide Theoretically the ammonium ion should impart to this salt a stimulant action upon the circulation and upon the spinal cord, but for reasons pointed out elsewhere (see *Ammonii Carbonas*) it is doubtful whether this is of any practical importance.

Dose, ten to thirty grains (0.6–1.9 Gm.) well diluted.

Off. Prep.—Elixir Ammonii Bromidi, *N. F.;* Elixir Bromidorum Trium, *N. F.;* Elixir Bromidorum Quinque, *N. F.;* Syrupus Bromidorum, *N. F.;* Syrupus Thymi Compositus, *N. F.*

AMMONII CARBONAS. U. S., Br.

AMMONIUM CARBONATE Ammon. Carb.

"Ammonium Carbonate consists of acid ammonium carbonate (NH_4HCO_3) and ammonium carbamate ($NH_4NH_2CO_2$) in varying proportions, and yields not less than 30 per cent. and not more than 32 per cent. of NH_3." *U. S.* "Ammonium Carbonate is a variable mixture of ammonium hydrogen carbonate, NH_4HCO_3, with ammonium carbamate, $NH_4NH_2CO_2$. It may be obtained by heating ammonium sulphate or chloride with calcium carbonate." *Br.*

Ammoniæ Carbonas, *Br.* 1867; Ammoniæ sesquicarbonas; Carbonas Ammonicus; Alkali Volatile Concretum; Volatile Salt, Sal Volatile; Carbonate d'Ammoniaque, *Fr. Cod.;* Alcoli volatil concret, Sel volatil d'Angleterre, *Fr.;* Ammonium carbonicum, *P. G.;* Ammonium-carbonat, Kohlensaures Ammonium, Flüchtiges Laugensalz, Reines Hirschhornsalz, *G.;* Carbonato di ammonio, *It.;* Carbonato amonico, *Sp.*

There have been many methods of obtaining ammonium carbonate, in all of which the ammonia originated in organic decomposition. It was probably originally prepared from putrid urine, and it is sometimes made in Scotland now from this source. A patent was taken out in England for manufacturing it from guano, and another for making it by the direct combination of its constituents, the carbon dioxide and ammoniacal gases being introduced simultaneously into leaden chambers. (*Chem. News,* Dec. 29, 1865.) At present the salt is manufactured by subliming a mixture of either ammonium chloride or sulphate with chalk. Ammonium chloride and chalk (calcium carbonate) are heated together in iron pots or retorts, and sublimed into large earthen or leaden receivers. By the reciprocal action of the salts employed, the carbon dioxide of the chalk unites with the ammonia of the chloride, generating ammonium carbonate, and the hydrochloric acid with the lime, forming water and calcium chloride. The carbonate and water sublime together as hydrated ammonium carbonate, and the residue is calcium chloride,

$$\begin{aligned} 4NH_4Cl + 2CaCO_3 = {} & \\ & NH_4HCO_3NH_4NH_2CO_2 + NH_3 \\ & + 2CaCl_2 + H_2O. \end{aligned}$$

The relative quantities of chalk and ammonium chloride, for mutual decomposition, are 50 of the former and 53.5 of the latter, or one molecule of each. But a great excess of chalk is usually taken, in order to insure the perfect decomposition of the ammonium chloride, any redundancy of which would sublime with the carbonate and render it impure. Barium carbonate is sometimes used in place of calcium carbonate, barium chloride, the by-product, having a greater commercial value than calcium chloride.

Ammonium sulphate may be substituted for the chloride with much economy, as was shown by Payen. This double decomposition between ammonium sulphate and calcium carbonate takes place in the dry way only—that is, by sublimation. In the wet way, the double decomposition is reversed, ammonium carbonate and calcium sulphate reacting so as to form ammonium sulphate and calcium carbonate. Large quantities of this carbonate are manufactured indirectly from *coal gas liquor* and *bone spirit,* the ammoniacal products in these liquors being converted successively into ammonium sulphate, chloride, and carbonate. (See *Ammonii Chloridum.*) The salt as first obtained has a slight odor of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be purified, which is effected in iron pots surmounted with leaden heads. The American carbonate has almost supplanted the English article, which was formerly used exclusively.

Description and Physical Properties.—"White, hard, translucent, columnar masses, having a strong odor of ammonia, without empyreuma, and a sharp, ammoniacal taste. On exposure to the air, the salt loses both ammonia and carbon dioxide, becoming opaque, and is finally converted into friable, porous lumps, or a white powder. For medicinal purposes, use only the translucent portions. One Gm. of Ammonium Carbonate is very slowly soluble in 4 cc. of water at 25° C. It is decomposed by hot water, with the evolution of carbon dioxide and ammonia. By prolonged boiling with water, the salt is completely decomposed and volatilized. Alcohol dissolves the carbamate, leaving the acid carbonate.

"When heated, Ammonium Carbonate is volatilized without charring, the vapor being strongly alkaline to moistened litmus paper. An aqueous solution of the salt (1 in 20) effervesces with acids, and is alkaline to litmus paper.

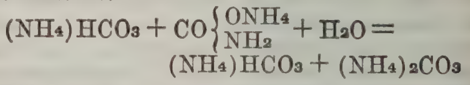
"When heated until volatilized, not more than 0.05 per cent. of residue remains. An aqueous solution of the salt (1 in 50) to which a slight excess of hydrochloric acid has been added meets the requirements of the test for *heavy metals,* A 10 cc. portion of an aqueous solution of the salt (1 in 20) on the addition of a slight excess of silver nitrate T.S., followed by a slight excess of nitric acid does not assume a brown color (*thiosulphate*). A 2 Gm. portion of the salt shows no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid, and no more *sulphate* than corresponds to 0.1 cc. of fiftieth-normal sulphuric acid. Add a slight excess of nitric acid to an aqueous solution containing 1 Gm. of the salt, and evaporate to dryness on a water bath: a colorless, odorless residue is obtained (*empyreumatic matter*).

"**Assay.**—Place in a weighing bottle about 10 cc. of distilled water, tare the bottle and its contents, add about 2 Gm. of unaltered, translucent Ammonium Carbonate, and weigh accurately. Transfer the contents of the bottle to a 200 cc. flask, add 50 cc. of normal sulphuric acid, and, when solution is effected, titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

"Preserve in well-closed containers, in a cool place." *U. S.*

"Translucent, crystalline masses. Ammoniacal odor; taste pungent, ammoniacal. Alkaline to *litmus.* Soluble in 4 parts of *water.* Exposed to the air it becomes covered with a white efflorescence which is only superficial; this efflorescence should be scraped off before the salt is used for dispensing. Yields the *reactions* characteristic of ammonium salts and of carbonates. 1 gramme dissolved in 40 millilitres of *water* requires for neutralisation not less than 18.0 millilitres of *N/1 solution of sulphuric acid.* Completely volatilised by heat. Yields not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. When its aqueous solution is neutralised with a mineral acid and evaporated to dryness, the residue is colorless and odorless (absence of tarry matters)." *Br.*

If commercial ammonium carbonate be treated with 90 or 91 per cent. alcohol, it is decomposed into the two salts of which it is composed, ammonium carbamate going into solution while the acid ammonium carbonate remains undissolved. This latter compound also remains undissolved when the commercial carbonate is treated with an amount of water insufficient for complete solution. The result of the complete solution of the commercial salt in water is a mixture of acid and neutral carbonates, the carbamate having been decomposed according to the reaction:



$$(NH_4)HCO_3 + CO\left\{\begin{matrix}ONH_4\\NH_2\end{matrix}\right. + H_2O = (NH_4)HCO_3 + (NH_4)_2CO_3$$

When long or insecurely kept, it gradually passes into a bicarbonate, becoming opaque and friable, and falling into powder. When heated in a porcelain dish the commercial carbonate should evaporate without residue, and, if turmeric paper held over it undergoes no change, it has passed into bicarbonate. As prepared from coal gas liquor, it sometimes contains traces of tarry matter, which give a dark color to its solution in acids, but a refined carbonate, made by resubliming the commercial article, is now in the market. For papers on testing commercial ammonium carbonate, see *A. J. P.,* 1890, p. 500, by G. M. Beringer; also *Ph. Era,* 1889, p. 417, by Charles C. Abbey.

Uses.—Locally ammonium carbonate is an active irritant and capable in overdose of causing gastritis. Systemically its action is purely that of its ammonium radical. When injected into the circulation in proper dose ammonium acts as a rapid but fugacious stimulant to both the circulation and nervous system. The blood pressure is elevated partly from an effect on the cardiac muscles and probably also in part from a stimulation of the vasomotor center in the medulla. After toxic doses the rise in blood pressure may be followed by a fall to a point below the norm. There is also an increase in the rapidity of breathing due to an action upon the respiratory center. The action upon the spinal cord is shown by increased activity of reflexes and in sufficient doses it is capable of causing in the lower animals tetanic convulsions. These effects are caused only when it is introduced fairly rapidly into the circulation and do not occur, at least to any practical degree, when the drug is exhibited by the mouth, because the ammonium is so rapidly destroyed in the system that it is scarcely possible for a sufficient quantity to be absorbed through the mucous membrane of the alimentary tract to obtain the necessary concentration in the blood for its physiological effect. It is oxidized in the liver appearing in the urine chiefly as urea, although a small amount seems to be excreted as nitric acid. The irritant salts of ammonium, however, by virtue of their local effects on mucous membranes reflexly, may excite the medullary centers. To this action is due the improvement in circulation and respiration seen in cases of syncope as the result of smelling or swallowing such salts as the carbonate or hydroxide.

Ammonium carbonate is used as an antacid in the treatment of various forms of *gastric disturbances,* especially when associated with *headache.* It is also employed for its expectorant effect. It is probably largely converted in the stomach into the chloride and exercises the same type of action in *bronchitis* as that salt. As a rapid stimulant in cases of *circulatory failure,* as in adynamic *pneumonias, snake-bite,* and other conditions it may prove of great value if administered hypodermically.

Coarsely bruised with the addition of half its bulk of stronger ammonia water, and scented with oil of lavender, it constitutes the common *smelling-salts,* so much used as a nasal stimulant in *syncope* and *hysteria.* It should never be given in powder or in pill, on account of its volatile nature and its irritant action on the mucous membrane.

Ammonium carbonate is sometimes employed in making effervescing draughts, 20 grains of the salt requiring for this purpose 6 fluidrachms of lemon juice, 24 grains of citric acid, or 25½ grains of tartaric acid. It is sometimes used as a leavening agent, replacing sodium bicarbonate in culinary operations and is then usually called *baker's ammonia.*

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Spiritus Ammoniæ Aromaticus, *U. S., Br.;* Mistura Pectoralis, Stokes, *N. F.*

AMMONII CHLORIDUM. U. S., Br.

AMMONIUM CHLORIDE Ammon. Chlor.

"Ammonium Chloride, when dried for twenty-four hours over sulphuric acid, contains not less than 99.5 per cent. of NH_4Cl." *U. S.* "Ammonium Chloride, NH_4Cl, may be obtained by neutralising crude solution of ammonia or ammonium carbonate with hydrochloric acid, and purifying the product." *Br.*

Ammonium Muriaticum, Chlorhydras Ammoniæ; Chloretum Ammonicum, Sal Ammoniacum, Ammoniæ Hydrochloras, s. Murias; Sal Ammoniac, Hydrochlorate of Ammonia; Chlorure d'Ammonium, *Fr. Cod.;* Chlorhydrate d'Ammoniaque, Sel Ammoniac, *Fr.;* Ammonium Chloratum, *P. G.;* Ammoniumchlorid, Salmiak, Chlorammonium, Reiner (gereinigter) Salmiak, *G.;* Chlorurio d'ammonio, Sale ammoniaco, *It.;* Cloruro amonico, Sal amoniaco, *Sp.*

In the U. S. Pharmacopœia of 1870 both the crude and the purified ammonium chloride were official, under the names *Ammonii Chloridum* and *Ammonii Chloridum Purificatum.* The U. S. P. VIII recognized but one, *Ammonii Chloridum,* but it transferred this title, which formerly was given to the crude sal ammoniac, to the purified salt, without giving a process for preparing it. The U. S. P. X has retained this plan. The U. S. P., 1870, process is as follows: "Take of Chloride of Ammonium, in small pieces, *twenty troyounces;* Water of Ammonia *five fluidrachms;* Water *two pints.* Dissolve the Chloride of Ammonium in the water, in a porcelain dish, with the aid of heat; add the Water of Ammonium, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring at a moderate heat, until it granulates." *U. S.,* 1870.

This process is used to free the salt from ferric chloride, a frequent impurity of the crude product, derived from the subliming vessels.

Ammonium chloride originally came from Egypt, where it was obtained by sublimation from the soot resulting from the burning of camels' dung, which is used in that country for fuel, and it is still to be found in the Indian bazaars in an impure state as it has been obtained from the unburnt residue in the interior of brick-kilns in which camel's manure is used for fuel. The name amonia is derived from the fact that it was largely thus obtained in the Libyan desert near the temple of Jupiter Ammon. It has long been known in China, where it is obtained from the water of certain volcanic springs, and exists in commerce in various states of purity. It is found in the fumaroles of Vesuvius, Etna, Hecla, and other volcanoes, and in the cracks and fissures in recent lava streams.

Preparation.—At present ammonium chloride is derived from the ammonia liquor, called *gas liquor,* found in the condensing vessels of coal gas works. It is obtained in lesser amount from the brown, fetid ammonia liquor, known under the name of *bone spirit,* which is a secondary product, obtained from the destructive distillation of bones, in the manufacture of bone black. These two liquors are the chief sources of ammonia compounds, for they are both used to procure ammonium sulphate, and this salt is employed directly or indirectly for obtaining all the other salts of ammonium. A third source of increasing importance is its production as a by-product in ovens for coking coal. Other sources in the past were stale urine, coal soot, guano, peat, and bituminous schist.

Gas liquor contains ammonium carbonate, cyanide, sulphide, and sulphate, but principally the carbonate. It is saturated with sulphuric acid, and the solution obtained, after due evaporation, furnishes brown crystals of ammonium sulphate. These are then sublimed with sodium chloride in iron pots lined with clay and furnished with an iron dome or head. By the mutual action of the sulphate and chloride, there are formed ammonium chloride which sublimes, and sodium sulphate which remains behind. Thus:

$$(NH_4)_2SO_4 + 2NaCl = 2NH_4Cl + Na_2SO_4$$

Gas liquor is usually distilled with lime with the aid of column stills, whereby a relatively pure and strong solution of ammonia is obtained.

This may be further purified, however, from empyreumatic matter by treatment with potassium permanganate and then driven over by heat and absorbed in hydrochloric acid. In this way, as the solution becomes concentrated, the sal ammoniac crystallizes out in the bottom of the leaden tanks in which the absorption takes place. Impure sal ammoniac may be purified either by crystallization or by sublimation. In the latter case the sal ammoniac is placed in an iron subliming pot coated with a composition of clay, sand, and charcoal and covered with a dome of lead, iron, earthenware, or glass. These pots are sometimes sufficiently large to hold 500 pounds. A gentle fire is kept up under the subliming pot for seven or eight days, when, the dome having cooled down, and the sal ammoniac somewhat contracted, so as to loosen from the sides, the dome is thrown off from the iron pot, and about two or three hundred-weight of white, semi-transparent sal ammoniac is obtained.

In the destructive distillation of bones for making bone black, the distilled products are the bone spirit already mentioned, being chiefly an aqueous solution of ammonium carbonate, and an empyreumatic oil, called animal oil. Ammonium chloride may be obtained from the bone spirit in the manner just described for procuring it from gas liquor. Sometimes, however, the ammonium sulphate is not made by direct combination, but by digesting the bone spirit with ground plaster of Paris. By double decomposition, ammonium sulphate and calcium carbonate are formed. The ammonium sulphate is then converted into the chloride by sublimation with common salt.

Properties.—Commercial ammonium chloride is a white, transparent, tough, fibrous salt, occurring in large cakes about two inches thick, convex on one side and concave on the other, due to the shape of the dome of the subliming apparatus; the pieces are frequently tinged on the surface with iron stains, from the iron dome which is used for crude sal ammoniac. It has a pungent, saline taste, but no odor. Its sp. gr. is 1.45. This salt is very difficult to powder in the ordinary way. Its pulverization, however, may be readily effected by making a boiling saturated solution of the salt and stirring it as it cools. The salt is thus made to granulate, and in this state, after draining from the remaining solution and drying, may be easily powdered. At a red heat it sublimes without decomposition or residue. Exposed to a damp atmosphere it becomes slightly moist. It has the property of increasing the solubility of corrosive sublimate in water. It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths—the former disengaging hydrochloric acid, the latter ammonia, both sensible to the smell. Ammonium chloride is usually employed for obtaining gaseous ammonia, which is conveniently disengaged by lime.

Description and Physical Properties.—" A white, crystalline or granular powder, without odor, and having a cooling, saline taste. It is somewhat hygroscopic. One Gm. of Ammonium Chloride is soluble in 2.6 cc. of water, 100 cc. of alcohol, and in 8 cc. of glycerin, at 25° C. One Gm. is soluble in 1.4 cc. of boiling water.

" Ammonium Chloride on ignition is volatilized without fusing. An aqueous solution of the salt (1 in 10) responds to the reactions for ammonium, and for chlorides. An aqueous solution of the salt (1 in 20) does not show an immediate acid reaction with 1 drop of methyl orange T.S. An aqueous solution of Ammonium Chloride meets the requirements of the test for *heavy metals.* Acidulate 10 cc. of an aqueous solution of the salt (1 in 10) with hydrochloric acid and add a few drops of ferric chloride T.S.: no red color should be produced (*thiocyanate*). Add 2 cc. of nitric acid to 2 Gm. of the salt, and evaporate the mixture to dryness in a porcelain dish on a water bath: a white residue is obtained which, when ignited, yields not more than 0.1 per cent. of *non-volatile substances.*

" **Assay.**—Proceed as directed under the assay for chlorides, using about 0.2 Gm. of Ammonium Chloride, previously dried for twenty-four hours over sulphuric acid and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.005350 Gm. of NH_4Cl." *U. S.*

" Colorless, inodorous crystals. Taste saline, cooling. Soluble in 3 parts of *water,* and in 60 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts and of chlorides. Completely volatilised by heat. Yields no characteristic *reactions* for copper, carbonates, or nitrates, and not more than the slightest *reactions* for iron, or for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

It is incompatible with lead acetate and silver nitrate, producing precipitates respectively of lead and silver chlorides.

It is also incompatible with all alkali and alkali earth hydroxides and carbonates which gradually decompose it by liberating NH_3. This incompatibility is shared by all salts of ammonium.

Uses.—Ammonium chloride possesses the stimulant properties of its basic ion and probably differs but little in its physiological action from the carbonate, although it is believed by some to be less powerful and less fugacious. Clinically it is employed chiefly in the treatment of various types of *bronchitis* for the purpose of increasing the secretions. Its effect in these conditions is probably owing chiefly to its "salt action," a property common to most of the nontoxic salts. Some believe, however, that it exercises a specific stimulant effect upon mucous membranes not only of the lungs but also of the digestive organs. It has been used, therefore, in the treatment of *acute hepatitis, catarrhal jaundice,* and *gastric catarrh,* and with asserted good results. For its old use in *sciatica, dysmenorrhea,* and *glandular enlargements* there is little scientific support, and it has been almost entirely abandoned for these purposes.

Hermann Beigel, of London, strongly recommends its inhalation in the nascent state, resulting from a mixture of the two gases composing it. Three bottles are used, one containing ammonia water, the second an equivalent quantity of liquid hydrochloric acid, and the third half filled with water, connected with the first two by tubes, and supplied itself with a tube for inhalation. By inhalation the patient draws the two gases from their respective bottles into the third, where they combine to form ammonium chloride, which is freed from any excess of either gas by the water. Another mode of inhaling ammonium chloride is in *spray,* by means of the atomizer; ten to twenty grains are dissolved for the purpose in a fluidounce of water. Ammonium chloride has been used in some European countries in place of sodium chloride for salting food before eating it.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Trochisci Ammonii Chloridi, *U. S.*

AMMONII HYPOPHOSPHIS. N. F.

AMMONIUM HYPOPHOSPHITE Ammon. Hypophos.

"Ammonium hypophosphite contains, when dried over sulphuric acid for twenty-four hours, not less than 97.5 per cent. of $NH_4PH_2O_2$ (83.10)." *N. F.*

Description and Physical Properties.—"Ammonium Hypophosphite occurs in deliquescent, colorless, hexagonal plates, or as a granular powder, odorless and having a saline and bitter taste. One gram dissolves in about 1 cc. of water, and in about 20 cc. of alcohol at 25° C.; very soluble in boiling water or boiling alcohol.

"When heated, the salt is decomposed with the evolution of hydrogen phosphide, which is spontaneously inflammable. An aqueous solution of the salt (1 in 20) is neutral or slightly acid to litmus and when heated with sodium hydroxide T.S. gives off ammonia. An aqueous solution of the salt (1 in 20) slightly acidulated with sulphuric acid, yields with silver nitrate T.S. a white precipitate, which rapidly turns brown or black through the separation of metallic silver. A similar portion of the solution, slightly acidulated with sulphuric acid, yields, on heating with copper sulphate T.S. a reddish brown precipitate.

"Ten cc. of an aqueous solution of the salt (1 in 20) remains clear for five minutes after the addition of 5 cc. of ammonium oxalate T.S. and a few drops of ammonia water (*calcium salt*). Add 1 cc. of calcium chloride T.S. to 10 cc. of the aqueous solution of the salt (1 in 20) previously acidulated with 1 cc. of acetic acid; no turbidity is produced (*oxalate*). An aqueous solution of salt does not respond to the Test for heavy metals. Boil 5 cc. of an aqueous solution of the salt (1 in 25) with 3 cc. of sodium hydroxide solution until the ammonia is expelled, add 5 cc. of nitric acid, and evaporate to dryness on a water bath; the residue meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 0.2 Gm. of Ammonium Hypophosphite, previously dried over sulphuric acid for twenty-four hours and accurately weighed in 10 cc. of distilled water, add 3 cc. of sodium hydroxide T.S. and boil until the ammonia is expelled. Then add 5 cc. of nitric acid and evaporate the solution to dryness on a water bath. Add 1 cc. of nitric acid and again evaporate it to dryness on a water bath. Dissolve the residue in 20 cc. of distilled water, transfer it to a 200 cc. graduated flask, add a drop of phenolphthalein T.S. and sufficient sodium hydroxide T.S. (free from chloride) to produce a pink color, and then add 100 cc. of tenth-normal silver nitrate and agitate well. Now gradually add zinc oxide (free from chloride) in small portions until the liquid is neutral to litmus, and then sufficient distilled water to make the mixture measure 200 cc. Agitate the mixture thoroughly, filter it through a dry filter and collect 100 cc. of the filtrate (representing one-half of the Ammonium Hypophosphite taken). Add to this 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate used corresponds to 0.00277 Gm. of $NH_4PH_2O_2$. Each Gm. of Ammonium Hypophosphite corresponds to not less than 352.0 cc. of tenth-normal silver nitrate.

"Preserve it in well-closed containers." *N. F.*

Uses.—The peculiar advantages of this salt are not evident. It is recommended particularly in the latter stages of *bronchitis* and *laryngitis.*

Dose, two to five grains (0.13–0.3 Gm.) every two or three hours.

Off. Prep.—Syrupus Ammonii Hypophosphitis, *N. F.*

AMMONII PHOSPHAS. N. F.

AMMONIUM PHOSPHATE Ammon. Phos.

"Ammonium phosphate contains diammonium hydrogen phosphate [$(NH_4)_2HPO_4 = 132.13$] and ammonium dihydrogen phosphate ($NH_4H_2PO_4 = 115.09$), corresponding to not less than 22 per cent. of combined ammonia ($NH_3 = 17.03$)." *N. F.*

Ammoniæ Phosphas; Phosphate of Ammonia; Phosphas Ammonicus; Phosphate d'Ammoniaque, *Fr.;* Ammonium Phosphoricum; Phosphorsaures Ammoniak, *G.*

The *diammonium hydrogen phosphate* was formerly official, under the name of ammonium phosphate, in both the United States and British Pharmacopœias. The preparation recognized at present, by the N. F., is a mixture of this salt with the more acid ammonium di-hydrogen phosphate.

The process formerly given in the British Pharmacopœia involved treating diluted phosphoric acid with stronger ammonia water until the solution was slightly alkaline, then evaporating until crystals formed on cooling, ammonia being added from time to time in order to maintain constantly a slight excess of this base. Without such a precaution a portion of the more acid phosphate will be formed owing to the escape of the ammonia during the process of evaporation. "Neutral" ammonium phosphate prepared in this way is a white salt, crystallizing in six-sided tables, efflorescent, insoluble in alcohol, and soluble in four parts of cold water. The solution has an alkaline, somewhat saline taste, and an alkaline reaction, and gives off ammonia when heated.

The acid phosphate, $NH_4H_2PO_4$, is obtained by boiling a solution of the neutral phosphate so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water.

The ammonium phosphate of commerce is a mixture of these two phosphates and hence corresponds more closely with the N. F. definition.

Description and Physical Properties.—"Ammonium Phosphate occurs in colorless crystals, or as a white crystalline powder, losing ammonia on exposure to the air. One Gm. dissolves in about 4 cc. of water; it is insoluble in alcohol. The aqueous solution (1 in 20) is neutral or alkaline to litmus.

"Separate portions of an aqueous solution of the salt (1 in 20) yield with magnesia mixture T.S. a white precipitate, with silver nitrate T.S. a yellow precipitate, and, upon warming with ammonium molybdate T.S., a yellow precipitate.

"Dissolve 1 Gm. of Ammonium Phosphate in 20 cc. of distilled water; the resulting solution is not more than slightly turbid (*calcium, aluminum*). Ten cc. of an aqueous solution of the salt (1 in 100) acidulated with nitric acid, is not rendered more than slightly opalescent by silver nitrate T.S. (*chloride*). Ten cc. of an aqueous solution of Ammonium Phosphate (1 in 100), mixed with 2 cc. of hydrochloric acid is not rendered turbid at once by the addition of a few drops of barium chloride T.S. (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals. Five cc. of a solution of Ammonium Phosphate in diluted nitric acid (1 in 25) heated with 1 cc. of sulphuric acid until fumes of sulphur trioxide appear, meets the requirements of the Test for arsenic.

"**Assay.**—Transfer about 1 Gm. of Ammonium Phosphate, accurately weighed, to a distilling flask, dissolve it in 200 cc. of distilled water and add 25 cc. of an aqueous solution of sodium hydroxide (1 in 4). Connect the flask with a small glass condenser, the lower outlet tube of which is inserted beneath the surface of 50 cc. of half-normal sulphuric acid, contained in a flask of about 500 cc. capacity, and distil the liberated ammonia into the acid. Titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as an indicator, and calculate the percentage of ammonia in the salt. Each cc. of half-normal sulphuric acid corresponds to 0.008515 Gm. of NH_3. Each Gm. of Ammonium Phosphate corresponds to not less than 23.5 cc. of half-normal sulphuric acid.

"Preserve it in well-closed containers in a cool place." *N. F.*

Uses.—Many years ago this salt was introduced as a remedy for *gout* and *rheumatism* on the supposition that it increased the solubility of uric acid in the urine, a hypothesis which as far as we know has not been established. The salt is retained in the National Formulary chiefly because it is an ingredient in the compound syrup of phosphates known popularly as "chemical food."

Dose, from five to thirty grains (0.32–1.9 Gm.), three or four times a day, dissolved in a tablespoonful of water.

Off. Prep.—Liquor Phosphatum Compositus, *N. F.*

AMMONII SALICYLAS. U. S.

AMMONIUM SALICYLATE Ammon. Salicyl.

"Ammonium Salicylate, when dried for twenty-four hours over sulphuric acid, contains not less than 98 per cent. of $NH_4C_7H_5O_3$." *U. S.*

Ammonium Salicylicum; Salicylate d'Ammoniaque, *Fr.;* Ammoniumsalicylat, Salicylsaüres Ammonium, *G.*

This salt may be made by adding salicylic acid to ammonia water until the acid is in slight excess, then evaporating the solution (which should be slightly acid to litmus paper) and crystallizing. Care should be used to prevent contamination with iron, which would give the product a pinkish or reddish tinge, and overheating, which would cause decomposition, evidenced by a phenol-like odor.

Description and Physical Properties.—"Colorless, lustrous, monoclinic prisms, or plates, or a white, crystalline powder. It is odorless, and has at first a slightly saline, bitter taste, with a sweetish after-taste. It is stable in dry air. One Gm. of Ammonium Salicylate is soluble in 1 cc. of water and in 3 cc. of alcohol, at 25° C.

"When heated, Ammonium Salicylate fuses with decomposition, giving off inflammable vapors and the odor of phenol, and is finally volatilized. Ammonium Salicylate responds to the reactions for ammonium, and for salicylates. An aqueous solution of the salt (1 in 10) is colorless and neutral or slightly acid to litmus paper. Ash: not more than 0.1 per cent. Acidulate 10 cc. of an aqueous solution of Ammonium Salicylate (1 in 50) with hydrochloric acid, and filter: the filtrate meets the requirements of the test for *heavy metals.*

"**Assay.**—Dry about 0.5 Gm. of Ammonium Salicylate over sulphuric acid, weigh accurately, and dissolve in 10 cc. of distilled water in a separatory funnel. Add to the solution 5 cc. of diluted sulphuric acid, and extract the liberated salicylic acid by shaking out with three successive portions of 25, 15 and 10 cc., respectively, of chloroform, passing the chloroform solutions through a filter previously moistened with chloroform, and removing any salicylic acid adhering to the stem of the funnel and filter paper with a few cc. of chloroform. Evaporate the chloroform solution to about 5 cc., add 25 cc. of a mixture of equal volumes of neutralized alcohol and distilled water, phenolphthalein T.S. being used as indicator, and titrate this solution with tenth-normal barium hydroxide. Each cc. of tenth-normal barium hydroxide corresponds to 0.01551 Gm. of $NH_4C_7H_5O_3$.

"Preserve in well-closed containers, protected from heat and light." *U. S.*

Uses.—Ammonium Salicylate is one of the best forms of administering salicylic acid. For consideration of its uses, see under *Acidum Salicylicum.*

Dose, ten to twenty grains (0.65–1.3 Gm.).

AMMONII VALERAS. N. F.

AMMONIUM VALERATE Ammon. Valer.

[Ammonium Valerianate]

"Ammonium valerate is a compound of ammonia with valeric acid having a somewhat varying composition." *N. F.*

Valerianas Ammonicus; Ammonium Valerianicum, *Fr. Cod.;* Valérianate d'Ammoniaque, *Fr.;* Baldriansaures (Valeriansaures) Ammonium, Ammoniumvalerianat, *G.;* Valerianato amonico, *Sp.*

A process for preparing this salt is no longer official; that of the United States Pharmacopœia of 1870 will be found in the *United States Dispensatory,* 18th ed., p. 163.

The official, as well as the commercial, salt is not the normal valerate but is an acid salt with an approximate formula of $NH_4C_5H_9O_2 + 2C_5H_{10}O_2$; the neutral salt is obtained only with difficulty, is in prismatic crystals, and is easily liquefied by moderate temperatures.

Description and Physical Properties.—"Ammonium Valerate occurs in colorless, or white, quadrangular plates, emitting the odor of valeric acid; it is deliquescent in moist air, and has a sharp and sweetish taste. One Gm. of Ammonium Valerate dissolves in 0.3 cc. of water and in 0.6 cc. of alcohol at 25° C.; soluble in ether.

"An aqueous solution of the salt (1 in 20) is acid to litmus and when heated with potassium hydroxide T.S. evolves ammonia. Supersaturate slightly a concentrated aqueous solution of Ammonium Valerate with sulphuric acid; an oily layer of valeric acid rises to the surface.

"Precipitate completely 10 cc. of an aqueous solution of the salt (1 in 20) with ferric chloride T.S.; the filtrate does not possess a deep red color (*acetate*). When heated, the salt fuses, gives off vapors of ammonia and valeric acid, and is finally volatilized, leaving not more than 0.05 per cent. of residue. An aqueous solution of the salt (1 in 50), when slightly acidulated with hydrochloric acid and filtered through a small, wetted filter, does not respond to the Test for heavy metals.

"Preserve it in well-closed containers." *N. F.*

Uses.—On the theory that valerian owed its activity to valeric acid the ammonium valerate was brought forward many years ago as a nerve sedative in *hysteria, epilepsy, neuralgia,* and other nervous affections. Physiologically, however, it is practically inert and any beneficial result which may have followed its administration in these conditions may more reasonably be attributed to the psychic effect than to any direct action upon the nervous system. *Pierlot's solution* should be made by dissolving a drachm of valeric acid and thirty-two drachms of distilled water, saturating the solution with ammonium carbonate, and adding to the salt formed forty grains of the alcoholic extract of valerian. The solution of Pierlot is neutral, color brown, odor of valerian strong. It contains one twenty-fifth of its weight of the pure salt. The dose is six to thirty minims (0.4–1.8 cc.), given in water or on a lump of sugar.

Dose, of ammonium valerate, two to ten grains (0.13–0.6 Gm.).

Off. Prep.—Elixir Ammonii Valeratis, *N. F.*

AMYGDALA AMARA. Br.

BITTER ALMOND

"Bitter Almond is the ripe seed of Prunus Amygdalus, *Stokes, var.* amara, *Baill.*" *Br.*

Semen Amygdali Amarum; Amandes amères, *Fr. Cod.;* Amygdalæ, Amaræ, *P. G.;* Bittere Mandeln, *G.;* Mandorle amare, *It.;* Almendra amarga, *Sp.*

The almond tree resembles the cherry. The leaves are elliptical, petiolate, minutely serrated, and are of a bright green color. The flowers are large, of a pink color varying to white, with very short peduncles, and petals longer than the calyx, and usually stand in pairs upon the branches. The fruit is a drupe with the outer covering thin, tough, dry, downy, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, containing the kernel or almond.

There are several varieties of this species of *Amygdalus,* differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The two most important are the var. *dulcis* and the var. *amara,* the former bearing sweet, the latter bitter almonds. Both of these varieties have been known since ancient times. The var. *dulcis* yields the hard and paper-shelled variety. The latter, owing to the thin endocarp, is particularly suitable for table use. Another variety grows wild in Turkestan and has a nearly smooth endocarp or "stone." The almond tree is a native of sub-tropical China, Persia, Syria, Asia Minor and probably also Turkestan. It is now cultivated not only in the Orient, but in the Mediterranean countries of southern Europe and northern Africa, and also in southern England, Scandinavia and California. Bitter almonds are chiefly imported from Morocco and Sicily.

Bitter Almond.—This seed is smaller than the sweet almonds, and "resembles the Sweet Almond in general appearance, but is distinguished by being shorter and proportionally broader, by its bitter taste, and by the characteristic odor resembling that of prussic acid given off by its aqueous emulsion." *Br.*

They have the bitter taste of the peach kernel, and, though when dry, inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain nearly the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they also contained hydrocyanic acid and volatile oil, to which their peculiar taste and odor and their peculiar operation upon the system were ascribed. These principles do not pre-exist in the almond, but result from the decomposition of a glucoside denominated *amygdalin,* $C_{20}H_{27}O_{11}N$, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron in 1830, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. It is decomposed by the action of diluted acids or, in the presence of water, by the nitrogenous ferments, like *emulsin,* which accompany it in the bitter almond. Liebig and Wöhler give the following process for obtaining amygdalin, in which the object of the fermentation is to destroy the sugar with which it is associated: Bitter almonds, previously deprived of their fixed oil by pressure, are boiled in successive portions of alcohol till exhausted. From the liquors thus obtained all the alcohol is drawn off by distilation, care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connection with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposit it upon cooling. If pure, it will form a perfectly transparent solution with water. Any oil which it may contain may be separated by washing with ether. One pound of almonds yields approximately 120 grains of amygdalin. (*Ann. Pharm.,* xxii, 329.)

Amygdalin, or cyanogenetic glucosides, of similar composition and effect, appear to be extensively diffused in plants, having been noticed not only in the different genera of the *Rosaceæ,* as *Amygdalus, Cerasus,* and *Prunus,* but also by Wicke in various *Pomaceæ,* as *Pyrus Malus, Sorbus Aucuparia, Sorbus hybrida, Sorbus torminalis, Amelanchier vulgaris, Cotoneaster vulgaris,* and *Cratægus Oxyacantha.* (*Ann. Ch. Ph.,* lxxix, 79.) The cyanogenetic glucosides are a related group of compounds which eventually hydrolyze to prussic acid, benzaldehyde and glucose. Their relationship may be illustrated by the products of hydrolysis of amygdalin.

$$C_{20}H_{27}NO_{11} + H_2O = C_6H_{12}O_6 + C_{14}H_{17}O_6N$$

This last, *mandelonitrile glucoside,* forms glucose, benzaldehyde, and hydrocyanic acid.

$$C_{14}H_{17}O_6N + H_2O = C_6H_{12}O_6 + C_7H_6O + CNH$$

Mandelonitrile glucoside occurs in three isomeric forms, *sambunigrin* found in elder flowers; *prulaurasin* found in cherry laurel; and *l-mandelonitrile* (also known as *amygdinitrile,* or *Fischer's glucoside*) found in wild cherry bark. All of these are optically active, being laevo-rotary, but vary in the degree of rotation. According to Power and Moore (*Tr. Chem. Soc.,* 1909, p. 243) they are combinations of dextro-, racemic and laevo-mandelonitrile respectively. According to the researches of Johannen, the emulsin is contained in the radicle and plumule, and in the vascular bundles of the cotyledons, while the parenchyma of the cotyledons contains the amygdalin. (*P. J.,* March, 1888.) Sweet almonds contain the ferment emulsin but not the glucoside amygdalin.

Certain substances have the effect of preventing the reaction between amygdalin and emulsin among which are alcohol and acetic acid. It is asserted that emulsin procured from other seeds, as those of the poppy, hemp, and mustard, is capable of producing the same reaction between water and amygdalin, though in a less degree. (*Ann. Pharm.*, xxviii, 290.) Amygdalin appears not to be poisonous when taken pure in the stomach, unless there be emulsin in the food in the stomach.

Bitter almonds yield their fixed oil by pressure, and at the present time this oil is an article of commerce, and is frequently sold as expressed oil of almond, this being now officially permitted. It is usually produced from North African bitter almonds; the volatile oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. (See *Oleum Amygdalæ Amaræ.*)

Uses.—Bitter almonds are used solely for their flavoring powers. For medicinal purposes the oil is preferable. (See *Oleum Amygdalæ Amaræ.*) It has been ascertained that bitter almond paste, and other substances which yield the same volatile oil, such as bruised cherry-laurel leaves, peach leaves, etc., have the property of destroying the odor of musk, camphor, most of the volatile oils, creosote, cod liver oil, the balsams, etc.; and Mahier, a French pharmacist, has employed them successfully to free mortars and bottles from the odor of asafetida and other substances of disagreeable odor. All that is necessary is first to remove any oily substance by means of an alkali, and then to apply the paste or bruised leaves.

Bitter almonds, on account of the hydrocyanic acid developed in them, are poisonous.

AMYGDALA DULCIS. Br.

SWEET ALMOND Amygd. Dulc.

"Sweet Almond is the ripe seed of Prunus Amygdalus, *Stokes, var.* dulcis, *Baill.* Known in commerce as the Jordan almond." *Br.*

Semen Amygdali Dulce; Amandes douces, *Fr. Cod.*; Amygdalæ Dulces, *P. G.*; Süsse Mandeln, *G.*; Mandorle dolci, *It.*; Almendra dulce, *Sp.*

For description of the almond tree see *Amygdala Amara.*

We are supplied with sweet almonds chiefly from Spain, Italy, France, and Southern California. They are separated into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the *Jordan* and *Valencia* almonds, the former imported from Malaga, the latter from Valencia. The former are longer, narrower, more pointed, and more highly esteemed than the latter.

Properties.—Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. Deprived of this covering they are called *blanched almonds.* On exposure to the air they are apt to become rancid; but, if thoroughly dried and kept in well-closed glass vessels, they may be preserved unaltered for many years.

Sweet almonds, when blanched, are without odor, and have a sweet, very pleasant taste, which has rendered them a favorite article of diet in all countries where they are readily attainable.

"About two and a half centimeters or somewhat more in length, nearly oblong in outline, more or less compressed, pointed at one extremity and rounded at the other. Testa cinnamon-brown, thin and scaly. Seed exalbuminous, containing two large planoconvex oily cotyledons. Taste bland; when triturated with *water* forms a white emulsion with no marked odor." *Br.*

The U. S. IX gave the following description of the microscopic appearance. "The powder is creamy-white, exhibiting numerous very small oil globules, 0.001 mm. or less in diameter, and larger oil globules and crystalloids, the latter sometimes with adhering globoids; fragments of parenchyma of endosperm, containing oil globules and aleurone grains; also occasional fragments of seed-coat with characteristic, more or less scattered, large, elliptical, thin-walled, strongly lignified epidermal cells and narrow, closely spiral tracheæ. Starch grains are absent." *U. S. IX.*

Shelled Almonds are sometimes substituted by the kernels of the peach, plum and apricot. The stone cells in the epidermal layer of the almond are much larger than in the kernels of the substitutes. For microscopic distinctions see Winton and Moeller, *"The Microscopy of Vegetable Foods."* Almond cake, a by-product in the manufacture of almond oil, is largely used in the preparation of a class of detergent powders known as "almond meal." It is also used as a diabetic food and sometimes as an adulterant of ground spices and powdered drugs. By the analysis of Boullay, it appears that almonds contain 54 parts of fixed oil, 24 of protein, 6 of uncrystallizable sugar, 3 of gum, 9 of fibrous matter, 3.5 of water, and 0.5 of acetic acid, comprising loss. The protein is somewhat peculiar, consisting of *amandin* and *emulsin,* the latter being an enzyme. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a siphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution has an acid reaction, and, if heated to 100° C., becomes opaque and milky, and gradually deposits a snow-white precipitate, amounting to about 10 per cent. of the protein employed. The distinguishing characteristic of the emulsin is that of producing certain changes noticed previously in amygdalin, which property it loses when its solution is boiled, although not by exposure in the solid state to a heat of 100° C. It consists of nitrogen, carbon, hydrogen, and oxygen, with a minute proportion of sulphur, and is probably identical with the *synaptase* of Robiquet. L. Portes has reported asparagin in sweet almonds. (*N. R.*, January, 1877.) The fixed oil is described under the head of *Oleum Amygdalæ Expressum,* to which the reader is referred. Sweet almonds, when rubbed with water, form a milky emulsion, free from the odor of hydrocyanic acid, the insoluble matters being suspended by the agency of the albuminous, mucilaginous, and saccharine principles.

Uses.—Sweet almonds have no other influence on the system than that of a nutrient and demulcent. The emulsion formed by triturating them with water is a pleasant vehicle. From their nutritive properties, and the absence of starch in their composition, they are valuable used in the diet of *diabetics.* Care must be taken when almond meal is directed to be taken as a food product, as in diabetes, that neither bitter almond meal, which is poisonous, or the factitious product, which contains soap and is inedible, is supplied. *Almond meal* or almond press cake is used for cosmetic purposes as an addition to the bath or to the water used in washing the face and hands. Much of the so-called almond meal used for this purpose is factitious or adulterated.

AMYLIS NITRIS. U. S. (Br.)

AMYL NITRITE Amyl. Nitris

"Amyl Nitrite contains not less than 80 per cent. of $C_5H_{11}NO_2$." *U. S.* "Amyl Nitrite is a liquid obtained by the interaction of amylic alcohol [which has been distilled between 128° and 132° C.] and nitrous acid. It consists chiefly of iso-amyl nitrite, $C_5H_{11}NO_2$, but contains also other nitrites of the homologous series. It should be kept in small, stoppered bottles in a cool, dark place." *Br.*

Amyl Nitris, *Br., U. S.,* 1890; Nitris Amylicus; Amylonitrous Ether, Amylæther Nitrosus; Ether amylnitreux, Ether amylazoteux, Azotite d'Amyl, *Fr.;* Amylium Nitrosum, *P. G.;* Amynitrit, *G.;* Etere isoamilnitroso, *It.;* Nitrito de amilo, *Sp.*

This substance, which was discovered by Balard in 1844, should not be confounded with *amyl nitrate,* $C_5H_{11}NO_3$, which is not used as a medicine.

Preparation.—Amyl nitrite may be prepared by passing a stream of nitrous acid (hyponitric acid) gas through purified amyl alcohol at a temperature of 132° C., or by acting upon amyl alcohol with nitric acid, as originally suggested by Balard. The amyl alcohol should always first be purified by agitating it with an equal bulk of strong solution of common salt, then distilling in a retort with a thermometer, collecting what comes over between 125° C. and 140° C., and redistilling this until it has a boiling point near 132° C. The purified alcohol should be mixed with about an equal bulk of nitric acid in a capacious glass retort, being gradually heated until it approaches boiling, when the fire is to be removed. As soon as a thermometer inserted into the tubulures rises above 100° C. the receiver is changed, because both ethyl-amylic ether and amyl nitrate at such temperatures come over freely and would contaminate the product. The distillate obtained below 100° C. is agitated with a solution of potassium carbonate, and the oily liquid which separates is very slowly heated in a clean retort to 96° C., then the receiver is changed and the distillate collected as before, until the thermometer reaches 100° C. That which comes over between the two temperatures is pure amyl nitrite. It is essential to this process that in every case the heating be very gradual.

Amyl nitrite is also manufactured by distilling a mixture of amylic alcohol, sodium nitrite, and diluted sulphuric acid,

$$2C_5H_{11}OH + 2NaNO_2 + H_2SO_4 = 2C_5H_{11}NO_2 + Na_2SO_4 + 2H_2O.$$

Other methods of preparation will be found in the *U. S. D.*, 20th edition, page 140. W. H. Greene (*A. J. P.*, 1879, p. 65) shows that *nitropentane* (an isomer of amyl nitrite) is almost invariably a constituent of amyl nitrite, and he believes that commercial amyl nitrite is frequently put upon the market unrectified, specimens examined having boiling points varying from 70° C. to 180° C. J. M. Francis examined amyl nitrite of commerce in 1905 and found many samples of inferior grade. He stated that 80 per cent. of the total volume should distil between 90° C. and 100° C.

Dustan and W. Lloyd Williams (*P. J.*, 1888, p. 487) have shown that the supposed pure amyl nitrite is a mixture of α-amyl nitrite and β-amyl nitrite, arising from the fact that the amyl alcohol used is always a mixture of α-amyl alcohol and β-amyl alcohol in varying proportions. They find the α-amyl nitrite to be optically inactive and to boil at 97° C., while β-amyl nitrite has dextro-rotatory power and boils at about 94° C. Much of the commercial amyl nitrite also contains isobutyl nitrite, boiling at 67° C. It is a question whether the physiological action of commercial amyl nitrite is really due to the amyl nitrite or to impurities, especially to the isobutyl nitrite, but the experiments of Brunton and Bokenham (*P. J.*, xix, 490) indicated that the commercial, impure nitrite is stronger than either pure α- or β-amyl nitrite. According to Bals and Broglio, the *tertiary amyl nitrite* differs from amyl nitrite in not giving rise to toxic symptoms, and in being slightly hypnotic.

Description and Physical Properties.—"A clear, yellowish liquid, having a peculiar, ethereal, fruity odor, and a pungent, aromatic taste. It is volatile even at low temperatures, and is inflammable. Amyl Nitrite is almost insoluble in water, but is miscible with alcohol and with ether.

"Specific gravity: 0.865 to 0.875 at 25° C. Add 2 cc. of sulphuric acid to a mixture of 2 drops of Amyl Nitrite and 2 drops of water: amyl valerate is produced, recognized by its odor on dilution with water. Add a few drops of Amyl Nitrite to a mixture of 1 cc. of ferrous sulphate T.S. and 5 cc. of diluted hydrochloric acid: a greenish-brown is produced.

"Mix 1 cc. of normal sodium hydroxide and 10 cc. of distilled water with a drop of phenolphthalein T.S. in a glass-stoppered cylinder, and add 5 cc. of Amyl Nitrite. After inverting the cylinder a few times, the red tint of the aqueous layer is still perceptible (*free acid*). To a mixture of 1.5 cc. of silver nitrate T.S. and 1.5 cc. of alcohol, add a few drops of ammonia T.S. until the precipitate first formed is redissolved. Then add 1 cc. of Amyl Nitrite, and gently heat for one minute: the mixture does not become brown or black (*aldehyde*).

"Preserve in hermetically-sealed glass bulbs, or in tightly-stoppered vials, in a cool place, protected from light." *U. S.*

"A volatile liquid of a yellowish color, fragrant odor, and not more than the faintest acid reaction. Almost insoluble in *water;* soluble in *alcohol* (90 per cent.) in all proportions. Specific gravity 0.870 to 0.880. Not less than 90 per cent. distils below 100° C. A mixture of 5 volumes with sufficient *alcohol* (90 per cent.) to form 100 volumes yields a liquid of which a portion tested in a nitrometer as described under 'Spiritus Ætheris Nitrosi' yields not less than 7.9 times its volume of nitric oxide gas. On shaking with an equal volume of *solution of sodium hydroxide* the aqueous portion acquires not more than a pale yellow color (limit of aldehyde). Remains transparent when cooled to 0° C. (absence of water)." *Br.*

Assay.—"Transfer about 3 cc. of Amyl Nitrite, which has been previously shaken with 0.5 Gm. of potassium bicarbonate and carefully decanted, to a 100 cc. flask, tared with about 20 cc. of alcohol, and weigh accurately. Add sufficient alcohol to bring the volume to exactly 100 cc., and mix thoroughly. Introduce into a nitrometer, page 437, exactly 10 cc. of the alcoholic solution, wash any adhering Amyl Nitrite into the nitrometer with 5 cc. of alcohol, followed by 10 cc. of potassium iodide T.S., and afterwards by 5 cc. of diluted sulphuric acid. When the volume of gas has become constant (in about thirty to sixty minutes), note the amount collected, multiply this volume in cc. by 4.8, and divide the product by the weight of the Amyl Nitrite taken. At standard temperature and pressure, the quotient represents the percentage of Amyl Nitrite in the liquid. The temperature correction is 1/273 of the total percentage just found for each degree, additive if the temperature is below 25° C., and subtractive if it is above 25° C. The barometric correction is 1/760 of the total percentage just found for each millimeter, additive if it is above 760 mm., and subtractive if it is below 760 mm." *U. S.*

Uses.—Physiologically, amyl nitrite acts precisely like sodium nitrite (see *Sodii Nitris*), except that it is much quicker and more evanescent. Amyl nitrite is used in medicine for three purposes: To relax spasms in the arteries, to control convulsions, and for the relief of the asthmatic paroxysm. In all its usages it is to be borne in mind that its action while extremely rapid is very fleeting and it is therefore of service only where an immediate effect is desired. In the circulatory conditions in which it is of service the most important is *angina pectoris.* This disease is probably associated with spasms of the coronary arteries, but whatever be its pathology, clinical experience has demonstrated the extreme value of inhalations of amyl nitrite. In convulsive disorders, amyl nitrite is of service only when it is necessary to cause immediate relaxation; thus in *tetanus,* because of the duration of the convulsive tendency, the fugaciousness of its action renders it of relatively small service; on the other hand, in *strychnine poisoning,* by restraining the convulsions long enough for more durable motor depressants to act, it may prove a life-saving remedy. In ordinary *epilepsy* it is of little service, but in that condition known as *status epilepticus* in which the patient passes from one convulsion to another, the drug may be of great benefit. Again, in those occasional cases of epilepsy in which the seizure is preceded by an aura of sufficient length, if the patient carry in the pocket pearls of amyl nitrite and inhale the vapor as soon as the aura commences the paroxysm may usually be aborted. In many cases of *asthma* it will cause an immediate, if only temporary, cessation of the paroxysm. Whether this effect is due to the action of the nitrite radical upon the circulation or whether it is the result of some narcotic effect of the amyl group is at present uncertain.

The claim of Hare that amyl nitrite is of great value for the relief of *hemoptysis* has been confirmed by a number of observers. (See *B. M. J.*, July 15, 1911.) Its action in this condition is probably the result of dilatation of the splanchnic and contraction of the pulmonary blood-vessels.

Amyl nitrite is generally administered by inhalation, usually in doses of from three to five drops, although much larger quantities have been given without bad results. The rule is to commence with three drops on a handkerchief held close to the nose, and then gradually to increase *pro re nata.* The handkerchief should always be withdrawn so soon as the face flushes or the heart begins to become excited, as the effects always increase for some time, even if no more be inhaled. The best method, however, of administering the very volatile liquid is by the use of glass pearls—small flask-shaped vessels containing two, five, or ten minims of the nitrite; these are crushed in a handkerchief or towel when wanted for inhalation, the thin and fragile glass causing no inconvenience. The drug may also be given by the mouth.

When inhaled in doses of from five to ten drops, amyl nitrite produces in man violent flushing of the face, accompanied with a feeling as though the head would burst, and a very excessive action of the heart. Along with these symptoms, after a larger quantity, there is a sense of suffocation, and more or less marked muscular weakness. We know of no case of serious poisoning from amyl nitrite in man.

Dose, from three to five minims (0.2–0.3 cc.), if given by mouth it may be dissolved in alcohol.

AMYLUM. U. S., Br.

STARCH Amyl. [Corn Starch]

"Starch consists of the granules separated from the grain of *Zea mays* Linné (Fam. *Gramineæ*). Starch contains but a trace of organic foreign matter and yields not more than 0.5 per cent. of ash, and not more than 14 per cent. of moisture." *U. S.* "Starch is procured from the grains of (1) common wheat, Triticum sativum, *Lam.;* (2) maize, Zea Mays, *Linn.;* and (3) rice, Oryza sativa, *Linn.*" *Br.*

Amylum, *P. G.;* Amylum Zeæ, Wheat Starch; Amidon, Fécule, Empois, *Fr.;* Stärkmehl, Stärkes, Kraftmehl, Maisstärke, Weizenstärke, *G.;* Amido, *It.;* Almidon, *Sp.*

Starch is a proximate vegetable principle contained in most plants and especially abundant in the various grains, such as corn, wheat, rye, and barley; in seeds, as peas, beans, chestnuts, acorns, etc.; and in numerous rhizomes and tuberous roots, as those of the potato, the sweet potato, the arrow-root, canna, cassava, sago, yam, curcuma and erythronium. The starch is always in the form of grains, which are contained within the parenchymatous cells, and is procured by reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine grains which are held in suspension have subsided. This, when dried, is starch, more or less pure, according to the care taken in conducting the process. In the U. S. P. of 1880 the official starch was that derived from wheat, but in the revision of 1890 corn starch was recognized, and has been since. In most of the European Pharmacopœias the official starch is derived from wheat. In some of them rice is also recognized. The starch of European commerce is largely obtained from the potato, while in the United States corn starch is almost exclusively in use, wheat and rice starch coming next in importance. For a description of the differences, see page 132.

Properties.—Starch is white, inodorous and tasteless, pulverulent, opaque, and, as found in commerce, is usually in columnar or irregular angular masses (wheat starch), which are easily reduced to powder, which produces a peculiar sound when pressed between the fingers. Its specific gravity is 1.505 at 19.4° C. (Payen.) It is composed of minute microscopic granules, in starch from the same plant nearly uniform in size, more or less plainly striate, and having a distinct hilum or point of origin of growth. In the different species of plants the starch granules differ in their characteristic forms. When exposed to a moist air, it absorbs a considerable quantity of water, which may be driven off by a gentle heat. It is insoluble in alcohol, ether, and cold water, but unites with boiling water, which, on cooling, forms with it a soft, semi-transparent paste or a gelatinous, opaline solution according to the proportion of starch employed. The paste placed on folds of blotting-paper, renewed as they become wet, loses water, contracts, and assumes the appearance of horn. If the proportion of starch be very small, the solution, after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Heating with glacial acetic acid to 100° C., or with glycerin to 190° C., will also make starch soluble.

Corn starch is officially described as:

"In irregular, angular white masses or in fine powder; consisting chiefly of polygonal, rounded or spheroidal starch grains from 0.003 to 0.035 mm. in diameter and usually with a lenticular or 3- to several-rayed central cleft; inodorous; taste characteristic, slight. Starch is insoluble in cold water and in alcohol. The individual grains of Starch are colored a deep blue by iodine T.S. Boil 1 Gm. of Starch with 15 cc. of water: upon cooling, a translucent, whitish jelly forms. Triturate about 0.5 Gm. of Starch with 5 cc. of distilled water: the mixture is neutral to litmus paper. Add 10 cc. of distilled water to 1 Gm. of Starch, and acidify with 0.5 cc. of hydrochloric acid: the mixture should show no blue color within five minutes on the addition of 3 drops of potassium ferrocyanide T.S. (*iron*)." *U. S.*

"In fine powder or in irregular angular or columnar masses, which are readily reduced to powder; white, inodorous. Cold *water* mixed with an equal weight of Starch does not become more than faintly acid or alkaline to *litmus.* Boiled with *water* and cooled, it gives a deep blue color with *N/10 solution of iodine.* Under the microscope the several varieties of Starch present the following characters:—1. Wheat Starch: A mixture of large and small granules, the former lenticular in shape, and marked with faint concentric striæ surrounding a nearly central hilum. 2. Maize Starch: Granules more uniform in size, frequently polygonal, somewhat smaller than the large granules of wheat starch, and having a very distinct hilum, but without evident concentric striæ. 3. Rice Starch: Granules extremely minute, nearly uniform in size, polygonal, without evident hilum or striæ. Starch is free from granules other than those described." *Br.*

At a temperature of 160° C. for air-dried starch, and 200° C. for starch previously dried at 100° C., it is changed into dextrin, and at 200° C. to 215° C. forms a transparent fused mass, which consists exclusively of dextrin (Payen); at 220° C. to 230° C. it undergoes further change and yields chiefly *pyrodextrin,* a brown, tasteless, and odorless compound, readily soluble in water, insoluble in alcohol and ether. (Gelis, *Ann. Ch. Phys.,* (3) lii, 388.)

Composition and Nature.—The formula of starch is generally taken as $C_6H_{10}O_5$, or a multiple of this. This formula does not give us a clear idea of the nature of the starch grain. It consists of at least two or three substances. The wall or membrane is very distinct and clearly differentiated from the rest of the grain. The inner portion consists of two substances which are distributed in alternate layers. The one is colloidal, taking up aniline stains, and the other is made up of soluble starch. (See Kraemer, *A. J. P.,* 1907, pp. 217 and 412; 1914, p. 81.)

Recent determinations of its molecular weight by Brown and Morris make it as high as $5(C_{12}H_{20}O_{10})_{20}$. Iodine forms with starch, whether in its original state or in solution, a blue compound; and a solution of iodine is the most delicate test for its presence. The color varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine be in excess, it is blackish-blue; if the starch, violet blue. This reaction is not altogether characteristic of starch; Barger and Starling (*P. J.,* 1912, xcii, 146) have compiled a list of over sixty organic substances which give a blue color with iodine. A singular property of starch iodide is that its solution becomes colorless if heated to about 93.5° C., and afterwards recovers its blue color upon cooling. By boiling, the color is permanently lost, while Puchot states that certain nitrogenized organic bodies, as albumin, prevent the reaction of iodine on starch or destroy it. Alkalies unite with starch, forming soluble compounds, which are decomposed by acids, the starch being precipitated. It is thrown down from its solution by lime water and baryta water, forming insoluble compounds with these earths. The solution of lead subacetate precipitates it in combination with the oxide of the metal. Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. By long boiling with diluted sulphuric, hydrochloric, or oxalic acid, it is converted into dextrin and dextrose. A similar conversion into dextrin and glucose is effected by means of diastase, which change can be represented as taking place in several stages:

$$3C_6H_{10}O_5 + H_2O = \underset{\text{Dextrin}}{C_{12}H_{20}O_{10}} + \underset{\text{Dextrose}}{C_6H_{12}O_6}$$

$$C_{12}H_{20}O_{10} + H_2O = \underset{\text{Maltose}}{C_{12}H_{22}O_{11}}$$

$$C_{12}H_{22}O_{11} + H_2O = \underset{\text{Dextrose}}{2C_6H_{12}O_6}$$

Many observers claim to recognize the production of other intermediate substances, as *amylodextrin* (soluble starch), *erythrodextrin, achroodextrin, maltodextrin,* none of which reduce Fehling's solution, followed by *maltose,* which does reduce Fehling's solution. Strong hydrochloric and nitric acids dissolve starch; and the latter acid, by the aid of heat, converts it into oxalic and malic acids. By the action of strong nitric, sulphuric, or crystallizable acetic acid, used with certain precautions, the starch is rendered soluble, and may be obtained in this state by separating the acid by means of alcohol. By the continued action of concentrated sulphuric acid it is decomposed. When it is dissolved in strong nitric acid, and precipitated by water, a white powder is thrown down, called *xyloidin,* $C_6H_9(NO_2)O_5$ (Braconnot), in which one atom of the hydrogen of the starch is replaced by one group, NO_2, furnished by the nitric acid. Leulier (*J. P. C.,* 1918, xviii, 291) makes soluble starch by boiling together for fifteen minutes a mixture of 100 Gm. of 95 per cent. alcohol, 5 Gm. of sulphuric acid and 25 Gm. of starch. It is then transferred to a filter and washed with cold water or alcohol until free from acid. The product thus obtained is a white powder, insoluble in cold water but readily soluble in warm water. Mixed with hot water and exposed to a temperature of 27° C., starch undergoes chemical changes, which result in the formation of several distinct principles, among which are sugar, a gummy substance (perhaps dextrin), and a soluble modification of starch. With yeast, starch undergoes the vinous fermentation, being, however, first converted into sugar. All plants which contain chlorophyll have the power of using the chemical rays of sunlight in producing from carbon dioxide and water a substance which is organic. There is first formed in the center of the chlorophyll granule a minute speck, which is believed to be starch; this new starch granule is incapable of solution, but by conversion into sugar or dextrin is rendered soluble, and in this form is carried in the juices of the plant. One of two destinies there awaits it. It may be converted into the permanent compound cellulose which constitutes the woody tissue, or it may be reconverted to its original form and be deposited in the buds, seeds, barks, roots or rhizomes of the plant. These stores of starch are usually accumulated for future growth, and are especially seen in plants which flower in the spring before the leaves are put forth, or which reproduce the species without seeding.

The structure and nature of the starch granule has been the subject of much investigation and discussion. Its microscopic appearance supports, but of course does not prove, the original theory advanced by Schleiden, that it is composed of concentric layers of similar chemical composition, in which the outer layer has been the first formed while the inner layers have been successively deposited in its interior. The microscopic characters, however, are just as readily explained on the theory that the central layer was the first formed and that the peripheral layers have been deposited around the point of the hilum. This view, originally advanced by Fritsche in 1834, has been widely supported by various observers. Other authorities have come to the conclusion that the starch grains grow as do ordinary vegetable cells, but the theory brought forward in 1880 by Schimper, that all starch grains develop within plastids, *i.e.*, in protoplasmic masses or cells, and that in starch which is stored, the leucoplastids finally disappear, is the theory which has been of recent times most widely believed and is probably correct. In stating his views, Schimper further came to the conclusion that the outer portion of the grain is the part most recently produced. That there is a marked difference in the layers of the starch grains is shown by the varying effects of staining reagents, certain parts of the grains being much more affected by safranin and gentian-violet than others. It would further appear that though the starch layers each contain colloidal substances besides crystalloidal cellulose, the proportion of their constituents varies so much that the alternate layers are different, one set being colloidal and others crystalloidal, in their general nature. For details see Kraemer, *Botan. Gaz.*, xxiv, Nov., 1902; also *Proc. Am. Philosoph. Soc.*, xli.

Varieties.—Starch, as obtained from different substances, is somewhat different in its characters. *Wheat starch,* when examined with a microscope, is found to consist of more or less rounded or biscuit-shaped grains, from 0.005 to 0.035 mm. in diameter, the smaller being spheroidal, the larger rounded and flattened, and are without distinct markings, except when heated with chemical solutions. The granules are mixed with loose integuments, resulting from the process of grinding. This variety of starch has a certain degree of hardness and adhesiveness, owing, according to Guibourt, to the escape of a portion of the interior substance of the broken granules, which attracts some moisture from the air, and, thus becoming glutinous, acts as a bond between those which remain unbroken. Another opinion attributes this peculiar consistence to the retention of a portion of the gluten of the wheat flour, which causes the granules to cohere. The granules of *maize starch* are very small, with a diameter not exceeding, according to Payen, one-sixth of that of the potato, and little more than one-half of that of the wheat granules. They have a very distinct hilum which is either circular or in the form of a 3- to 5-rayed cleft, but no evident concentric striæ. *Rice starch* has extremely minute granules, nearly uniform in size, polygonal, without evident hilum or striæ. *Potato starch* is employed in various forms, being prepared so as to imitate more costly amylaceous substances, such as arrowroot and sago. In its ordinary state it is more pulverulent than is wheat starch, has a somewhat glistening appearance, and may be distinguished with the aid of the microscope, by the size of its granules, which are larger than those of any other known fecula except canna, or *tous les mois.* They are exceedingly diversified in size and shape, though their regular form is said to be ovate or shell-shaped, the grains varying from 0.005 to 0.125 mm. in long diameter. The characters of other kinds of starch will be given under the heads of the several official substances of which they constitute the whole or a part. According to Chevallier, starch is sometimes adulterated with calcium carbonate and calcium sulphate; and the fraud is also practised of saturating it with moisture, of which it will absorb 12 per cent. without any obvious change.

Several authors have reported upon the value of the micro-polariscope in the examination of commercial starches. (See Ewers, *Zeitschr. f. öffentl. Chem.*, 1908, pp. 8 and 150; Herman, *Bull. Soc. Chim. Belg.*, 1908, p. 340.) For a report on the ultra-microscopic structure of the starches, their constituents and a method of separating the latter, see *C. R. A. S.*, 1908, pp. 285, 599 and 978.

Uses.—Starch is demulcent and, when cooked, nutritive; in the raw state it is scarcely affected by human digestive secretions. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions and prevent excoriation. Mixed with water it forms the basis of several pastes used in dermatological practice. Dissolved in hot water, and allowed to cool, it is often employed in enemata, either as a vehicle, or as a demulcent application in irritated states of the rectum; this liquid may also be used as an antidote in iodine poisoning, and given freely in other cases where amylaceous or mucilaginous drinks are indicated. It is also used officially as a diluent for powdered extracts.

ANETHOL. N. F.

ANETHOL

"The methyl ether of para-propenyl phenol [$C_6H_4.C_3H_5.OCH_3 = 148.15$]. It is the main constituent in the oils of anise, star anise, and fennel, and is usually obtained from these by fractionating, chilling and crystallizing." *N. F.*

This principle is recognized by the N. F., as it is used in a number of preparations to impart the anise flavor.

Description and Physical Properties.—"Anethol is a colorless or faintly yellow, highly refractive liquid at a temperature of 23° C. or above, having a sweet taste and the aromatic odor of anise. At from 20° to 21° C. it solidifies to a white glistening, crystalline mass which remelts at from 22° to 23° C.

"Anethol is almost insoluble in water, readily soluble in ether or chloroform, and forms a clear solution with two volumes of alcohol. Specific gravity: 0.984 to 0.986 at 25° C. Boiling point: 235° to 236° C. Refractive index: 1.558 to 1.561 at 25° C.

"It is optically inactive or shows a deviation of not more than 0.08° in a 100 mm. tube at 25° C., due to a slight trace of the oil from which the Anethol has been prepared (if prepared from oil of anise this deviation will be lævorotatory, if from oil of fennel, dextrorotatory). Shake 10 cc. of Anethol with 50 cc. of a saturated aqueous solution of sodium bisulphite in a graduated cylinder and allow the mixture to stand for six hours. No appreciable diminution in the volume of Anethol will be observed nor does a crystalline deposit separate (*aldehydes*).

"Preserve it in well-stoppered, amber-colored bottles protected from light and air." *U. S.*

For further description, see under *Oleum Anisi.*

Dose, from one to five minims (0.06–0.3 cc.).

Off. Prep.—Elixir Anisi, *N. F.;* Pulvis Rhei et Magnesiæ Anisatus, *N. F.;* Spiritus Ammoniæ Anisatus, *N. F.*

ANETHI FRUCTUS. Br.

DILL FRUIT

"Dill Fruit is the dried ripe fruit of Peucedanum graveolens, *Benth. and Hook. f.*" *Br.*

Garden Dill, Dilly, Anet; Aneth, *Fr. Cod.;* Fenouil puant, *Fr.;* Dill, *G.;* Eneldo, *Sp.*

Peucedanum graveolens (*Anethum graveolens* L.), or garden dill, resembles the fennel plant, but is smaller. It is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed, branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Mediterranean countries and Southern Russia, and is found growing wild in various parts of Africa and Asia. It is cultivated in Germany, Roumania and England and has been introduced into our gardens. The whole plant is aromatic, the leaves are used as a flavor for soups, sauces and pickles. For a paper by J. C. Umney describing the commercial varieties, see *Year Book of Pharmacy,* 1898, 374. The seeds, as the fruit is commonly called, are the only part used. They are "composed of two mericarps usually separate and freed from the pedicel; each broadly oval, about four millimetres long, and two to three millimetres broad; brown; very strongly compressed dorsally; dorsal ridges inconspicuous, but the lateral ridges prolonged into paler brown wings. In transverse section, six vittæ in each mericarp. Odor and taste agreeably aromatic." *Br.* The latter property depends on a volatile oil, which is present in the fruits to the extent of 2.8 to 4 per cent. (See *Oleum Anethi.*) The bruised fruits impart their virtues to alcohol and to boiling water.

Indian dill fruit (*P. Sowa* Kurz) has recently appeared on the European market as a substitute for the genuine article. It may be distinguished from true dill fruit by being narrower and more convex, by the mericarps being usually coherent and by the pale color of the dorsal ridges of the mericarps.

Uses.—Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion.

Dose, of the fruit, from fifteen grains to a drachm (1–3.9 Gm.).

Off. Prep.—Aqua Anethi, *Br.*

ANGELICÆ FRUCTUS. N. F.

ANGELICA FRUIT Angel. Fruct.
[Angelica Seed]

"Angelica Fruit is the dried ripe fruit of *Angelica Archangelica* Linné and of other species of *Angelica.* (Fam. *Umbelliferæ.*) Angelica Fruit contains not more than 3 per cent. of foreign fruits, seeds or other foreign organic matter." *N. F.*

Off. Prep.—Pilula Antiperiodica, *N. F.;* Pilula Antiperiodica sine Aloe, *N. F.;* Tinctura Antiperiodica, *N. F.;* Tinctura Antiperiodica sine Aloe, *N. F.*

ANGELICÆ RADIX. N. F.

ANGELICA ROOT Angel. Rad.

"Angelica Root consists of the dried rhizome and roots of *Angelica Archangelica* Linné and of other species of *Angelica.* (Fam. *Umbelliferæ.*) Angelica Root contains not more than 5 per cent. of its stem basis or other foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

Angelique, *Fr. Cod.;* Racine d'Angelique, *Fr.;* Radix Angelicae, *P. G.;* Engelwurzel, *G.*

Two species of this genus are used in medicine, the *Angelica Archangelica* L. (*Garden Angelica*), a native of Europe, and the *A. atropurpurea* (*Masterwort*), which grows throughout the eastern United States. *Garden angelica* has a long, thick, fleshy, biennial root, furnished with many rootlets, and sending up annually a hollow, jointed, round, channelled, smooth, purplish stem, which rises five feet or more in height, and divides into numerous branches. The leaves are twice pinnate, and the flowers, which are greenish-white, are borne in compound umbels. The plant is a native of Europe and Asia and is commonly found in the high mountainous regions in the southern section of Europe, as in Switzerland and among the Pyrenees. It is often cultivated. The whole plant is aromatic, but the root only is official in the Swiss, Austrian, and German Pharmacopœias, while the fruit is official in the N. F. Angelica root is imported chiefly from Hamburg and London. The root should be dug up in the autumn of the first year, as it is then least liable to become mouldy and worm eaten. It is spindle-shaped, 4 to 6 cm. thick at the crown, and beset with long descending rootlets. The fresh root has a yellowish-gray epidermis, a freshly yellow parenchyma, and when wounded yields a honey-colored juice, having all the aromatic properties of the plant. The dried root is grayish-brown and much wrinkled externally, whitish and spongy within, and breaks with a starchy fracture, exhibiting shining resinous masses. It is very apt to be attacked by insects, and should be conserved by the addition of a few drops of chloroform or carbon tetrachloride.

Description and Physical Properties.—"*Unground Angelica Root.*—Rhizomes short and thick, 5 to 10 cm. long, sometimes split, frequently crowned with leaf and stem bases; roots numerous, 10 to 20 cm. long, 5 to 7 mm. thick at the base and gradually tapering to about 1 mm., frequently twisted or braided together; externally dark gray-brown to reddish or purplish brown; with deep furrows; fracture smooth and short. Odor aromatic; taste sweetish, pungent, aromatic, and bitter.

"*Structure.*—Bark, spongy, nearly as wide as the wood zone and with radial rows of brownish oleoresin canals; parenchyma of cortex with numerous starch grains; wood rays finely porous and more narrow than the medullary rays; pith distinct in the rhizome, absent in the root.

"*Powdered Angelica Root.*—Yellowish-brown; numerous, mostly simple, irregularly rounded starch grains up to 0.008 mm. in diameter, sometimes with a cleft at the center and occasionally two or more compound; tracheæ or fragments of tracheæ up to 0.075 mm. in width, with reticulate markings or large simple pores; brownish oil canals or fragments thereof, up to 0.250 mm. in width, sometimes with adjoining epithelial cells; fragments of parenchyma tissue with some of the cells filled with starch; fragments of large brownish cork cells; wood-fibers with thin walls and often with oblique markings; yellowish oil globules." *N. F.*

It has a strong odor and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acridity is dissipated by drying.

The constituents of the root are *angelic acid,* $C_5H_8O_2$, a monatomic acid of the acrylic series, valeric acid, $C_5H_{10}O_2$, resin, bitter principle, tannin, pectin, malic acid, sugar, starch and a volatile oil consisting largely of phellandrene. For further information concerning the constituents of this drug, see *U. S. D.,* 19th ed., p. 1386. *Schim. Rep.,* 1902, 15; 1911, 21; 1913, 26.

The *fruit* is officially described as follows: "*Unground Angelica Fruit.*—Cremocarps oval, externally pale yellowish brown, 4 to 8 mm. long, 3 to 6 mm. broad, 1 to 2 mm. thick; the base faintly notched; apex bearing 5 minute calyx-teeth and remains of the style; mericarps joined, or separate; each mericarp nearly flat on one surface, the latter bearing a central longitudinal groove, margins sharp, slightly upturned, convex upon the other surface and with 3 strong longitudinal ribs, the latter separated from one another by narrow grooves and from the margin by broader grooves; pericarp soft, tough and spongy; single-seeded. Odor characteristic and agreeable; taste aromatic, pungent, and sweetish.

"*Structure.*—Transverse sections of the mericarp pentangular in outline, the angles formed by the ribs which project outward, often 0.500 mm. or more; four of the sides of the mericarp being almost equal in length, the fifth or commissural surface being about three times as long as one of the dorsal sides and concave near the middle; a distinct fibrovascular bundle at each angle; epidermis composed of cells with the outer walls slightly thickened and rarely modified into short one-celled hairs; pericarp composed chiefly of soft spongy parenchyma and 10 to 30 oil-tubes, the latter situated close to the inner epidermis; seed coat thin with a yellowish brown pigment and enclosing an endosperm made up of parenchyma containing numerous fixed oil globules and aleurone grains, the latter containing rosettes of calcium oxalate.

"*Powdered Angelica Fruit.*—Light-brown; exhibiting numerous fragments of the characteristic spongy parenchyma with cells having many large simple pores; yellowish-brown pieces of the oil-tubes; fibro-vascular bundles and endosperm parenchyma containing fixed oil, and aleurone grains, the latter with rosettes, up to 0.011 mm. in diameter." *N. F.*

Angelica Fruit comes to the United States from Belgium, France and England. Most of it is used by essential oil firms.

Uses.—Angelica is one of those survivals of ancient superstition which attributed medicinal properties to so many aromatic herbs. The potency of the drug may be estimated by the fact that in Europe the root and stem are candied and eaten as a conserve.

There is probably no essential difference in the therapeutic value of the European and American species nor, indeed, is there any sufficient reason for believing that either drug possesses any therapeutic virtues beyond that of the mild aromatics.

Angelica root has been used as an aromatic in *flatulent colic* and also as a domestic diaphoretic and diuretic, and, occasionally externally as a counterirritant. The seeds were at one time supposed to possess *antimalarial* properties and are an ingredient of the *Tinctura Antiperiodica. N. F. From the fruit;* Pilulæ Antiperiodicæ, *N. F.;* Pilulæ Antiperiodicæ sine Aloe, *N. F.;* Tinctura Antiperiodicæ, *N. F.;* Tinctura Antiperiodicæ sine Aloe, *N. F.*

Dose, of either root or seeds, from fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Angelicæ Radicis, *N. F.*

ANISUM. N. F. (Br.)

ANISE Anis. [Anise Seed]

"Anise is the dried ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*). Anise contains not more than 3 per cent. of other fruits, seeds or foreign organic matter and yields not more than 1.5 per cent. of acid insoluble ash." *N. F.* "Anise Fruit is the dried ripe fruit of Pimpinella Anisum, *Linn.*" *Br.*

Anisi Fructus, *Br.;* Fructus (Semen) Anisi, s. Anisi vulgaris; Aniseed, Anny, Aneys, Annyle; Anis, Anis vert, Graines d'Anis, *Fr.;* Fructus Anisi, *P. G.;* Anissame, Anis, *G.;* Anice, Anace, Semi d'Aniso, *It.;* Anis (Fruto de), Simiente de Anis, *Sp.;* Anison, *Ar.*

Pimpinella Anisum is an annual plant, about a foot in height, with an erect, smooth and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, or undivided, linear. The flowers are small white, and in terminal compound unbels, destitute of involucres. The fruit is a mouse-shaped cremocarp.

The anise plant is a native of Egypt and the Levant, but has been introduced into Southern Europe and is cultivated in all warm climates, especially Germany, Russia, Italy, Spain, France, Turkey, India, Japan and Chili. It is also cultivated occasionally in the gardens of this country. The Spanish, or Alicante, anise is smaller than the German or French, and is usually preferred; the Russian fruit is very short. It is said also to be extensively cultivated in India and South America, although we are not aware that the product ever comes into American commerce. Over a million pounds of anise enter the United States annually, most of it coming from Malaga, Spain. Smaller quantities were imported from Barcelona and London. That from London represented the Russian variety.

It is one of the oldest aromatics, having been used by the ancient Egyptians, and is spoken of by Theophrastus and cultivated in the imperial German farms of Charlemagne. In 1305 Edward I granted a patent giving the right to levy tolls upon it at the Bridge of London for the purpose of repairing the bridge.

Description and Physical Properties.—"*Unground Anise.*—Cremocarp broadly oval, laterally compressed; 3 to 6 mm. long and 2 to 3 mm. wide; mericarps usually cohering and attached to a slender pedicel 2 to 12 mm. long; apex with a ring-like disc and two projecting, diverging styles; externally grayish or greenish-gray, seldom grayish-brown, slightly pubescent; each mericarp with 5 light-brown, filiform ridges. Odor and taste agreeable and aromatic.

"*Structure.*—Epidermal layer with numerous papillæ and short, one-celled, non-glandular hairs having very thick papillose walls; primary ribs each with a small vascular bundle, surrounded by a few fibers; from 15 to 45 oil tubes extending as a more or less interrupted circle in the tissues of the mesocarp on the dorsal side of each mericarp and 2 large oil tubes on the commissural side; inner epidermis of pericarp consisting of a layer of narrow, tangentially elongated thin-walled cells except near the middle line of the commissural side where the cells may have thick porous or reticulate walls and some adjacent cells in the mesocarp may be thick-walled and porous, resembling stone cells; the seed coat of one layer of cells with thickened, yellowish-brown, inner walls, closely unites with the epidermis of the pericarp except where separated by a large cavity along the commissural side; endosperm chiefly of polygonal, thick-walled cells filled with spherical or ellipsoidal aleurone grains.

"*Powdered Anise.*—Yellowish-brown; numerous irregular fragments of pericarp showing portions of the yellowish oil tubes; fragments with tracheæ and fibers of carpophore; cells of endosperm filled with aleurone grains, the latter about 0.006 mm. in diameter and usually enclosing a rosette aggregate of calcium oxalate about 0.004 mm. in diameter; non-glandular hairs 1-celled, 0.025 to 0.200 mm. long, either straight or curved and with numerous, slight, centrifugal projections on the outer surface.

"Heat 1 Gm. of anise with 10 cc. of potassium hydroxide T.S.; no mouse-like odor develops (absence of fruits of *Conium maculatum*)." *N. F.*

"Ovoid, somewhat compressed laterally; about five millimetres long and two millimetres broad. Mericarps usually united and attached to the pedicel. Rough from the presence of short, bristly hairs. Greenish-grey or greyish-brown; primary ridges pale, slender and entire. In transverse section, numerous vittæ in each mericarp; commissural surface of the endosperm not deeply grooved. Agreeably aromatic odor; taste aromatic and sweet. Ash not more than 11 per cent." *Br.*

Their odor and taste, which depend upon a peculiar volatile oil existing to the extent of from 1.5 to 3.5 per cent., are imparted sparingly to boiling water, but freely to alcohol. (See *Oleum Anisi.*) The endosperm of the fruit contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The fruits are sometimes adulterated with fine gravel and small fragments of an argillaceous earth which resembles them in color. This accounts for the fact that the amount of ash may run as high as 30 per cent., greatly exceeding the official requirements. Their aromatic qualities are occasionally impaired by a slight fermentation, which they are apt to undergo in the mass, when collected before maturity. Russian anise is sometimes admixed with as much as 30 per cent. of coriander. Anise is also contaminated with weed seeds and stems of the anise plant. Occasional shipments of anise are found adulterated with exhausted fruits.

The Italian anise not infrequently is admixed with from 2 to 10 per cent. or even 50 per cent. of the fruits of conium. A case of poisoning is on record from the accidental admixture of the fruits of *Conium maculatum,* which latter may be distinguished by their crenate or notched ridges and the absence of oil tubes; by their mericarps being smooth, grooved upon the face, and having crenate or notched ridges with wrinkles between them. The conium fruits are, moreover, broader in proportion to their length, and are generally separated into half fruits (or single mericarps), while those of anise are whole (double mericarps).

Star aniseed, the *Cardamomum Siberiense* or *Annis de Sibérie* of the seventeenth century and the *badiane* of the French writers, is the product of *Illicium verum* Hook. f., Gaertn., and is fully described under the heading *Illicium,* Part II. They contain about 4 per cent. of a volatile oil very closely resembling that of anise. There are no known chemical differences between these oils, although dealers distinguish them by their odor and taste.

Ruschenberger has shown that oil of anise has a remarkable power of masking the odor of potassium sulphide; a drop of the oil having entirely deprived of offensive odor a drachm of lard with which five grains of the sulphide had been incorporated. (*Am. J. M. S.,* N. S., xlviii, 419.)

Uses.—Anise is a grateful aromatic carminative and may be used in flatulent *colic.* The oil is usually preferred, in this country.

Dose, eight to fifteen grains (0.5–1.0 Gm.).

Off. Prep.—Aqua Anisi, *Br.;* Species Laxativæ, *N. F.;* Species Pectorales, *N. F.;* Tinctura Rhei Dulcis, *N. F.*

ANTHEMIDIS FLORES. Br.

CHAMOMILE FLOWERS [Chamomile, English Chamomile, Roman Chamomile]

"Chamomile Flowers are the expanded flowerheads of Anthemis nobilis, *Linn.,* collected from cultivated plants, and dried." *Br.*

Anthemis, *U. S. VIII;* Flores Chamomillæ Romanæ, Roman, Low, Garden, White or English Chamomile, Chamomile Flowers, Camil, Camovyne, Whig-plant; Camomille Romaine, *Fr.;* Flos Chamomillae, *P. G.;* Römische Kamille, *G.;* Camomilla Romana, Camomilla Ingleses, *It.;* Manzanilla (Flor de), Manzanilla Romana, *Sp.*

The term "Chamomile" has been applied to several aromatic plants and it is therefore important always to distinguish by adjectives which variety of chamomile is desired or, better yet, avoid the use of the English name altogether. In this country the only chamomile at present officially recognized is the so-called German chamomile (see *Matricaria*); in Europe the Roman chamomile seems to be more popular.

Several species of anthemis have been employed in medicine. (See below.)

Anthemis nobilis is an herbaceous plant with a perennial root. This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of *Roman chamomile.* The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upward at their extremities. The leaves are bipinnate, the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disk, and white rays. The involucre is of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like paleæ. The ray florets are numerous, narrow and terminated with three small teeth. The whole herb has a peculiar fragrant odor, and a bitter aromatic taste.

By cultivation the yellow disk florets are often converted into the white ray florets. Thus altered, the flowers are said to be *double,* while those which remain unchanged are called *single;* but, as the conversion may be more or less complete, it generally happens that with each of the varieties there are intermingled some flowers of the other kind, or in different stages of the change. The double flowers are generally preferred; though, as the sensible properties are found in the greatest degree in the disc florets, the single flower heads are the more powerful. It is rather, however, in aromatic flavor than in bitterness that the radical florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white color, and are less efficient. The flowers which are largest, most double, and whitest should be preferred.

They are officially described as: "Flowerheads hemispherical, from about twelve to twenty millimetres in diameter, white or pale buff in color. Involucre composed of several rows of oblong bracts with membranous margins; receptacle solid, conical, and densely covered with concave, blunt, narrow, scaly bracts; florets mostly ligulate and white, the ligula possessing four veins and terminating in three teeth. Strong aromatic odor; taste bitter." *Br.*

C. W. Ballard states that this drug is offered as "chamomile" and "Spanish chamomile," and that the U. S. P. IX gives "chamomile" and "wild chamomile" as synonyms of matricaria. He tabulates the chief differences and similarities in wild anthemis, cultivated anthemis and matricaria. (See *J. A. Ph. A.,* 1918, vii, 952.)

The seeds yield by expression a fixed oil, which is said to be applied in Europe to various economical uses.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The medicine, as found in commerce, consists chiefly of the double flowers, and is imported from Germany and England. From the former country the flowers of *Matricaria Chamomilla* are also occasionally imported, under the name of chamomile. (See *Matricaria.*) In Europe the flowers of *A. arvensis* L. (*corn chamomile*) are sometimes substituted for the official drug.

A. Tinctoria L. has been used as a vermifuge in Europe.

The chief adulterant at present for Roman chamomile is the flower heads of *Anthemis Cotula* L. (*Dog chamomile, Mayweed*), an annual, glabrous herb with a disagreeable odor, indigenous to Europe but widely naturalized in the United States. These flower-heads differ from the genuine article in possessing a more elongated-conical receptacle, neutral, ligulate floret, fimbriate, obovate bracts and rough, 10-ribbed achenes. It was formerly recognized by the U. S. (1870) under the title *Cotula.*

Properties.—Chamomile flowers, as usually found in commerce, are large, almost spherical, of a dull white color, a fragrant odor, and a warmish, bitter, aromatic taste. When fresh, their odor is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamæmelum* (χαμαί, on the ground, and μῆλον, an apple); and it is somewhat singular that the Spanish name *manzanilla* (a little apple) has a similar derivation. The flowers impart their odor and taste to water and alcohol, the former of which, at the boiling temperature, extracts only one-fourth of their weight.

The sensible, and probably the medicinal properties are due to a volatile oil, which when fresh is blue in color but as commonly seen is greenish or even brown. The investigations of several chemists made in 1878–1879, in Fittig's laboratory at Strassburg, have shown the *oil of chamomile* to contain the following constituents: a fraction distilling at 147° to 148° C. consisting of isobutylic esters and hydrocarbons; *isobutyl angelicate* at 177° C.; *isoamyl angelicate* at 200° to 201° C.; *isoamyl tiglinate* at 204° to 205° C. (both of these esters answering to the formula $C_5H_{11},C_5H_7O_2$). In the residual portion, hexylic alcohol, C_6H_{13}, OH, and an alcohol of the formula $C_{10}H_{16}O$ isomeric with camphor, to which the name of *anthemol* has been given (see *Chem. Cb.*, 1903 (1), 1226), are met with, both probably occurring in the form of esters. By decomposing the angelicates and the tiglinate with potassium hydroxide, angelic acid, $C_5H_8O_2$, and *tiglic acid* (or *methyl-crotonic*), isomeric with the former, are obtained to the extent of about 30 or more per cent. of the crude oil. In the oil examined by Fittig, angelic acid prevailed; from another specimen E. Schmidt (1879) obtained but very little of it, tiglic acid prevailing. Naudin (*Bull. Soc. Chim.*, 1884, 41, 483) extracted also a solid paraffin, $C_{18}H_{36}$, to which the name of *anthemene* was given; Klopp obtained another body, *anthesterin,* from chamomile. (*P. J.*, 1903, 458.) Umney states that pure oil of chamomile has the sp. gr. 0.905 to 0.912 at 15° C. (*P. J.*, 1895, p. 949).

The oil from *Anthemis Cotula* closely resembles that from *A. nobilis,* see *A. J. P.*, 1885, pp. 376, 381. E. Amerman (*A. J. P.*, 1889, p. 69) obtained a wax which was nearly white, bitter, and crystalline, melting at about 130° C., and a crystalline substance distinctly acid and of a glucosidal nature. There was no evidence of the presence of an alkaloid. (See *Oleum Anthemidis.*)

Uses.—Chamomile is an aromatic bitter, in small doses acceptable and corroborant to the stomach, in large doses capable of acting as an emetic. In cold infusion it is often advantageously used in cases of *enfeebled digestion* in convalescence of *general debility,* with languid appetite, which often attends convalescence from infectious fevers. The flowers are sometimes applied externally in the form of fomentation, in cases of irritation or inflammation of the abdominal viscera, and as a gentle incitant in flabby, ill-conditioned *ulcers.* The infusion is usually preferred. The decoction or extract cannot exert the full influence of the medicine, as the volatile oil is driven off.

Dose, from half a drachm to a drachm (2.0–3.9 Gm.).

ANTIMONII ET POTASSII TARTRAS.
U. S. (Br.)

ANTIMONY AND POTASSIUM TARTRATE Antim. et Pot. Tart. [Tartar Emetic; Tartarated Antimony; Antimonyl Potassium Tartrate]

"Antimony and Potassium Tartrate contains not less than 98.5 per cent. of $K(SbO)C_4H_4O_6.\frac{1}{2}H_2O$." *U. S.*

"Tartarated Antimony may be obtained by setting aside a mixture of antimonious oxide and acid potassium tartrate, made into a paste with a little water, until combination has taken place, and then purifying by crystallisation from water. Contains not less than 99 per cent. of antimonium potasso-tartrate, $(KSbOC_4H_4O_6)_2,H_2O$." *Br.*

Antimonium Tartaratum, *Br.;* Tartrated Antimony; Emetic Tartar; Potassium antimonyl tartrate; Antimonium Tartarizatum; Potassio-Tartrate of Antimony; Antimonii Potassio-Tartras, Tartarus Emeticus; Tartras Stibii et Kalii; Stibio-Kali Tartaricum, *Fr. Cod.;* Antimoniotartrate Acide de Potassium; Tartrate d'Antimoine et de Potasse, Emétique, Tartre stibié, *Fr.;* Tartarus Stibiatus, *P. G.;* Brechweinstein, *G.;* Tartrato di antimonico e di potassio, *It.;* Tartrato antimonico potasico, *Sp.*

A process for Tartar Emetic not now being given in the U. S. Pharmacopœia, that of 1870 follows: "Take of Oxide of Antimony, in very fine powder, *two troyounces;* Bitartrate of Potassium, in very fine powder, *two troyounces and a half;* Distilled Water, *eighteen fluid-*

ounces. To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stoppered bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U. S.*, 1870.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; it is not material what plan is adopted, provided the crystals of the antimonial salt be carefully purified. For other methods and comments on its preparation see *U. S. D.*, 17th edition, p. 175 and *U. S. D.*, 20th edition, p. 149.

The theoretical structure of this salt is a matter of some difference of opinion; some regard it as a derivative of the neutral potassium tartrate in which one of the elements of potassium is replaced by the basic radical SbO. Fargher and Gray (*J. P. Ex. T.*, 1921, xviii, p. 341) favor the view, however, that it is a derivative of ortho-antimonious acid $Sb(OH)_3$, in which two of the hydroxyl groups are replaced by the divalent tartaric acid and the remaining hydrogen atom by potassium.

Description and Physical Properties.—"Colorless, odorless, transparent crystals of the rhombic system, or a white granular powder. The crystals effloresce upon exposure to air. One Gm. of Antimony and Potassium Tartrate is soluble in 12 cc. of water and in 15 cc. of glycerin, at 25° C. One Gm. is soluble in 3 cc. of boiling water. It is insoluble in alcohol.

"An aqueous solution of Antimony and Potassium Tartrate (1 in 20) is slightly acid to litmus paper. When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue. This residue has an alkaline reaction, and when a small fragment of it is held in a non-luminous flame, a violet tint is produced. In an aqueous solution of Antimony and Potassium Tartrate (1 in 20), acidulated with hydrochloric acid, hydrogen sulphide T.S. produces an orange-red precipitate, which is soluble in ammonium sulphide T.S. or potassium hydroxide T.S.

"A 10 cc. portion of an aqueous solution of the salt (1 in 100) acidulated with acetic acid does not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (*iron*). Dissolve 0.1 Gm. of Antimony and Potassium Tartrate in 5 cc. of concentrated hydrochloric acid: the solution meets the requirements of Bettendorf's Test for *arsenic*.

"**Assay.**—Dissolve about 0.5 Gm. of Antimony and Potassium Tartrate, accurately weighed, in 30 cc. of distilled water, add 25 cc. of a cold, saturated solution of sodium bicarbonate and a few drops of starch T.S., and immediately titrate with tenth-normal iodine to the production of a permanent blue color. Each cc. of tenth-normal iodine corresponds to 0.01662 Gm. of $K(SbO)C_4H_4O_6 . \frac{1}{2} H_2O$.

"Preserve in well-closed containers." *U. S.*

"Soluble in 17 parts of *water*, forming a slightly acid solution; almost insoluble in *alcohol* (90 per cent.), moderately soluble in weak alcoholic liquids. Taste sweet and metallic. Precipitated from its solutions by *solution of tannic acid.* Yields the *reactions* characteristic of antimony, of potassium, and of tartrates. The solution obtained by dissolving 0.5 gramme in 25 millilitres of *water*, and adding 5 grammes of *sodium potassium tartrate* and 1.5 grammes of *sodium bicarbonate*, discharges the color of not less than 29.8 or more than 30.2 millilitres of *N/10 solution of iodine.* Yields no characteristic *reactions* for lead, copper, iron, sodium, ammonium, chlorides, or sulphates. Does not effervesce with an aqueous solution of *sodium bicarbonate* (absence of acid potassium tartrate)." *Br.*

It is incompatibile with acids, hydroxides, carbonates, some of the earths and metals, calcium chloride, and lead acetate and subacetate. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, etc.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent. Hydrochloric and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of antimony trichloride or subsulphate, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of acid. When solution of potassium hydroxide is added to a concentrated solution, it produces at first no effect, and then a precipitate of trioxide, which is redissolved on the continued addition of the alkali. Lime water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed calcium and antimony tartrates. Potassium carbonate affects still weaker solutions, throwing down a white precipitate of trioxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure trioxide. To these reagents may be added infusion of galls, which when fresh and strong, causes a dirty-yellowish-white precipitate of antimony tannate.

Uses.—When tartar emetic is given in minute doses (gr. 1/12, or 0.005 Gm.) to a healthy man it produces only a slight lessening of the force of the pulse and a tendency to increased secretion from the skin. After somewhat larger amounts these symptoms are more pronounced, and have nausea added to them. If a grain be ingested, the nausea and vomiting will be severe and persistent, and accompanied by severe purging and marked prostration, both of the circulation and of the muscular strength. In the lower animals antimony causes symptoms similar to those which it produces in man. It has been experimentally proved that the fall of the arterial pressure is produced, at least in part, by a direct action upon the heart. The loss of muscular power, of reflex activity, and of sensibility is believed to be due to depression of the spinal centers, and the disturbance of respiration to a direct influence upon the nerve-centers which preside over that function. The purging and vomiting are connected with an effort at elimination, the poison escaping through the gastro-intestinal mucous membrane, as well as through the kidneys. After death from antimony, fatty degeneration of the liver, kidneys, and other organs has been found, indicating that the poison has a powerful influence upon nutrition. It is evident that in small doses tartar emetic is powerfully depressant to the circulation and stimulant to the secretion of the skin. Weiss and Hatcher (*J. Ex. M.*, 1923, xxxvii, 97) conclude that the emesis after oral exhibition of antimony is due chiefly to irritation of the stomach; the nausea following its intravenous injection they believe is a reflex from the heart.

Tartar emetic is employed occasionally as a diaphoretic and expectorant, but has been largely supplanted by other less dangerous remedies as a circulatory depressant. In the first stage of a *bronchitis* in a sthenic subject it is often of great service. Its emetic action is very certain, powerful, prolonged, but accompanied with much depression. It is very badly borne by children. Tartar emetic is occasionally used as a counter-irritant in the form of an ointment or plaster, whose application produces sooner or later a burning sensation accompanied by a very painful pustular eruption with ulcerations.

Like its related element arsenic, antimony is poisonous to various of the lower forms of life, notably protozoa. Within recent years it has achieved a considerable importance in the treatment of various tropical infections. Its use in these conditions dates from the discovery of Plimmer and Thompson in 1908 (*Proc. Roy. Soc.*, Series B, lxxx, 1) of its effect in *trypanosomiasis*. Although Voegtlin and Smith (*J. P. Ex. T.*, 1920, xv, p. 453), in studies on rats find that the ratio between the toxic and curative dose of antimony tartrate is narrower than that of arsphenamine, it has been found to be clinically useful in the treatment of human infections by trypanosomes. McWalter (*B. M. J.*, Oct. 10, 1914) has also found it exercises beneficial effects in *syphilis* although by itself not completely curative. The most favorable results have been obtained in *schistosomiasis* (*bilharziasis*) (see Christopherson, *L. L.*, 1919, ii, 1021) and *kala-azar* (see Kerr, *L. L.*, July 13, 1918, and Rogers, *Indian Med. Gaz.*, 1917, lii, p. 265). It is also recommended by Rogers (*B. M. J.*, Jan. 6, 1917) for the destruction of the crescents in the treatment of *tertian malarial fever*. It has been recommended by MacFie (*Annals of Tropical Med. and Parasitology*, 1920, xiv, p. 145) in infestation by the *Guinea-worm*. It is also employed in the treatment of *granuloma inguinalis* (see Lynch, *J. A. M. A.*, 1921, lxxvii, 925).

For the destruction of various blood parasites antimony must be given intravenously. Various preparations have been employed but it is not yet demonstrated that any of them are superior in value to the tartar emetic. For this purpose it is used in doses of from one-half to two grains (0.03 to 0.12 Gm.) every alternate day. Klemperer (*D. M. W.*, 1911) also reports favorable results from the use of tartar emetic in *pernicious anemia*. He gave hypodermically one sixty-fourth of a grain (1 mgm.) daily. The drug has also been employed in veterinary medicine as a vermifuge.

Poisoning.—Symptoms of acute poisoning by the drug are an austere metallic taste, excessive nausea, copious vomiting, frequent hiccough, burning pain in the stomach, colic, frequent stools and tenesmus, fainting, rapid and feeble pulse, coldness of the skin, and even of the internal organs, difficult and irregular respiration, cutaneous anesthesia, convulsive movements, painful cramps in the legs, prostration, and death. Ten grains (0.65 Gm.) is the smallest dose reported to have proved fatal. In rare cases vomiting and purging do not take place, and when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial.

When given in repeated small doses, tartar emetic produces both in man and in the lower animals a chronic poisoning, in which the chief symptoms are nausea, vomiting, watery purging, often followed by constipation, failing circulation, and a general asthenia, deepening into death from exhaustion. After death from antimonial preparations, decided evidences of gastro-intestinal irritation are apt to be present, but they have been in some cases wanting. The blood is often markedly fluid. Intense venous congestion, especially of the lungs, is usually present, and in some cases pulmonary apoplexy, atelectasis, or other structural lesion of the lungs has been found. A wide-spread fatty degeneration has been noted as constant in chronic poisoning in animals, and probably occurs also in man.

The treatment of tartar emetic poisoning consists, first, in washing out the stomach with a solution of tannic acid; second, in meeting the symptoms as they arise, especially by the use of opiates, which should be administered hypodermically and by rectal suppositories; external warmth, stimulants, etc., should be used *pro re nata*. Rosenthal and Severn (*A. E. P. P.*, 1912, lxvii, p. 275) assert that potassium hexatantalate is a valuable antidote in poisoning by antimony, being capable of following the drug after its absorption and producing a non-toxic compound in the system. In all cases of suspected poisoning, the vomit, the passages from the bowels, and especially the urine should be saved. The metal has been found in all the tissues of the body, but in the experiments of B. W. Richardson it was most abundant in the liver.

Dose, as a diaphoretic or expectorant, one-thirtieth to one-tenth of a grain (0.002–0.006 Gm.); as an emetic, half a grain (0.032 Gm.).

ANTIMONII OXIDUM. N. F., Br.

ANTIMONY OXIDE Antim. Oxid.

"Antimony Oxide contains not less than 97 per cent. of antimonous oxide (Sb_2O_3 = 288.4)." *N. F.*

"Antimonious Oxide, Sb_2O_3, may be obtained by pouring solution of antimonious chloride into water, and decomposing the precipitated antimony oxychloride with sodium carbonate." *Br.*

Antimonious Oxide; Antimonious Anhydride; Antimony Trioxide; Oxide of Antimony; Stibium Oxydatum, Oxydum Antimonicum s. Stibicum; Oxyde d'Antimoine, *Fr.;* Antimonoxyd, *G.;* Oxido de antimonio, *Sp.*

This compound is no longer official in the U. S. Pharmacopœia, but has been introduced into the N. F. The process of the U. S. P. 1870, with comments will be found in the *U. S. D.,* 20th edition, p. 151.

Description and Physical Properties.—"Antimony Oxide is a white or grayish-white powder, odorless and tasteless, It is insoluble in water, alcohol or nitric acid; readily dissolved by hydrochloric acid without effervescence, and also by a warm aqueous solution of tartaric acid or by a boiling aqueous solution of potassium bitartrate. When heated Antimony Oxide turns yellow but it again becomes white on cooling. At a dull red heat it fuses to a yellowish liquid and at a higher temperature it volatilizes.

"Dissolve Antimony Oxide in a slight excess of hydrochloric acid and dilute the solution with a large volume of distilled water; a white precipitate is produced which is changed to orange by hydrogen sulphide.

"A solution of 0.1 Gm. of the Oxide in 3 cc. of hydrochloric acid and 5 cc. of distilled water is not rendered turbid at once by a few drops of barium chloride T.S. (*sulphate*). A solution of 0.1 Gm. of the Oxide in 10 cc. of distilled water and 1 Gm. of tartaric acid does not become more than slightly opalescent on the addition of 0.2 cc. of nitric acid and 0.2 cc. of silver nitrate T.S. (*chloride*). Dissolve 0.5 Gm. of the Oxide in 10 cc. of hydrochloric acid, dilute the solution with distilled water until it begins to become permanently turbid and then precipitate with hydrogen sulphide. This precipitate when thoroughly washed with distilled water dissolves in ammonium sulphide T.S. or sodium sulphide T.S., without leaving a black insoluble residue (*copper* or *lead*). A solution of 0.1 Gm. of Antimony Oxide in 5 cc. of hydrochloric acid does not respond to Bettendorf's test for arsenic.

"**Assay.**—Dissolve about 0.2 Gm., of Antimony Oxide, accurately weighed, by warming it in a solution of 1 Gm. of tartaric acid in 10 cc. of distilled water (adding a few drops of hydrochloric acid to aid the solution). Nearly neutralize the solution with sodium carbonate, then add 40 cc. of a cold saturated solution of sodium bicarbonate and titrate at once with tenth-normal iodine, using starch as indicator. Each cc. of tenth-normal iodine corresponds to 0.00721 Gm. of Sb_2O_3. One Gm. of Antimony Oxide corresponds to not less than 134.5 cc. of tenth-normal iodine." *N. F.*

"A greyish-white powder, fusible at a low red heat. Insoluble in *water.* Readily soluble in *hydrochloric* acid, the solution yielding the *reactions* characteristic of antimony. The solution obtained by dissolving 0.25 gramme in *diluted hydrochloric acid,* adding 5 grammes of *sodium potassium tartrate* and then a slight excess of *sodium bicarbonate,* discharges the color of 34.5 millilitres of *N/10 solution of iodine.* Yields no characteristic *reactions* for lead, copper, arsenium, calcium, sodium, or potassium, not more than slight *reactions* for iron, and not more than the slightest *reactions* for chlorides or sulphates. Dissolves entirely when boiled with an excess of an aqueous solution of *acid potassium tartrate.*" *Br.*

It is frequently impure from the presence of the before-mentioned antimony antimonate, in which case it is not *entirely* soluble in hydrochloric acid. If it contain oxychloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by silver nitrate. When antimony antimonate is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in hydrochloric acid.

Uses.—This oxide, which must not be confounded with the powder of Algaroth or antimony oxychloride (see Part II), has the general therapeutic properties of the antimonials. It is not suited for administration by the mouth because of the uncertainty of its effects by this channel, on account of the variations in acidity of the stomach.

Antimony trioxide has been recently recommended in the place of tartar emetic for the treatment of protozoal infections. It has the advantage over tartar emetic that being less locally irritant it may be administered subcutaneously or intramuscularly.

Dose, one to two grains (0.06–0.12 Gm.).

Off. Prep.—Pulvis Antimonialis, *Br., N. F.*

ANTIMONIUM

ANTIMONY

Stibium, *Lat.;* Antimoine, *Fr.;* Antimon, Spiessglanz Metall, *G.;* Antimonia, *It.;* Antimonio, *Sp.*

Metallic antimony, sometimes called *regulus of antimony,* is not official in the British or United States Pharmacopœia, but, as it enters into the composition of a number of important pharmaceutical preparations, we have thought it proper to notice it under a distinct head.

Antimony exists in nature: (1) uncombined; (2) as an oxide; (3) as antimonous sulphide (tersulphide), and (4) as an oxysulphide. It is found in France, Japan, and Hungary, but most largely in China which it is stated yields 85 per cent. of the world's production, and has been discovered also in Ontario, Alaska, and in smaller amounts in California and Nevada.

Extraction.—Much of the antimony of commerce is extracted from the native sulphide called *stibnite* (see *Antimony sulphide,* Part II). The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace, where it is subjected to a gentle heat, being constantly stirred with an iron rake. This process of roasting is known to be completed when the matter is brought to the state of a dull, grayish-white powder called *antimony ash.* By this treatment the antimony is partly trioxidized, and partly converted into antimonous acid, while nearly all the sulphur is dissipated in the form of sulphurous acid gas; a portion of trisulphide, however, remains undecomposed. The matter is then mixed with charcoal impregnated with a concentrated solution of sodium carbonate, and the mixture heated in crucibles, in a melting-furnace. The charcoal reduces the antimony trioxide, while the alkali unites with the undecomposed trisulphide, and forms melted scoriæ, which cover the reduced metal and diminish its loss from volatilization. Antimony is also frequently obtained by the reduction by iron of the native sulphide. The reduction of the antimony sulphide by iron takes place at a red heat, but as iron sulphide needs a higher temperature for its fusion, and its specific gravity is not much less than that of the metallic antimony, the mass must be heated to a white heat to effect a perfect separation, and this occasions a loss of antimony. In order to avoid this, sodium sulphide is added in practice, which unites with the iron sulphide to form a more fusible and lighter slag of double sodium and iron sulphide. For 100 parts of antimony sulphide are taken 42 parts of iron, 10 parts of anhydrous sodium sulphate, and 2½ to 3½ parts of carbon.

The purest commercial antimony is not entirely free from foreign metals, chiefly iron, lead, and arsenic. Lefort purifies it for the purposes of pharmacy by gradually adding twenty-five parts of the metal, in fine powder, to fifty parts of nitric acid, by the action of which the antimony is precipitated as antimonous acid, while the foreign metals remain in solution. The precipitate is then thoroughly washed with water containing a hundredth part of nitric acid, drained completely, mixed with three or four parts of powdered sugar, and reduced to the metallic state by being heated to redness in a Hessian crucible. Antimony is imported into the United States in the form of antimony sulphide, as antimony regulus or metal, and most largely as *"hard lead"* or *antimonial lead* obtained as a by-product in smelting lead or silver ores which contain from 3 to 10 per cent. of antimony.

Properties.—The time of the discovery of antimony is not known, but Basil Valentine was the first to describe the method of obtaining it, in his work entitled *"Currus Triumphalis Antimonii,"* published towards the end of the fifteen century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, of a silver-white color when pure, but bluish white as it occurs in commerce. Its atomic weight is 120.2, Symbol Sb, sp. gr. 6.7, and fusing point 630° C. On cooling, after fusion, antimony assumes an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated, it burns with the emission of white vapors, consisting of teroxide, formerly called *argentine flowers of antimony.* A small portion being fused and then thrown upon a flat surface divides into numerous globules, which burn rapidly as they move along. It forms three combinations with oxygen, *antimony trioxide* (antimonous oxide), Sb_2O_3, *antimony tetroxide,* Sb_2O_4 (by some considered to be an antimonate of the radical *antimonyl,* $SbO.SbO_3$), and *antimony pentoxide* (antimonic oxide), Sb_2O_5. The first of these unites with water to form antimonous acid, the salts of which are called *antimonites,* the third unites with water to form antimonic acid, the salts of which are called *antimonates.* The trioxide was noticed under the head of *Antimonii Oxidum.* The tetroxide is a white powder, yellowish when hot, and difficultly soluble in acids. It forms when either of the other two oxides is strongly heated in air. *Antimony ash,* described above, is also an impure tetroxide. *Antimonic acid* is a lemon-colored powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of the acid by a heat not exceeding 315.5° C. When exposed to a red heat, it parts with oxygen, and is converted into the *antimony tetroxide* just described. This, though medicinally inert, frequently was found in former days in a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis.*)

The activity of antimonials is proportional not merely to their solubility in the gastric juices but, according to the researches of Brunner (*A. E. P. P.*, 1912, lxviii, p. 186), especially depends upon whether the metal is in the trivalent or pentavalent condition, the latter being comparatively innocuous.

ANTIMONIUM SULPHURATUM. Br.

SULPHURATED ANTIMONY [Kermes Mineral]

"Sulphurated Antimony is a mixture containing antimony sulphides and oxides, and sulphur." *Br.*

Antimonium Oxysulphuratum, Antimonii Oxysulphuretum, Antimonii Sulphuretum Aureum; Precipitated Sulphide of Antimony; Antimony Pentasulphide; Sulphur Auratum Antimonii; Golden Sulphuret of Antimony, Golden Sulphur; Pentasulfure d'Antimoine, *Fr. Cod.;* Soufre doré d'Antimoine, *Fr.;* Stibium Sulfuratum Aurantiacum, *P. G.;* Goldschwefel, Gefälltes Schwefelantimon, *G.;* Kermes minerale, *It.;* Quermes mineral, Oxisulfuro de antimonio hidratado, *Sp.*

Sulphurated antimony was not introduced into the U. S. P. or N. F.

The process of the British Pharmacopœia (1914) is as follows: "Antimonious sulphide ('black antimony') of commerce, 200 grammes; Sublimed Sulphur, 200 grammes; Caustic soda of commerce, 100 grammes; Diluted Sulphuric Acid, Distilled Water, of each a sufficient quantity. Dissolve the caustic soda in two thousand millilitres of the Distilled Water; with this solution mix the antimonious sulphide and the Sublimed Sulphur; boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same volume; then, while the mixture is still hot, add three thousand six hundred millilitres of boiling Distilled Water; strain the product through calico; before the strained liquid cools add to it by degrees Diluted Sulphuric acid till the latter is in slight excess; collect the precipitate on a calico filter; wash with Distilled Water till the washings are free from sulphates; dry at a temperature not exceeding 100° C." *Br.*

For description of the native antimonous sulphide (black antimony) see *Antimony Sulphide,* Part II. When this is boiled with sodium hydroxide there is formed *sodium dihydrogen orthoantimonite* and *sodium sulphantimonite* according to the following reaction:

$$Sb_2S_3 + 4NaOH = NaH_2SbO_3 + Na_3SbS_3 + H_2O.$$

This was the substance recognized by the U. S. 1890 as *Antimonium Sulphuratum.* In the process of the British Pharmacopœia a part of the free sulphur combines with the sodium hydroxide to form sodium sulphide and the latter reacts with the antimony sulphide to form *sodium sulphantimonate,* sometimes called *Schlippe's salt.* The latter reaction may be represented thus:

$$Sb_2S_3 + 3Na_2S + S_2 = 2Na_2SbS_4.$$

The sodium sulphantimonate when decomposed by a mineral acid yields *antimony pentasulphide* according to the reaction:

$$2(SbS_4Na_3 + 9H_2O) + 3H_2SO_4 = 3Na_2SO_4 + Sb_2S_5 + 3H_2S + 18H_2O.$$

Ten parts of Schlippe's salt yield in theory 4.17 parts of antimony pentasulphide. In actual practice, however, there is present variable amounts of antimony oxides and free sulphur. A purer form of antimony pentasulphide may be obtained, according to the suggestion of E. G. Eberhardt, by treating the native sulphide with hydrochloric acid and precipitating the solution with hydrogen sulphide. The objection that arsenic might be found in the product was met by an examination which showed that traces of arsenic present were not more than when the then official process had been employed. *A. J. J.,* 1886, p. 229.) The color of sulphurated antimony or Kermes mineral is influenced by porphyrization, with the admixture of a little sugar or gum; if hastily porphyrized, the mixture has a violet tint; if carefully and slowly, it has a russet color.

Properties.—"An orange-red powder, readily dissolved by hot *hydrochloric acid,* with evolution of hydrogen sulphide and separation of sulphur. 1 gramme digested with 20 millilitres of hot *water* yields a filtrate which, after acidification with *diluted nitric acid,* becomes not more than slightly cloudy on the addition of *solution of barium chloride* (limit of sulphates). *Arsenic limit* 1000 parts per million. 3 grammes moistened with *diluted nitric acid,* warmed with successive portions of *fuming nitric acid* until red fumes cease to be evolved, and then dried and carefully heated to redness, leave a whitish residue weighing not less than 1.6 or more than 1.8 grammes." *Br.*

The former U. S. preparation was "an amorphous, reddish-brown powder, becoming lighter in color on exposure to light, and having neither odor nor taste. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide.

"When heated in a dry test-tube, it emits moisture and leaves a black residue.

"If 1 Gm. of Sulphurated Antominy be gently heated with 10 cc. of hydrochloric acid, it should dissolve, with the exception of a slight residue, which, when washed and dried, should burn on the application of a flame with the characteristic odor of sulphur, leaving not more than a scanty ash. The acid solution, completely deprived of hydrogen sulphide by boiling yields, when added to water, a white precipitate, which, after being washed and dried should weigh not less than 85 per cent. of the original weight of the sulphide. The liquid filtered from this precipitate yields an orange-red precipitate with hydrogen sulphide T.S.

"If 1 Gm. of Sulphurated Antimony be shaken with 20 cc. of hot water, the filtrate should be neutral to test paper, should not be rendered more than slightly opalescent by barium chloride T.S. (limit of *sulphate*), or silver nitrate T.S. (limit of *chloride*), and should not be affected by ammonium oxalate T.S. (absence of *calcium*)." *U. S.,* 1890.

Uses.—Precipitated antimony sulphide (*sulphurated antimony*) is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, and is very little used. In combination with calomel and guaiac (*Plummer's pill*), it was formerly employed in *secondary syphilis* and *cutaneous eruptions.* (See *Pilulæ Antimonii Compositæ,* U. S. P. 1890.) During its use the patient should abstain from acidulous drinks.

Dose, as an alterative, from one to two grains (0.065–0.13 Gm.).

Off. Prep.—Pilulæ Hydrargyri Subschloridi Composita, *Br.*

ANTIPYRINA. U. S. (Br.)

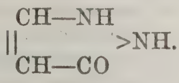
ANTIPYRINE Antipyr. [Phenazone]

"Phenyldimethyl pyrazolon [$C_3HON_2(CH_3)_2.C_6H_5$]." *U. S.* "Phenazone, or phenyl-dimethyl-iso-pyrazolone, $C_{11}H_{12}N_2O$, may be obtained from phenyl-hydrazine by interaction with aceto-acetic ether, and the subsequent interaction of the resulting phenyl-methyl-iso-pyrazolone with methyl iodide." *Br.*

Phenazonum, *Br.;* Phenazone; Phenyldimethylisopyrazolone, Methozine, Dehydrodimethylphenylpyrazine; Analgésine, Parodyne, Anodynine, *Fr.;* Pyrazolonum phenyldimethylicum, *P. G.;* Phenyldimethylpyrazolon, Antipyrin, *G.;* Antipirina, *It., Sp.*

Dose, three to fifteen grains (0.2–1.0 Gm.).

Preparation.—This compound is one of the first important synthetical remedies introduced into medicine; it is now generally conceded to be a derivative of *pyrrol,* C_4H_5N, a base found in coal tar and in bone oil. From this base is derived *pyrazole* (see Part II) and from the latter *pyrazolon.* This in turn by molecular rearrangement yields *isopyrazolon,*



$$\begin{array}{l} CH—NH \\ || \qquad\qquad >NH. \\ CH—CO \end{array}$$

Phenyldimethylisopyrazolon is a substitution product from this. Practically it is made by Knorr's patented process of acting upon phenylhydrazine, $C_6H_5.NH.NH_2$, with ethyl acetoacetate, $(CH_3.CO)CH_2.CO.C_2H_5$, when phenylmethyl-pyrazolon is formed. This is then methylated by treatment with methyl iodide, when the hydriodide of the finished base results. It has also been made by condensing molecular proportions of ethyl aceto-acetate and methylphenyl-hydrazine. Another process consists in combining phenyl-hydrazine with β-chlorozopropionic acid to form phenyl-dihydro-pyrazolone, which is later oxidized to phenyl pyrazolone, which upon methylation is converted into antipyrine. Another reaction product—viz., that of halogen butyrate acting upon phenyl-hydrazine with the subsequent oxidation and methylation of the compound so obtained, which is also a phenyldimethylpyrazolon—is only an isomer of true antipyrine; not identical with it.

Description and Physical Properties.—"Colorless crystals, or a white, crystalline powder. It is odorless, and has a slightly bitter taste. One Gm. of Antipyrine is soluble in less than 1 cc. of water, 1.3 cc. of alcohol, 1 cc. of chloroform, and in 43 cc. of ether, at 25° C.

"Antipyrine melts between 111° and 113° C. The addition of tannic acid T.S. to an aqueous solution of Antipyrine produces an abundant white precipitate. Mix 0.1 Gm. of sodium nitrite and 12 cc. of an aqueous solution of Antipyrine (1 in 100): a nearly colorless liquid is obtained, which, upon the addition of 1 cc. of diluted sulphuric acid, develops a deep green color. One drop of ferric chloride T.S. added to 2 cc. of a dilute aqueous solution of Antipyrine (1 in 1000) produces a deep red color, which, upon the addition of 10 drops of sulphuric acid, is changed to light yellow.

"Its aqueous solution (1 in 20) is neutral to litmus paper. Ash: not more than 0.1 per cent. Antipyrine is completely soluble in its own weight of cold distilled water, the solution being colorless or not more than slightly yellow when viewed transversely in a tube having a diameter of about 20 mm. An aqueous solution of Antipyrine meets the requirements of the test for *heavy metals.*" *U. S.*

It is described in the British Pharmacopœia as "small, colorless, scaly crystals. No odor; taste bitter. Soluble in 1.2 parts of *water,* in 1.3 parts of *alcohol* (90 per cent.), and in 1.3 parts of *chloroform.* Melting point from 111° to 113° C. Aqueous solution neutral to *litmus.* An aqueous solution (1 in 100) responds to the following tests:—Mixed with an equal volume of *nitric acid* it assumes a yellow color passing to crimson on warming; 2 millilitres are colored green by 2 drops of *fuming nitric acid,* and the color is changed to red by boiling with an additional 3 or 4 drops of the *fuming nitric acid;* 12 millilitres remain nearly colorless on the addition of 0.1 gramme of *sodium nitrite,* but turn deep green on the further addition of 1 millilitre of *diluted sulphuric acid;* 1 millilitre, diluted with 9 millilitres of *water,* is colored deep red by *T. Sol. of ferric chloride,* the color being nearly discharged by excess of *diluted sulphuric acid.* An aqueous solution (1 to 20) gives with *T. Sol. of mercuric chloride* a white precipitate which disappears on boiling, but reappears on cooling. Aqueous solution not affected by *hydrogen sulphide.* No appreciable ash." *Br.*

Antipyrine may be quantitatively determined by taking advantage of its power, of combining with iodine, and several methods have been devised for its estimation. (*J. P. C.,* 1917, xv, 93–337.)

Antipyrine is incompatible with hexamethyleneamine, formaldehyde, nitrites and ferric salts, the latter producing marked color reactions. It forms eutectic mixtures which liquefy when it is triturated with many other organic compounds like salol, etc.

Uses.—Locally antipyrine exercises an anesthetic effect upon the nerve endings and causes constriction of the superficial blood vessels. When taken into the stomach it is absorbed rapidly and eliminated unchanged chiefly through the kidneys, although it has been demonstrated in various other secretions. In appropriate dose it causes in the lower animals increased activity of reflexes through an action upon the spinal cord, a rise in the blood pressure through an influence upon the cardiac and vascular muscles, and a slight stimulation of the respiratory center. These actions, however, are of little importance from a standpoint of the clinical use of the drug. The medicinal value of antipyrine, aside from its local uses, is based on its effects on the pain-perceiving mechanism and upon the thermoregulator apparatus, similar to that described under acetanilid. As far as at present known, these effects are precisely analogous to that of the anilin derivatives, but it is somewhat more prompt in its action and some believe also more prone to produce collapse than either acetanilid or acetphenetidin.

Antipyrine is useful in medicine most largely for the relief of pain, especially of nervous origin, as *neuralgias, migraine,* crises of *locomotor ataxia,* and similar conditions. In so-called *muscular rheumatism* many believe that it is not merely of value as a symptomatic drug, but that it possesses some curative effect. As an antipyretic it is employed in the same class of cases as the aniline derivatives. It is also used in certain spasmodic disorders, especially *whooping-cough* and *epilepsy.* In the latter disease it usually fails when given alone, but appears to enhance the action of the bromides.

It is a valuable local remedy in the treatment of various inflammatory conditions of the mucous membranes, as *rhinitis* and *laryngitis,* both for its local anesthetic and vasoconstricting effects. For this purpose it is usually employed in strengths of from 5 to 15 per cent. It is occasionally used as a styptic in *nasal hemorrhage.*

Toxicology.—Antipyrine, like the other coal-tar derivatives, is prone to produce unpleasant and sometimes alarming symptoms, even after doses which would scarcely be regarded as excessive. The most common type of antipyrine poisoning is characterized by giddiness, tremor, free sweating with more or less collapse, a peculiar lividity with, in many cases, eruption of the skin most commonly morbilliform, but sometimes erythematous or urticarial. After very large doses there may be drowsiness deepening into coma with dilatation of the pupil and epileptiform convulsions. Various irregular symptoms have been noted, such as amaurosis, pseudo-membranous stomatitis, swelling of the lips and tongue, laryngeal interference with the respiration. In some cases fever with nervous unrest and epileptiform convulsions have been reported.

The treatment of antipyrine poisoning is purely symptomatic. Circulatory stimulants, as ammonia, strychnine and atropine, should be given and the bodily temperature maintained by the external application of heat.

Dose, from five to fifteen grains (0.3–1.0 Gm.)

ANTITOXINUM DIPHTHERICUM

DIPHTHERIA ANTITOXIN

ANTITOX. DIPH. [Serum Antidiphthericum Purificatum, U. S. P. IX, Concentrated Diphtheria Antitoxin, Refined Diphtheria Antitoxin, Antidiphtheric Globulins.]

"Diphtheria Antitoxin is an aqueous solution of certain antitoxic substances obtained from the blood serum or plasma of an animal of the genus *Equus,* which has been properly immunized against diphtheria toxin. After the serum or plasma from the immunized animal has been collected, the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water. Sodium chloride and a preservative are then added and the solution is filtered through a bacteria-excluding filter. It has a potency of not less than 350 antitoxin units per cc." *U. S.*

Serum Antidiphthericum, *P. G.;* Diphtherie-Heilserum, *G.;* Sérum antidiphtérique, *Fr.;* Siero antidifterico, *It.;* Suero antidifterico, *Sp.*

Formerly the U. S. Pharmacopœia recognized three forms of diphtheria antitoxin under the names respectively of *Serum Antidiphthericum, Serum Antidiphthericum Purificatum,* and *Serum Antidiphthericum Siccum.* At the tenth revision the first and last of these was dropped because of the rarity of their employment. The substance formerly official as purified antidiphtheric serum is now recognized under the name of diphtheria antitoxin. For the natural or unpurified serum of the former pharmacopœia there is no place in medicine today. For the dried serum, however, there is a limited field of usefulness which is based upon the fact that it does not deteriorate so rapidly as the liquid and is occasionally useful for transportation far from centers of manufacture.

The antitoxic property of the blood serum of animals immunized by the inoculation of bacterial toxins was discovered in 1890 by Behring and Kitasato (*D. M. W.,* 1890, Nos. 49, 50). The great practical therapeutic value of diphtheria antitoxin was demonstrated independently by Behring and by Roux and announced in papers read before the International Congress of Hygiene and Demography which met in Budapest in 1894.

Only the serum of the blood is used in medicine for prophylactic or curative purposes, although other body juices contain the active principle. The antitoxin has never been isolated in pure form. It is precipitated with the globulins and is believed to be allied to the enzymes. The antitoxin globulin retains its properties more persistently than the allied globulins with which it is associated. That is, it is more resistant to deleterious influences, more stable and more soluble than the other globulins found in blood serum. As we lack definite knowledge of the true chemical nature of the active principle contained in antitoxic serums, the antitoxin is variously spoken of as *antikörper* (G.) or *antibodies,* free receptors (Ehrlich), *cytases*

(Metchnikoff), etc. Of the several antitoxins known, diphtheria and tetanus antitoxins are the only ones recognized by the U. S. Pharmacopœia. These are the only ordinary diseases caused solely by a soluble toxin; in other words, in these two diseases, not the bacteria themselves, but the poison which they excrete, produce the severe symptoms and frequent fatalities. And these two toxins, in the animal body, each give rise to an antitoxin which may be therapeutically or prophylactically efficient. Each antitoxin is specific; that is, neutralizes the poison of the particular infection which was inoculated into a susceptible animal to produce it. While diphtheria antitoxin is used for other diseases, it is specific only in neutralizing the poisons produced by the diphtheria bacillus. Diphtheria antitoxin is sometimes normally present in small amounts in the blood serum of horses, man and other animals.

Preparation.—Diphtheria antitoxin is made by injecting the diphtheria poison (toxin) into horses. The horses are injected either subcutaneously or intravenously; usually the former method is preferred. Horses are selected because, on account of their size, a large amount of blood may readily be obtained, and because the serum of the horse is more easily borne by the human organism in large quantities than that of most other animals. Behring originally employed dogs and sheep with success; Aronson preferred the goat; Roux was the first to use the horse.

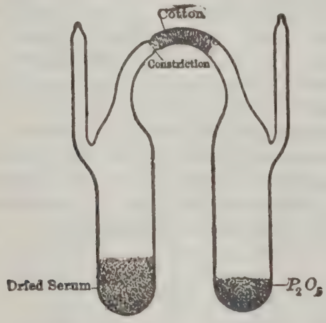
The antitoxin is produced by a vital reaction of the cells of the body caused by the stimulation of the toxin. Just which cells of the body take most active part in the production of the antitoxin is not exactly clear. Metchnikoff believed this power lies almost solely with the phagocytes, while Ehrlich believed that any of the body cells, but especially the connective tissue cells, play the most important rôle. The followers of Ehrlich and Metchnikoff have built up two divergent schools of thought to account for antitoxin immunity. It is interesting to note that both schools place the nutrition and metabolism of the cell at the ground work of antitoxin production.

The toxin is made by growing a virulent culture of the diphtheria bacillus in an alkaline nutrient bouillon at about 37° C. This culture, when five to seven days old, is filtered through unglazed porcelain or diatomaceous earth in order to remove the bacterial cells. The clear filtrate, containing the soluble poisons elaborated by the growth and multiplication of the bacilli, is the *diphtheria toxin.* The horse is inoculated with increasing amounts of the toxin. At first very small amounts are used, but even these usually cause a local and constitutional reaction, swelling and edema at the site of inoculation, fever, and derangement of appetite. These symptoms pass away in a few days, when a larger quantity of toxin is then inoculated, and this process is continued until within a few months the horse is able to withstand the subcutaneous inoculation of as much as a liter of a strong toxin with perhaps less local and general disturbance than is caused by the first treatment with a very small fraction of this amount.

As the doses of toxin given to the horse increase, the amount of antitoxin in the blood gradually increases until, after three to six months of treatment, the horse's blood usually contains from 300 to 800 units of antitoxin to the milliliter. The production of stronger antitoxic serums depends upon the horse and not upon the treatment. Some horses react actively and produce very high potency serums for long times; others cannot be induced to give a serum containing more than 150 to 200 units per milliliter. After a variable period (from several months to years) the horse loses the power of reaction, so that despite active treatment the immunizing power of the blood serum steadily diminishes. The horse is bled from the external jugular vein by means of a trocar and cannula. The blood is drawn into long sterile cylindrical tubes or other vessels containing sodium citrate or calcium oxalate solution and allowed to sediment. In about 24 hours the clear supernatant plasma is siphoned off and a preservative is added. The plasma so obtained from a number of horses is mixed and the antitoxic bearing globulins are separated by precipitation with ammonium sulphate, followed by dialysis to remove the sulphate. The remaining globulins bearing the antitoxin have sodium chloride and a preservative added and the solution is then passed through a sterile filter stone. The antitoxin is then tested for potency, for freedom from toxins and for sterility. After these tests are completed it is ready to be filled into the final container.

Preservatives.—The antitoxin in the blood serum neutralizes the toxin when the two are brought into contact, but the antitoxic serum does not prevent the growth of the bacteria themselves. Diphtheria bacilli grow and multiply well in diphtheria antitoxic serum. In other words, diphtheria antitoxin is a good culture medium for bacteria of all kinds. The greatest care must therefore be taken to prevent contamination. The serum may be kept sterile indefinitely only by means of the most exacting bacteriological precautions. It is sometimes marketed without the addition of an antiseptic substance, but this practice has been largely discontinued for the following reasons: (1) The technic required to prevent slight accidental contamination during the process of preparation and bottling is arduous; (2) there is danger of the introduction of serious contamination by unskilled persons who use the serum; (3) the addition of a small amount of certain preservatives is harmless. The serums made by the American manufacturers generally contain cresol (0.4 per cent.), phenol (0.5 per cent.), or chloroform (to saturation).

The preparation and preservation of the standard antitoxin is encompassed by many technical difficulties. A high-grade serum is selected. This is given a preliminary test to determine its potency. The serum is now reduced to dryness by evaporation *in vacuo*. Special apparatus is used to accomplish this evaporation quickly and at the same time to prevent contamination. The dried antitoxic serum must be kept guarded under special conditions to prevent deterioration. The oxygen of the air must be excluded in order to retard the process of oxidation, which rapidly alters the antibodies, especially under the influence of light; the standard antitoxin is, therefore, always kept under a vacuum and in absolute darkness in the Hygienic Laboratory of the U. S. Public Health Service. The serum must be perfectly dry; it is therefore kept under the influence of phosphoric anhydride, P_2O_5. Further, it is kept in a specially built ice-box maintained at the constant temperature of 5° C. by means of circulating brine. The dried serum is preserved in a small glass apparatus consisting of two parts connected by means of a glass tube, as shown in the accompanying illustration. The dried serum is placed in one portion of the apparatus and phosphoric anhydride, which is a very powerful dehydrating substance, in the other. The air is exhausted as much as possible by means of a high vacuum and the apparatus hermetically sealed. Several hundred such tubes are prepared, each one containing a weighed quantity of the powdered serum. From this arrangement, it will be seen that the antitoxin is kept dry, free from contact with the oxygen of the air, guarded against the action of light, and preserved at a constant low temperature. Once every two or three months, or whenever it is desired to prepare the standard solution, one of these bulbs is broken and 1 gramme of the dried serum carefully weighed and dissolved in a solution made by mixing physiological saline solution (0.85 per cent.) one part, and pure glycerin two parts.



U-shaped tubes used for preserving the standard serum. Half size.

Testing the Standard Antitoxin.—This glycerinated solution of blood serum is now accurately compared with previous standard solutions in terms of the immunity unit. This comparison is made by means of the test (L +) dose of toxin. The L + dose of a toxin is that quantity which when mixed with one immunity unit of serum is just able to kill a 250-gramme guinea pig on the fourth day (about 96 hours). In the commercial testing of antitoxin in order to have a coefficient of safety it is better to require the pig to live.

Testing the Toxin.—The toxin is a complex substance composed, according to Ehrlich, of several poisons, *e.g., toxin, toxoid, toxone* and *epitoxonoid*. The diphtheria toxin is first investigated biologically by adding varying quantities of the poison to the immunity unit and inoculating the mixtures into a series of guinea pigs. In this way, it is very evident, as Ehrlich has shown, that two limits, boundaries or zones are always shown, which are of the greatest importance in determining the nature and composition of the poison. Each of these limits is designated by the letter L, from *limes*, a boundary or zone. These limits are known respectively as L_0 (O = nil) and L + (+ = death).

By L_0 is meant that quantity of poison which just neutralizes or saturates one immunity unit as shown at the necropsy done forty-eight hours after the subcutaneous injection of the mixture into the guinea pig. The reaction at the site of inoculation at this examination must be hardly noticeable. Theoretically the L dose of toxin must unite with and neutralize just 200 "combining units" of antitoxin. A "combining unit" of antitoxin is in theory one two-hundredth of an immunity unit, and is supposed to contain enough antitoxin to just neutralize one fatal guinea pig dose of a pure toxin which is all poison without the comparatively inert (but antitoxin-neutralizing) toxoids and toxones. The L_0 dose, therefore, contains just 200 minimal lethal doses of a theoretically pure poison.

By L + is meant the smallest quantity of toxin of which when mixed with one immunity unit of antitoxin there is left unneutralized a quantity to kill the animal on the fourth day. As defined by Ehrlich the L + dose is that quantity of poison which, despite the antibodies contained in one immunity unit of serum, contains a sufficient excess of poison to cause the death of the guinea pig within the course of four days.

In studying the constitution of the diphtheria poison it is also necessary to determine its absolute toxicity with the greatest possible precision. The absolute toxicity of the diphtheria poison is expressed as the minimal lethal dose (MLD), sometimes spoken of as the minimal fatal dose (MFD); and occasionally simply as the lethal dose. The minimal lethal dose may be readily defined as the smallest quantiy of toxin which will surely kill every guinea pig weighing 250 grammes in the course of four days, or at the latest, five days. As Ehrlich has pointed out, such a quantity may kill some of the animals sooner, that is, within thirty-six to forty-eight hours. A quantity of diphtheria poison that will kill every guinea pig, without exception, acutely within thirty-six to forty-eight hours contains more than the minimal lethal dose. The L + dose is a much more definite and constant measure than the MLD. It does not show the irregularities or present the difficulties met with in determining the absolute toxicity of the poison. On account of the importance of the L + and the L_0 doses the following simplified tables taken from actual experiments are given to show just how the two are made:

Test to determine the L + dose of a toxin.

	Result.
1 immunity unit + 0.19 cc. toxin	Invariably causes late paralysis, never acute death.
1 immunity unit + 0.20 cc. toxin	Sometimes causes late paralysis and sometimes acute death.
1 immunity unit + 0.21 cc. toxin	Always causes acute death about the fourth day.
I immunity unit + 0.22 cc. toxin	Always causes acute death, usually on the second or third day.

The L + dose of this toxin is, therefore, just 0.21 cc.

Tests to determine the L_0 dose of a toxin.

	Result at autopsy 48 hours after inoculation.
1 immunity unit + 0.14 cc. toxin	No visible reaction.
1 immunity unit + 0.15 cc. toxin	No visible reaction.
1 immunity unit + 0.16 cc. toxin	Slightest possible congestion about carbon particles or no reaction.
1 immunity unit + 0.17 cc. toxin	Apparent reaction at site of inoculation.
1 immunity unit + 0.18 cc. toxin	Injection and edema at site.
1 immunity unit + 0.19 cc. toxin	Injection and edema at site.

The L_0 dose of this toxin, therefore, is 0.16 cc.

Description and Physical Properties.—"A transparent or slightly opalescent liquid, with sometimes a slight granular deposit, of a faint brownish, yellowish or greenish color, nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. Diphtheria Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or 0.4 per cent. of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

"Diptheria Antitoxin must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The requirements for labeling are that the outside label must bear the name *Diphtheria Antitoxin* and the minimum number of units in the package, the lot number of the antitoxin, the name, address and license number of the manufacturer, and a statement of the date beyond which the minimum potency may not be maintained. This date is one year from date of issue from the manufacturing establishment if an excess of 20 per cent. over the minimum potency has been placed in the container, two years for a 30 per cent. excess, three years for a 40 per cent. excess, or four years for a 50 per cent. excess.

"The strength shall be expressed in units of antitoxic power, and the unit shall be that of the standard Diphtheria Antitoxin distributed by the Hygienic Laboratory of the United States Public Health Service. Diphtheria Antitoxin must be dispensed in the unopened glass containers in which it was placed by the manufacturing establishment, and it should be *preserved* at a temperature between 4.5° and 20° C., preferably at the lower limit." *U. S.*

Legal Requirements.—All diphtheria antitoxin and other biologic products sold in interstate commerce in this country must comply with the regulations made in accordance with the Law approved July 1, 1902, entitled "An Act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." It is illegal to sell, barter, or exchange diphtheria antitoxin made in one State or Territory or the District of Columbia in another State or Territory or the District of Columbia unless the following salient points of the law have been complied with: 1. The product must be plainly marked with the proper name of the article contained therein: 2. The label on the package must plainly state the name and address of the manufacturer. 3. The package must be plainly labelled with the license number issued by the Secretary of the Treasury. 4. The date beyond which the contents cannot be expected, beyond reasonable doubt, to yield specific results, must be given on the label or package. The execution of the law rests with the Surgeon-General of the U. S. Public Health Service. Annual inspections of all licensed manufacturers are made by officers of the above named service. From time to time products of each licensed manufacturer are bought on the open market and examined in the hygienic Laboratory of the Public Health Service at Washington for purity and potency.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE for the immunization of susceptible persons against diphtheria. Because of the shortness of the duration of passive immunity, within recent years there has been introduced a method of producing active immunity by the injection of a mixture of the diphtheria toxin and antitoxin.

The protection against diphtheria afforded by injections of diphtheria antitoxin alone is passive and continues not more than three or four weeks. Active immunity such as that capable of being produced through the use of diphtheria toxin, on the contrary, usually lasts three years or longer.

Following the experimental work of Behring, Park and his associates succeeded in developing a modification by combining in a single product, diphtheria toxin and diphtheria antitoxin, to which they gave the name *Diphtheria T. A. Mixture.* The antitoxin is added to the diphtheria toxin solely for the purpose of robbing it of its irritant action on the tissues at the point of injection and thus allowing a large dose of the modified toxin to be injected.

Park and his assistants have employed active immunization with toxin-antitoxin mixture in a large number of susceptibles, including 1000 infants under one week old, without the subsequent occurrence of a single case of diphtheria. Park summarizes his observations as to the value of active immunization as follows:

"The procedure is absolutely harmless. No reaction develops in infants, while in older children and adults a moderate swelling of the arm may appear and last for from one to three days.

"One injection gives immunity to 80 per cent. of those previously susceptible, two injections give immunity to 90 per cent., and three injections to 97 per cent.

"The immunity conferred lasts for three years, and probably much longer.

"No diphtheria has occurred in those so far immunized."

The Toxin-Antitoxin Mixture originally used by Park and colleagues was made so that each cubic centimeter contained 3 L + doses of toxin properly neutralized by antitoxin. This preparation, while efficient, sometimes produced marked protein reactions in older children and adults. More recent work has shown that a formula containing 0.1 L + dose of toxin per cubic centimeter has the same immunizing effect as the old formula preparation with the objectionable features of the older preparation removed.

Preparation.—Diphtheria toxin-antitoxin is prepared by combining the required amount of an aged, accurately standardized diphtheria toxin and diphtheria antitoxin (for method of preparation of both, see under diphtheria antitoxin). The mixture is made in such proportions that it contains one-tenth of an L + dose of toxin and sufficient amount of antitoxin to have enough unneutralized toxin that one cc. will not cause the death of a 250-gramme guinea pig, but 5-cc. doses will cause acute death of most of the animals injected. The mixture must conform to all of the requirements of the Treasury Department for biologic products sold in interstate commerce.

Dose, 1 cc. injected subcutaneously for three doses given at intervals of 7 days.

DIPHTHERIA TOXIN FOR THE SCHICK TEST.—What is known as the *Schick Test* for the determination of immunity to diphtheria is widely employed for that purpose, especially in children of school age. The test consists in the intracutaneous injection of one-fiftieth the minimal lethal dose of diphtheria toxin for guinea pigs. If the individual injected is immune to the disease no reaction will occur, but if susceptible, a local reaction will develop on 24 to 48 hours. The test is of particular value in institutions, in localized outbreaks of diphtheria and for the detection of susceptibles with a view to their later immunization with toxin-antitoxin mixture. The test material consists of accurately standardized diphtheria toxin with sterile normal salt solution as a diluent. The formula generally used is one in which one-fiftieth of a minimal lethal dose of toxin for a guinea pig is contained in 0.2 cc. of the final dilution. The diluted toxin quickly loses in potency and must always be freshly prepared. The injection must be made intracutaneously—that is into, not beneath, the skin, and preferably on the flexor surface of the forearm. In Schick Tests of children over six years of age, it is advisable to make a control test by the injection of a similar amount of the same dilution which has been heated to 75° C. for 10 minutes The control test enables the observer to eliminate reactions due to the protein in the toxin and blood of the person tested.

The percentage of positive reactions varies greatly at different ages, the highest percentage of positive reactions occurring in children between six months and four years of age.

Uses.—Diphtheria antitoxin is a true specific for diphtheria if it is given in sufficient quantity and sufficiently early in the disease. The very unfavorable results obtained in England in 1895 in the treatment of *diphtheria* with serum were due, according to the report of the Lancet Commission (*L. L.,* July 19, 1896), in a great majority of cases, to the uses of serum too weak to produce therapeutic results. Experimental researches, for example, the very careful work of Madsen in Copenhagen in 1896, showed that for therapeutic purposes weak serum is of very little value. Equally disappointing results will be obtained if the antitoxin is administered after the toxine has damaged the cells. The early use of the remedy is of the greatest importance. No time should be lost, not even delay in waiting for bacteriological confirmation. As soon as diphtheria is suspected, 10,000 units of antitoxin should at once be injected into the subcutaneous or intramuscular tissue.

The following figures, from the Philadelphia Hospital for Contagious Diseases, show even more convincingly the great value of the early administration of antitoxin as well as general average reduction of mortality by antitoxin.

Mortality of Diphtheria According to Day on which Antitoxin was first injected in 8591 consecutive cases.

Day of illness	Number of patients	Deaths	Per cent. mortality
First	329	5	1.52
Second	2269	77	3.39
Third	2407	165	6.85
Fourth	1612	176	10.91
Fifth	911	136	14.92
Sixth	416	54	12.98
Seventh	320	53	16.56
Unknown	327	50	15.29
Totals	8591	716	8.33

In Boston, a city which has suffered severely from diphtheria and where the antitoxin treatment has been particularly thorough, the reduction in the death rate has been striking. In the Boston City Hospital the death rate between 1888 and 1894 was only once below 40 per cent.; since 1895, when antitoxin was introduced, it has not once reached 15 per cent. (J. H. McCallum). Numerous statistics from all parts of the world upon the effect of the antitoxin treatment of diphtheria are practically unanimous in showing the good results of this remedy. The great value of diphtheria antitoxin is perhaps most strikingly seen in the laryngeal cases (*"membranous croup"*).

The standard curative dose is 10,000 units administered at once, though mild cases require less and severe ones more—particularly if not seen at the early stage The entire amount needed should be given at one dose, intravenously if the case is urgent. A vein at the bend of the elbow may be punctured with the injection needle under aseptic precautions, and the antitoxin slowly introduced. Fortunately the serum is usually harmless even when injected in large quantities. The remedy should always be given by the hypodermic, intramuscular, or intravenous method. Strict asepsis must be observed. The liquid may be injected under the skin of any part of the body where the subcutaneous tissue is loose. The back, near the angle of the scapula, is a favorite site for inoculation; sometimes the flank or abdominal walls are chosen. The intramuscular route is more rapid and hence more effective than the subcutaneous; the heavy musculature of the buttocks is usually chosen for this method. If improvement is not manifest after a few hours more antitoxin should be given, though this implies that the first dose was too small. It is the early administration rather than the large quantity which is most efficient. The exhibition of the remedy by the mouth or per rectum is practically valueless.

Diphtheria antitoxin is just as valuable for prophylaxis as for curative purposes. The passive immunity produced by the inoculation of the antitoxic serum does not last very long. The transitory nature of the immunity afforded by prophylactic injections is probably dependent upon the fact that the antitoxin-bearing horse serum, being a foreign protein, is broken down in the human body and excreted by the kidneys. The usual prophylactic dose is 1000 units. If the exposure to the infection continues, the dose should be repeated in two weeks, or, preferably, use the toxin-antitoxin mixture described above. The antitoxin in the blood neutralizes the toxin elaborated by the bacilli growing on the mucous membrane of the throat, but has no deleterious effect upon the bacteria themselves. The microorganisms in this situation may continue to grow and remain virulent for months. This is the explanation of occasional failures of the antitoxin to prevent a subsequent attack of the disease.

Although the injection of the serum is usually harmless, there are certain individuals who are abnormally sensitive to horse serum in which the injection may cause unpleasant reactions or even, in rare instances, death. Two types of reactions of this kind have been reported, one characterized by urticaria and sometimes pains in the joints, which usually passes away in a few days without further ill-consequences. In the other type there occurs asthmatic paroxysms of greater or lesser severity which, in some instances, has lead to complete obstruction of respiration and consequent death. In patients who are subject to asthma, especially of the so-called "horse asthma," the treatment is fraught with considerable danger. MacKenzie (*J. A. M. A.*, 1921, lxxvi, p. 1563) recommends in all cases of doubt the intracutaneous injection of 0.002 cc. (${}^1/_3$ minim) of horse serum. In sensitive individuals there occurs within a half hour a reaction shown by the appearance of a wheal surrounded by a zone of erythema. The method of desensitizing such individuals suggested by Besredka, which is often although not universally successful, consists in the intravenous injection at intervals of from five to ten minutes of increasing doses of the serum beginning with very little quantities. These unpleasant reactions are much less frequent since the use of the purified antitoxin; they are also less likely to occur when the antitoxin is given subcutaneously than when administered intravenously. Leyton (*L. L.*, June 10, 1916) recommends scopolamine, especially if combined with morphine to prevent the anaphylactic reactions. In any case, however, the danger from diphtheria is greater than the danger from serum reaction (anaphylaxis), and the antitoxin should not be withheld.

Diphtheric antitoxin gradually loses its strength, especially when kept under unfavorable conditions of light, temperature, etc. The loss in one year is usually from 10 to 30 per cent.; however, a serum will retain considerable antitoxic potency after years. Except for its diminished potency an old serum is quite as good as one freshly prepared; so that in an emergency or in order to save time an old serum may be administered, provided it remains uncontaminated.

Dose, prophylactic, 1000 units; curative, 10,000 units or more.

ANTITOXINUM TETANICUM. U. S.

TETANUS ANTITOXIN

ANTITOX. TET. [Serum Antitetanicum Purificatum, U. S. P. IX, Concentrated Tetanus Antitoxin, Refined Tetanus Antitoxin, Antitetanic Globulins.]

"Tetanus Antitoxin is an aqueous solution of certain antitoxic substances obtained from the blood serum or plasma of an animal of the genus *Equus,* which has been properly immunized against tetanus toxin. After the serum or plasma from the immunized animal has been collected, the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water. Sodium chloride and a preservative are then added and the solution is filtered through a bacteria-excluding filter. It has a potency of not less than 300 units per cc." *U S.*

Tetanus-Heilserum, *G.;* Serum Antitetanique *Fr.;* Siero Antitetanico, *It.;* Suero Antitetanico, *Sp.*

This antitoxin takes the place of the formerly official *Serum Antitetanicum Purificatum.*

The discovery of tetanus and diphtheria antitoxins was simultaneous, Behring, who worked principally on diphtheria, and Kitasato who worked on tetanus publishing their results together (*D. M. W.,* 1890, Nos. 49, 50) from the Hygienic Institute in Berlin under Robert Koch. In general the method of preparation is the same as that described under *Serum Antidiphthericum.* The purified and dried tetanus toxin is the most powerful poison known, the fatal dose for mice being as low as 0.000,000,05 gramme. There are at least two toxins produced by the tetanus bacillus—*tetano-spasmin,* which causes the muscular contractions typical of the disease, and *tetano-lysin,* which destroys the red corpuscles of the blood. The former is by far the more important, giving the symptoms of rigidity (*e.g.,* lockjaw), and tonic convulsions by which the disease is recognized in man and animals, and causing the high mortality. This poison is absorbed by the end-plates of the nerves in muscle, and travels up these motor nerves to the ganglion cells of the central nervous system. It is the passage along the nerves which occupies the greater part of the time of the incubation period.

Preparation.—The chief difference in method of preparation from that used in the case of diphtheria antitoxin lies in the fact that the tetanus bacillus belongs to the group of bacteria known as obligatory anaerobes, that is, those which thrive only in the absence of oxygen—and in the further fact that the poison formed by the tetanus bacillus is very unstable and rapidly loses in strength under ordinary conditions. The former difficulty is overcome by growing in deep vessels containing specially prepared broth which has been freshly heated to drive off the oxygen; and the latter by using the toxin soon after preparation or by storing it under special conditions.

Description and Physical Properties.—"A transparent or slightly opalescent liquid, with sometimes a slight granular deposit, of a faint brownish, yellowish or greenish color, nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. Tetanus Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or 0.4 per cent. of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

"Tetanus Antitoxin must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The requirements for labeling are that the outside label must bear the name *Tetanus Antitoxin* and the minimum number of units in the package, the lot number of the antitoxin, the name, address and license number of the manufacturer, and a statement of the date beyond which the minimum potency may not be maintained. This date is one year from date of issue from the manufacturing establishment if an excess of 20 per cent. over the minimum potency has been placed in the container, two years for a 30 per cent. excess, three years for a 40 per cent. excess, or four years for a 50 per cent. excess.

"The strength shall be expressed in units of antitoxic power, and the unit shall be that of the standard Tetanus Antitoxin distributed by the Hygienic Laboratory of the United States Public Health Service. Tetanus Antitoxin must be dispensed in the unopened glass containers in which it was placed by the manufacturing establishment, and it should be *preserved* at a temperature between 4.5° and 20° C., preferably at the lower limit." *U. S.*

The standard for tetanus antitoxin is the result of research done in the hygienic laboratory in conection with the governmental control of biologic products. (The Standardization of Tetanus Antitoxin, by M. J. Rosenau and John F. Anderson, *Hyg. Lab. Bull.,* No. 43, U. S. P. H. S., March, 1908.) This method of standardization is distinct from any previously in use, but, since its adoption in this country, has come to be used to a large extent outside the United States as well. As with diphtheria antitoxin, the ultimate standard unit is a definite amount of dried serum kept under special condition at Washington. The technic of the preparation, storage, weighing, and solution of this antitoxin is the same as in the case of the diphtheria standard. The medium of measurement, however, is a standardized toxin which is likewise dried and preserved in vacuum tubes in the absence of moisture, and sent out to the establishments in various parts of the world manufacturing tetanus antitoxin. On account of the hygroscopic quality of this dried poison and its extreme instability in the presence of moisture, it is necessary that the tubes be kept after opening in a vacuum desiccating chamber at a low temperature and protected from light. For each use the powder must be weighed quickly on delicate balances and computation made for gain in weight due to absorption of moisture. Any deterioration in the toxin may be detected by testing with the standard antitoxin or by ascertaining the minimal lethal dose (MLD), which is stated for each tube of toxin when sent out.

The animal used for testing tetanus antitoxin by the American standard is the guinea pig. The standard weight is 350 grammes, and the test dose of the toxin when mixed with one-tenth unit of antitoxin, should kill the guinea pig in about ninety-six hours.

Tetanus antitoxin, as well as all similar products, is tested for sterility by planting in suitable culture media and incubating for a number of days, and for presence of toxin, excess of preservative, or other deleterious content, by animal inoculation.

For other legal requirements, see *Serum Antidiphthericum,* U. S.

Uses.—Tetanus antitoxin has achieved its great success as a preventive rather than as a curative measure. Though in times of peace *tetanus* is not a common disease, the tetanus bacillus is ubiquitous and in its spore form, very long lived; its relative infrequence as a cause of sickness and death is due to the excellence of the bodily defenses against it. As explained above, the tetanus bacillus requires an absence of oxygen to thrive; this is not obtained unless the organism is introduced deep below the surface of the skin or under a tight covering, is accompanied by other organisms which absorb the oxygen, or has necrotic tissue as a nutrient. Even if so introduced, the natural antagonism of the body fluids or the wandering cells of the blood may render the invasion harmless. There is abundant evidence, however, that when the above conditions are favorable to its development, the tetanus bacillus produces a high mortality among wounded, and that this mortality is due to the toxin alone. Aside from the occasional tetanus infection when an ordinary wound is contaminated with dirt, and the cases of *tetanus neonatorum* now fortunately obsolete with the advent of asepsis in labor and in treatment of the umbilical cord, there are three large causes of tetanus: Fourth of July wounds—the laceration from explosion at short range driving contaminated material deep into the tissues; operation and wounds of horses—since horse manure is one of the most prolific sources of the tetanus bacillus; the wounds of warfare, particularly on cultivated terrain. In each of these three classes we have evidence of the value of tetanus antitoxin as a preservative.

In St. Louis, where tetanus had been common following Independence Day, the institution of serum treatment in 1904 was followed by entire absence of tetanus among those so treated. For the whole United States, where the growing use of tetanus antitoxin has been parallelled with decreasingly violent celebrations, the reduction in fatality is striking, the deaths from tetanus having fallen from 406 in 1903 to 1 in 1915, while the ratio of deaths from tetanus to total deaths from fireworks has fallen from 1 in 1.15 (406 out of 466) to 1 in 30, thus indicating that the tetanus prophylaxis has outstripped the general measures of safety.

The veterinary use of tetanus antitoxin in this country has repeatedly eliminated the disease among horses where it had previously been endemic. In France tetanus following operations on horses had been extremely common until the use of antitoxin was instituted, when the tetanus ceased except in the practice of those veterinarians who did not use the antitoxin.

All observers in the European war hospitals agree that when tetanus antitoxin was difficult to procure, in the early part of the war, the mortality from tetanus was high; but when properly standardized potent serum became available and was thoroughly administered, tetanus was rare. From official statistics of this military experience it seems clear that in all wounds, except the slight ones which heal quickly, the prophylactic injection of tetanus antitoxin should be repeated at weekly intervals until the wound is healed, and wounded soldiers should receive a prophylactic dose when operated upon, even though the original wound be closed.

The results with tetanus antitoxin as a curative agent in the presence of the developed disease have not been as satisfactory as is the case with diphtheria antitoxin in the treatment of diphtheria. Nevertheless, there seems to be a general agreement with American surgeons, as well as those abroad, that the mortality is reduced at least 20 per cent. as a result of the use of tetanus antitoxin. As is the case with diphtheria, the mortality is greater the longer the interval elapsing between the onset of symptoms and the time treatment is begun. It also appears that the previous administration of a prophylactic dose of antitoxin has some influence on the outcome of the disease which may later develop. According to some of the British Army reports in the recent war, the mortality was about 35 per cent. among those who developed the disease after the prophylactic injection of antitoxin, and 71 per cent. among those who had not a prophylactic treatment. Intensive treatment, however, particularly intraspinal injection, apparently gives a lower death rate than is usual with tetanus treated without antitoxin. The technic for intraspinal medication is described under *antimeningococcus serum* in Part II.

For prophylaxis 1500 units should be injected subcutaneously in case of any wound contaminated with dirt, caused by an explosive, or accompanied by severe mutilation of tissue. This injection should be repeated at weekly intervals until the wound has healed. It is also important that all such wounds receive thorough surgical attention, with wide opening and cleansing, removal of tissue likely to necrose, and repeated antiseptic dressings. For treatment, about 5000 units should be given intraspinally as promptly as possible, and 10,000 units intravenously at the same time; unless the serum is of low viscosity, it may well be diluted with sterile salt solution for intraspinous injection. The intraspinal dose may be repeated daily and the larger dose repeated subcutaneously a few days later to keep the blood saturated with antitoxin. The powdered antitoxin is sometimes used as a dusting powder on wounds, but absorption in this method is uncertain; chief reliance in prophylaxis must be placed in subcutaneous injection.

Hypersusceptibility to horse serum should be guarded against in the use of tetanus antitoxin as in the case of diphtheria antitoxin. The deterioration of the two serums is also similar.

Dose, as a prophylactic, 1000 to 2000 units; as a curative, 10,000 to 20,000 units.

ANTITOXINUM TETANICUM CRUDUM. U. S.

CRUDE TETANUS ANTITOXIN Antitox. Tet. Crud.

[Serum Antitetanicum, U. S. P. IX. Crude Antitetanic Serum, Unconcentrated Tetanus Antitoxin, Unrefined Tetanus Antitoxin.]

Crude tetanus antitoxin is a fluid, having a potency of not less than 150 units per cc., separated from the coagulated blood of an animal of the genus *Equus,* which has been properly immunized against tetanus toxin.

Description and Physical Properties.—" A yellowish, or yellowish-brown, transparent, or slightly turbid liquid with sometimes a slight granular deposit, having the faint odor of horse serum or having an odor due to the presence of the antiseptic used as a preservative. Crude Tetanus Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent. of phenol or 0.4 per cent. of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

" Crude Tetanus Antitoxin must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The requirements for labeling are that the outside label must bear the name *Crude Tetanus Antitoxin* and the minimum number of units in the package, the lot number of the antitoxin, the name, address and license number of the manufacturer and a statement of the date beyond which the minimum potency may not be maintained. This date is one year from the date of issue from the manufacturing establishment if an excess of 20 per cent. over the minimum potency has been placed in the container, two years for a 30 per cent. excess, three years for a 40 per cent. excess, or four years for a 50 per cent. excess.

" The strength shall be expressed in units of antitoxic power, and the unit shall be that of the standard Tetanus Antitoxin distributed by the Hygienic Laboratory of the United States Public Health Service. Crude Tetanus Antitoxin must be dispensed in the unopened glass containers in which it was placed by the manufacturing establishment, and it should be *preserved* at a temperature between 4.5° and 20° C., preferably at the lower limit." *U. S.*

For preparation, preservatives, tests and uses, see *Antitoxinum Tetanicum.*

Dose, curative 10,000 units, protective 1500 units.

APII FRUCTUS. N. F.

CELERY FRUIT Apii. Fruct. [Celery Seed]

" Celery Fruit is the dried ripe fruit of *Apium graveolens* Linné (Fam. *Umbelliferæ*). Celery Fruit contains not more than 5 per cent. of unsound or foreign fruits or other foreign organic matter and yields not more than 3 per cent. of acid-insoluble ash." *N. F.*

Smallage; Marsh Parsley; Ache, Céleri, *Fr.;* Eppich, Cellerie, *G.;* Apio, *Sp.*

Description and Physical Properties.—" *Unground Celery Fruit.*—Mericarps united or separate, ovoid, slightly curved, 1 to 2 mm. long and about half as broad and half as thick; dark brown; inner surface flat; outer surface convex, smooth except for 5 very slender light-colored ribs, 2 of which are marginal. Odor characteristic, agreeable; taste aromatic, warm and somewhat pungent.

" *Structure.*—Mericarp nearly equilaterally pentagonal in transverse section; with 6 to 165 oil-tubes in the pericarp, the latter closely surrounding a somewhat pentagonal seed; epidermis of pericarp with tangentially elongated cells, the latter with a thick cuticle and occasionally developed into short, smooth papillæ; a fibro-vascular bundle in each of the ribs, composed of a few tracheæ and strongly lignified fibers; inner tissue of pericarp of tangentially elongated parenchyma with brownish walls; seed chiefly of endosperm parenchyma; seed-coat of several layers of yellowish more or less collapsed cells; endosperm of thick-walled polygonal cells containing fixed oil and aleurone grains, the latter each with a small rosette of calcium oxalate.

" *Powdered Celery Fruit.*—Brown and oily; fragments of the pericarp with yellowish oil-tubes, brown secretion cells and few epidermal papillæ; tracheæ and fibers; parenchyma cells of endosperm with aleurone grains, the latter usually containing rosettes of calcium oxalate, 0.002 to 0.008 mm. in diameter." *N. F.*

The celery plant is a hardy biennial native to Great Britain but cultivated in all parts of the temperate zone. In the wild state it has a rank disagreeable taste but by cultivation the leaves have lost their coarse taste and afford the familiar vegetable. The plant has a glabrous stem 1 to 3 feet high; the leaves are pinnate, the basal and lower being long-petioled and the upper short-stemmed. The small flowers are borne in umbels opposite the leaves.

Celery seed yields a volatile oil possessing the characteristic odor of the drug. This volatile oil consists chiefly of terpenes, but its odor appears to be due to two anhydrides: *sedanolid* $C_{12}H_{18}O_2$, the lactone of sedanolic acid, and *sedanonic anhydride* $C_{12}H_{18}O_3$.

Apium nodiflorum (L.) B. et H. (*Sium nodiflorum* L.) *Water parsnip.*—This is a perennial, umbelliferous, aquatic, European plant, growing also in the southern section of the United States. It is commonly considered poisonous; but the fresh juice has been used by Withering and others, in the *dose* of three to four ounces every morning, for scrofulous *lymphadenitis* and obstinate *skin diseases.*

Uses.—There is a popular superstition among the uneducated that celery seed has a sedative and tonic effect upon the central nervous system and it is sometimes added to mixtures intended for nerve tonics. There is, however, not the slightest reason to ascribe any therapeutic virtue to the drug.

Dose, from twenty to sixty grains (1.3–4 Gm.).

Off. Prep.—Fluidextractum Apii Fructus, *N. F.;* Elixir Guaranæ et Apii, *N. F.*

APOCYNUM. N. F.

APOCYNUM Apocyn. [Canadian Hemp]

"Apocynum consists of the dried rhizome and roots of *Apocynum cannabinum* Linné (Fam. *Apocynaceæ*). Apocynum contains not more than 5 per cent. of its stems or other foreign organic matter." *N. F.*

Canadian Hemp; Black Indian Hemp; Amy Root; Chanvre du Canada, *Fr.;* Canadische Hanfwurzel, *G.*

There are several indigenous species of this genus of very similar general aspect, the rhizome and roots of two of them being collected, viz.: *Apocynum cannabinum* L., and *A. androsæmifolium* L. Both plants abound in a milky juice, which is present in simple latex cells that occur in the cortex and pith of the stems and mesophyll of the leaves, and have a tough, fibrous bark, which, by maceration, affords a substitute for hemp; hence the common name. It was used by the Indians of California for making cordage and for weaving. Both species are indigenous to North America and widely distributed.

In *A. cannabinum* the stems and branches are upright or ascending, terminated by erect and close, many-flowered cymes, which are usually shorter than the nearly sessile leaves, and the corolla has nearly erect lobes, with the tube not longer than the lanceolate divisions of the calyx. In *A. androsæmifolium* or *dogbane* the branches are divergently forked, the leaves are slender petioled, the cymes loose and spreading, the open bell-shaped corolla with revolute lobes and a tube much longer than the ovate-pointed divisions of the calyx. *A. cannabinum,* of which there are several well recognized varieties, grows in gravelly or sandy soil mostly near streams, while *A. androsæmifolium* grows in dry thickets and open woods. According to E. A. Manheimer, the root of the latter is distinguished from *A. cannabinum* by the thick-walled stone cells, which are arranged in an interrupted circle near the middle of the bark. (*A. J. P.,* Nov., 1881. See also *A. J. P.,* 1888.) Holm has contributed an article on the structure of *A. cannabinum.* (*Merck's Rep.,* 1910, p. 277.)

Description and Physical Properties.—"*Unground Apocynum.*—Cylindrical, somewhat branched, of varying length, 3 to 10 mm. thick, externally reddish brown to grayish brown; longitudinally wrinkled, occasionally with transverse fissures having vertical sides extending through the bark; fracture short; internal bark light brown, 1.5 to 3 mm. thick; wood radiate and with large tracheæ; pith small, in rhizome pieces only. Almost inodorous; taste starchy, afterwards becoming bitter and somewhat acrid.

"*Structure.*—Numerous laticiferous vessels in the bark and pith; cortex chiefly parenchyma cells, the latter filled with starch grains; wood with medullary rays, 1 to 2 cells in width and separating numerous narrow wedges of tracheæ and wood fibers; pith of thin-walled parenchyma, absent in the root. Stem portion with thin fibrous bark, a light brown porous wood and a large pith.

"*Powdered Apocynum.*—Light brown; numerous starch grains 0.003 to 0.020 mm. in diameter, spherical, ellipsoidal, ovate, pyriform or irregular, sometimes altered, swollen and with a hyaline central cleft; numerous fragments of strongly lignified wood fibers, the latter associated with tracheæ having bordered pores or spiral thickenings; few fragments of cork cells with reddish brown walls; occasional fragments with laticiferous tissues; stone cells few or absent." *N. F.*

The fresh root, when wounded, emits a milky juice, which concretes into a substance resembling caoutchouc.

The nature of the active principle of apocynum is as yet somewhat uncertain. Finnemore, in 1908, obtained from the *A. cannabinum* a crystalline substance to which the name of *cynotoxin* was applied. The following year Moore (*J. Chem. Soc.,* 1909, xcv) separated from the *A. androsæmifolium* a glucoside having the formula $C_{14}H_{18}O_3$, to which he applied the name of *apocynamarin.* These two principles, which appear to be identical, possess the characteristic physiological effects of the crude drug.

Taub and Fickewirth (*A. G. P.*, cliii, p. 239) believe that neither of these principles is chemically pure and that the activity of the plant is due to an intensely bitter principle which is not of glucosidal nature and to which they apply the name of *cymarin.* According to Windaus and Hermauns (*Ap. Ztg.*, 1915, 337) anhydrous cymarin has the formula $C_{30}H_{44}O_9$. Puckner (*J. A. M. A.*, 1914, lxiii, 1393) says it is not a glucoside although sensitive to acids. Cymarin has been studied pharmacologically by Impens and found to exert the characteristic effects of the drug.

Von Oefele (*Journ. Pharm. Elsass-Lothr.*, 1891, 325) described *apocynteine,* an alkaloid obtained from *A. venetum;* it is said to be a cardiac sedative.

Uses.—Apocynum was first called to the attention of the medical profession by M. L. Knapp in 1826, although its virtues seem to have been known to the aborigines. Subsequent to this date a number of clinicians employed it in the treatment of various dropsies and presented evidence that it was related to the digitalis group in its therapeutic effects. H. C. Wood, Jr. (*J. A. M. A.*, Dec. 24, 1904) has shown that, like digitalis, apocynum in moderate dose causes a slowing of the pulse and increase in the amplitude of the cardiac contractions and in toxic dose it causes marked increase in the systolic tone of the heart with great irregularity of its beat. In his experiments on the intact animal Wood found that the blood pressure was usually lowered because of the marked effect on cardiac inhibition, but that when the pneumogastric nerves had previously been divided there was a notable increase in the blood pressure, which he attributed chiefly to stimulation of the heart. Dale and Laidlaw (*Proc. Roy. Soc. of Med.*, Dec., 1909) have shown, however, that apocynum has a very marked stimulant action upon the vasomotor system. It appears to be more irritant to mucous membranes than either digitalis or strophanthus, and therefore is prone to cause nausea and catharsis. Perhaps this local stimulant effect is also the explanation of its very powerful diuretic action, although Dale and Laidlaw believe that the effect upon the kidneys is due chiefly to a relative dilatation of the renal arteries.

Although there is scarcely room for doubt that apocynum may be used as a substitute for digitalis in the treatment of chronic heart disease the careful studies of Marvin and White (*J. A. M. A.*, 1921, lxxvii, p. 1865) on patients suffering with auricular fibrillation show that it is ordinarily inferior in its action to digitalis. These authors found that doses large enough to control the cardiac irregularity produced almost uniformly nausea and vomiting and in several cases in which digitalis was afterwards used successfully, they were unable to obtain distinct benefit from apocynum. The older writers believe that it has a stronger effect upon the kidney and is especially of service in the treatment of *dropsies* both of those due to failure of the heart and the *ascites of hepatic cirrhosis.*

Cymarin has been used clinically by Bounsmann (*Med. Klin.*, 1921, xvii, 1522) and others as a cardiac stimulant and tonic in daily doses of one one-hundred-and-twentieth to one-sixtieth of a grain (0.5–1.0 milligramme) hypodermically.

Its irritant action upon the intestinal tract and irregularity of absorption militate strongly against its clinical usefulness; many patients are quite unable to take the drug because of the occurrence of emesis or purgation.

Dose, five to fifteen grains (0.32–1.0 Gm.).

Off. Prep.—Fluidextractum Apocyni, *N. F.*

"CAUTION.—It has been stated that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid possible toxic or cumulative action of the drug the physician should determine in each case the tolerance of the patient and regulate the dosage accordingly." *N. F.*

APOMORPHINÆ HYDROCHLORIDUM.
U. S., Br.

APOMORPHINE HYDROCHLORIDE

Apomorph. Hydrochl.

"The hydrochloride [$C_{17}H_{17}O_2NHCl.\frac{1}{2}H_2O$] of an alkaloid prepared from morphine by the abstraction of one molecule of water. *Caution.—Apomorphine Hydrochloride must be rejected if it at once imparts an emerald-green color to 100 parts of distilled water when shaken with it in a test tube.*" *U. S.* "Apomorphine Hydrochloride, $(C_{17}H_{17}NO_2,HCl)_2,H_2O$, is the hydrochloride of an alkaloid which may be obtained from morphine by the abstraction of the elements of a molecule of water." *Br.*

Hydrochlorate of Apomorphine; Chlorhydrate d'Apomorphine, *Fr. Cod.;* Apomorphinum Hydrochloricum, *P. G.;* Apomorphinhydrochlorid, *G.;* Cloridrato di apomorfina, *It.;* Cloruro de apomorfina, *Sp.*

Apomorphine was discovered by Matthiessen and C. A. Wright. It is prepared by heating morphine in a closed tube with a great excess of hydrochloric acid for two or three hours to the temperature of 140° to 150° C. The contents of the tube are then dissolved in water, an excess of sodium bicarbonate added, and the precipitate exhausted with ether or chloroform. On the addition to the solution of a very small quantity of hydrochloric acid, crystals of apomorphine hydrochloride form. The process is one of dehydration; the morphine parting with one molecule of water, the formula of apomorphine being $C_{17}H_{17}O_2N$. Apomorphine may also be made by the action of hydrochloric acid upon codeine, and it is affirmed that the best method in practice is that of E. Mayer, in which morphine is treated with a solution of zinc chloride, at 120° C. (*B. Chem. G.*, 1871, iv, 121.) Codeine, $C_{18}H_{21}O_3N$, when treated with hydrochloric acid, yields first $C_{18}H_{20}ClNO_2$, and then splits off methyl chloride, CH_3Cl, and leaves apomorphine, $C_{17}H_{17}O_2N$. Pschorr (*B. Chem. G.*, 1902, 4377) believes that apomorphine is a derivative of phenanthrenequinoline.

Description and Physical Properties.—"Minute, white or grayish-white glistening crystals, acquiring a greenish tint upon exposure to light and air. It is odorless. One Gm. of Apomorphine Hydrochloride is soluble in 50 cc. of water and in 50 cc. of alcohol, at 25° C. One Gm. is soluble in 17 cc. of water at 80° C. and is very slightly soluble in chloroform and in ether.

"The addition of a solution of sodium bicarbonate to an aqueous solution of the salt (1 in 100) produces a white, or pale greenish-white precipitate, which rapidly becomes green on exposure to air and when dissolved in ether, produces a violet color; in chloroform, a violet-blue color. Apomorphine Hydrochloride dissolves in nitric acid, producing a dark purple solution. Silver nitrate T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in nitric acid. This precipitate soon turns black by reduction to metallic silver, and is instantly reduced by the addition of ammonia water.

"A saturated aqueous solution of Apomorphine Hydrochloride is neutral to litmus paper. The ash from 0.2 Gm. is negligible. Shake 0.1 Gm. of the salt with 5 cc. of ether: the latter acquires not more than a pale reddish color (*decomposition products*).

"Preserve in small, dark amber-colored, well-stoppered vials, which have been previously rinsed with diluted hydrochloric acid and dried." *U. S.*

"Small grayish-white, shining, acicular crystals, turning green on exposure to air and light. Soluble in 60 parts of *water* and in 50 parts of *alcohol* (90 per cent.). The solutions decompose on boiling or keeping, with production of a green color; but remain unchanged for a considerable time if acidified with a trace of *hydrochloric acid.* Yields the *reactions* characteristic of chlorides. Gives a deep red color with dilute *T. Sol. of ferric chloride.* The addition of an aqueous solution of *sodium bicarbonate* to an aqueous solution (1 in 100) of Apomorphine Hydrochloride produces a white precipitate rapidly changing to green; this precipitate forms a purple solution with *ether,* a bluish solution with *chloroform,* and a green solution with *alcohol* (90 per cent.)." *Br.*

The alkaloid is colored dark red by nitric acid and rose red by ferric chloride, changing to violet, and finally black, on exposure. The aqueous and alcoholic solutions are at first colorless, if heated becoming pinkish, but change rapidly to greenish, finally becoming deep emerald green in color. This change in color has been attributed to oxidation, and it has been noticed that the solution on standing loses its power; for this reason it is best not to keep the solution, but to make it as wanted. C. Bernbeck affirms that the change in the solution to a green color may be prevented by the addition of a small quantity of hydrochloric acid, the decomposition being due to ammonia. (*Ph. Ztg.*, 1885.)

According to Max Quehl and H. Koehler, apomorphine is precipitated from its solutions, greenish by tannic acid, lemon yellow by picric acid, bluish-white—turning to sap-green—by copper sulphate on boiling, purplish by gold chloride, white—turning to blackish-violet—by potassium ferricyanide on boiling, blood-red by iodine in solution of potassium iodide, the precipitate disappearing on boiling, white and curdy by potassium sulphocyanate. (*A. J. P.*, 1873, p. 166.) With potassium dichromate and concentrated sulphuric acid it turns a dark red; with the potassium salt alone, a deep yellow-orange; with neutral iron chloride, an amethyst color.

A delicate test proposed for the detection of apomorphine is as follows: To 5 cc. of apomorphine solution add 5 drops of a saturated solution of mercuric chloride followed by 5 drops of a 10 per cent. sodium acetate solution. Boil for a minute and when cool add 1 cc. of amyl alcohol and shake. The amyl alcohol acquires a blue coloration in solutions of as little as 2 parts to the million of apomorphine.

According to Harnack and Hildebrand (*A. E. P. P.*, 1911, lxv, p. 38) apomorphine hydrochloride is sometimes contaminated with *chloromorphine,* whose action is very similar to that of acetyl-morphine. Frerichs (*P. J.*, lxxxiv, p. 293) reports having examined two samples of apomorphine hydrochloride which consisted almost entirely of *trimorphine hydrochloride.*

Uses.—Apomorphine hydrochloride was first brought forward by Gee as a prompt and efficient emetic. According to the researches of Eggleston and Hatcher (*J. P. Ex. T.*, 1912, iii, p. 551) the vomiting is due solely to an action on the vomiting center. Aside from its emetic effects, therapeutic doses of apomorphine ordinarily have very little influence upon the system. Rosenwasser (*N. Y. M. R.*, July, 1907), however, and some other writers maintain that it has narcotic properties, but it is not impossible that the effects they have observed have been due to impurities in the drug. It has the great advantages of smallness of dose and freedom from irritating properties, so that it can be used hypodermically. When from one-fifteenth to one-tenth of a grain (0.004–0.006 Gm.) of it is injected under the skin of a man, free emesis usually occurs in from 5 to 20 minutes. The effects upon the general system are usually not marked; but in some cases very alarming syncopal symptoms have been produced, and death is said to have resulted from one-sixteenth of a grain (0.004 Gm.) in a feeble adult worn out with chronic bronchitis and emphysema. (*Med. Rec.*, 1877, p. 664; see also Seuffer, *M. M. W.*, 1921, xix, p. 584.) Apomorphine hydrochloride is a very useful emetic in cases of *poisoning* or *acute gastritis* or any other condition where it is desired to promptly evacuate the stomach. Its advantages are, first, lack of irritation of the gastric mucosa, secondly, the smallness of dose which makes it possible to carry it in the form of a hypodermic tablet, and thirdly, the promptness of its effect. In cases of *narcotic poisoning,* however, it frequently fails to act, because of the depression of the vomiting centers. Given in doses too small to act as an emetic it is a valuable nauseating expectorant in the early stages of *acute bronchitis.* One drawback to its wider use for this purpose is its instability when in solution. The green substance formed does not seem to be toxic, but it does not possess the peculiar therapeutic properties of the drug. Under no circumstances should more than one-fourth of a grain (0.016 Gm.) by mouth, or one-eighth of a grain (0.008 Gm.) hypodermically, be given at a dose.

Dose, as an expectorant, one-thirtieth to one-twentieth of a grain (0.002–0.003 Gm.); as an emetic, one-fifteenth to one-eighth of a grain (0.004–0.008 Gm.).

Off. Prep.—Injectio Apomorphinæ Hypodermica, *Br.*

AQUA. U. S.

WATER

"Natural water (H_2O), conforming to the following description and tests." *U. S.*

Eau, *Fr.;* Wasser, *G.;* Acqua, *It.;* Agua, *Sp.*

Water has always been included in the U. S. Pharmacopœia, on account of its great importance as a medicinal and pharmaceutical agent. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a substance of such diversified agency, our limits will allow of a sketch only of its properties and modifications. We shall speak of it under the several heads of *pure water, common water,* and *mineral waters.* For description of distilled water, see under *Aqua Destillata.*

Pure Water.—Water, in a pure state, is a transparent liquid, without color, taste, or odor. Its sp. gr. is assumed to be unity, and forms the term of comparison for that of solids and liquids. A cubic inch of it, at the temperature of 15.5° C., weighs very nearly 252.5 grains; when weighed in air with brass weights at 25° C. it weighs 251.91 grains. In the metric system the weight of 1 cc. of distilled water taken at 4° C. is made equal to 1 gramme, the unit of weight in this system. Water is compressible to a small extent, as was proved first by Canton, and afterwards, in an incontestable manner, by Perkins. Reduced in temperature to 0° C., it becomes a solid or ice, with the sp. gr. 0.9175; and raised to 100° C. an elastic gas called steam. In the latter state its bulk is increased nearly 1700-fold, and its sp. gr. so far lessened as to be not much more than half that of atmospheric air. At the temperature of 4° C., its density is at the maximum; and consequently, setting out from that point, it is increased in bulk by being either heated or cooled. It has the power of dissolving all gases, to a greater or lesser extent, including the constituents of common air, which are always present in natural water in variable proportions. It invariably exists in the atmosphere, in the form of invisible vapor.

Common Water.—By reason of its extensive solvent powers, water, in its natural state, must be more or less contaminated with foreign matter. Thus, it becomes variously impregnated, according to the nature of the strata through which it percolates. When the foreign substances present are in so small an amount as not materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water.*

There are almost innumerable shades of difference in common water, as obtained from different localities and sources; but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but little dissolved matter, particularly compounds of calcium and magnesium, and which, when used in washing, readily forms a lather with soap. By a *hard water* is understood a variety of water which contains calcium or magnesium salts, through which it curdles soap by forming insoluble compounds with the fatty acids, and is often unfit for domestic purposes. Solution of soap is a good test liquid for ascertaining the hardness of water. In distilled water it produces a very slight opalescence, due to the hydrolysis of the soap; in soft water, only a slight opalescence; but in hard water, a milky appearance or a curdy precipitate which is due to the formation of an insoluble compound between the fatty acids of the soap and the calcium or magnesium compounds. The hardness may be classed as temporary or permanent. Temporary hardness is observed in waters which contain much free carbon dioxide; the hardness is removed or diminished by boiling, which causes a loss of the gas and a deposition of the calcium and magnesium salts which produce the hardness and which have been held in solution as bicarbonates. Permanent hardness is caused by the presence of calcium sulphate or by calcium or magnesium chlorides which are not removed by boiling and filtering. The hardness may be estimated by means of a volumetric soap solution which is added in small quantities to a measured quantity of the water, shaking after each addition and noting the volume of the soap solution which is required to produce a lather which will remain on the surface for five minutes. The hardness is usually expressed in parts of calcium carbonate per 100,000 in the water.

The most usual foreign substances in solution in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbon dioxide, calcium sulphate, calcium and magnesium carbonate, and sodium chloride. Carbon dioxide is detected by lime water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off the carbon dioxide. The presence of calcium sulphate is shown by precipitates being produced by barium chloride, and, after ebullition, by ammonium oxalate. The former test shows the presence of sulphate, and the latter, after boiling the water, indicates lime not held in solution by carbon dioxide. Calcium carbonate when held in solution by an excess of carbon dioxide, may be detected by boiling the water, which causes it to precipitate; but even after ebullition and filtration the water will retain enough calcium carbonate to give a precipitate with lead acetate, calcium carbonate being itself to a minute extent soluble in water. Silver nitrate will produce a precipitate if any soluble chloride be present; and, ordinarily, the one present may be assumed to be common salt. Small amounts of iron and aluminum salts and silica are almost always found in potable waters.

Clark has proposed to purify hard water, when the hardness arises from calcium bicarbonate, by a process which he calls *liming*. This consists in adding to the water sufficient lime water to convert the bicarbonate into the very sparingly soluble carbonate. This procedure renders the water soft, and gets rid of all the lime, except that in the minute portion of carbonate dissolved. The merit of this process consists chiefly, not in the removal of lime, but in preventing the formation of organic growths, principally confervæ, the decomposition of which renders the water offensive and unwholesome. River water containing the usual amount of calcareous matter, if allowed to stagnate in open reservoirs, in the summer, will become contaminated with myriads of microscopic plants and animals. This change is prevented, according to Clark, by his peculiar treatment, which deprives the living organisms of the nutriment derived from loosely combined carbon dioxide. A more modern method of softening water is to pass it through a filter composed of certain alkaline silicates, either natural or artificial, called *zeolites*. After the filter has lost its power of water softening it may be quickly and easily regenerated by passing through it a solution of sodium chloride.

The oxygen and nitrogen present in neutral waters are not usually in the same proportion as in atmospheric air; the oxygen in atmospheric air amounts to about 20 per cent. in volume, while the usual gaseous mixture expelled from fresh water by boiling contains over 30 per cent. (See table on page 161.) The important discovery has been made by Moore and Kellerman of the U. S. Department of Agriculture, that copper sulphate, if present in amounts such as 1 in 4,000,000 will be toxic to algæ, destroying them and preventing their reappearance; this statement has been confirmed by Gildersleeve (*Am. J. M. S.*, 1905, 129, p. 757), Stewart (*Am. J. M. S.*, 1905, p. 761), Kraemer (*A. J. P.*, 1906, 140), and others. They state that one part of copper sulphate in 100,000 of water will destroy typhoid and cholera germs in from three to four hours, and it appears to be established that waters not containing too large amounts of organic matter, exposed to the action of copper foil, kept in copper vessels, or treated with small amounts of copper sulphate (1 to 500,000), will destroy all typhoid bacilli and many other organisms in from 3 to 6 hours. On the other hand as shown by Doty (*N. Y. M. R.*, cxvii, p. 90), and Fowler (*Jour. Roy. Army Med. Corps,* 1905, v, 391), in the presence of even moderate quantities of organic matter the bactericidal power of copper is much reduced, while in foul waters it is almost nil. See Henry Kraemer. (*A. J. P.*, 1905, p. 265.)

Common water is also divided into varieties according to its source. Thus, we have rain, snow, spring, river, well, lake, and marsh water.

Rain (*aqua pluvialis*) and *snow water* (*aqua nivalis*) are the purest kinds of natural water. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields, at a distance from houses, and some time after the rain has commenced falling; otherwise it will be contaminated with the dust which floats in the atmosphere, and with other impurities derived from roofs. The rain water of large cities contains nitrogenized organic matter, as shown by the odor produced by burning the residue left after the water has been evaporated. In districts near the sea coast rain water usually contains appreciable quantities of chlorides.

Rain water ordinarily contains atmospheric air, and, according to Liebig, a little nitric acid, the amount of which is increased when the rain descends during a thunder storm. Chabrier states as the result of his observations that rain water contains either nitrous or nitric acid, the one or the other predominating according to the condition of the weather, the nitrous acid being relatively in excess in mild weather, but the nitric when the rain is attended with tempestuous winds. According to an analysis, made by Martin, of rain water which fell at Marseilles during a violent storm, 1000 parts by weight contained 0.004 of chlorine and 0.003 of ammonia. Not a trace of iodine or of nitric acid was discovered. Boussingault has ascertained that the rain which falls in towns contains considerably more ammonia than that which falls in the country. Thus the rain of Paris was found by him to contain three or four parts of ammonia per million, while that collected in a mountainous region contained about four-fifths of one part only in a million. The average results of J. B. Lawes and J. H. Gilbert give one part of ammonia to the million of rain water. Snow water has a peculiar taste, which was supposed to depend on the presence of air more oxygenated than that of the atmosphere; but in point of fact it contains no air, and this accounts for its vapid taste. Rain and snow water are sufficiently pure for most chemical operations.

Spring water (*aqua fontana*) depends entirely for its quality on the strata through which it flows, being purest when it passes through silicious sand or gravel, or where the prevailing rock formation is granitic. On the contrary, where the formation is limestone, the water will, because of the carbon dioxide dissolved in it, take up calcium carbonate, convert it into a bicarbonate, and become what is called a *hard water.* It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River water (*aqua fluvialis*) is, generally speaking, less impregnated with saline matter than spring water, because made up in considerable part of rains, while its volume bears a larger proportion to the surface of its bed. It is, however, much more apt to have mechanically suspended in it insoluble matters, of an earthy nature, like clay and silt, which impair its transparency. It is frequently rendered more sightly by being run through porous stone, carbon, or sand filters. The coarse particles are removed by this filtration; but sewage or injurious products resulting from decomposition which are dissolved in the water are not removed, so that such clean filtered water may be deleterious to health. Water may be purified for manufacturing purposes by what is termed the alum process,—*i.e.,* by adding 2 grains of alum to a gallon of water, and permitting the impurities to subside for 48 hours. (*Chem. News,* July 23, 1886.) River water is purified now at many cities on the large scale by filtration through sand. (See *U. S. D.,* 19th ed., p. 163.)

Well water, like that from springs, is liable to contain various impurities. As a rule, the purity of the water of a well will be in proportion to its depth and the constancy with which it is used. Well water in large cities always contains a large amount of impurity, both organic and inorganic, the result of sewage contamination. The presence of nitrates in water is destructive to many forms of organic life. *Artesian Wells,* from their great depth, generally afford a pure water, although on analysis they frequently show a larger proportion of solid constituents on evaporation than do waters from rivers.

Lake water cannot be characterized as having any invariable qualities. The water of most of the lakes in the United States is pure and wholesome except where it is near large centers of population, when it is usually contaminated by sewage.

Marsh water is generally stagnant, and contains vegetable matter undergoing decomposition. It is unwholesome, and ought never to be used internally.

All water which is exposed to the air dissolves a quantity of oxygen, nitrogen, and carbon dioxide, in obedience to the laws of gaseous absorption. It is indeed upon this dissolved oxygen that the life of water-breathing animals depends. In every pure water the proportion between the dissolved nitrogen and oxygen is found to be constant, and it is represented by the following numbers:—oxygen 34.91, and nitrogen 65.09 per cent.; 1000 parts of pure water, such as rain water, when saturated dissolves 17.95 parts of air. If the water be rendered impure by the introduction of organic matter undergoing oxidation, the proportion between the dissolved oxygen and nitrogen becomes different, owing to the oxygen having been partly or wholly used for the oxidation of this material.

The measurement of this condition is accomplished by determining what is known as its oxygen consuming power which depends upon the amount of potassium permanganate which is reduced under specified conditions.

The second class of dissolved impurities consists of inorganic salts, even rain water washing some of these out of the atmosphere. It invariably contains ammonium salts, sodium chloride, and particles of organic matter, living and dead. In towns the rain water also contains a larger proportion of nitrates than that falling in the country. It is, however, the spring waters especially which contain the largest amount of mineral matter in solution. The salts which most commonly occur in solution in spring water are: (1) Calcium, magnesium, iron, and manganese carbonates, dissolved in an excess of carbon dioxide. (2) Calcium and magnesium sulphates. (3) Alkaline carbonates, chlorides, sulphates, nitrates, or silicates.

Spring waters which issue from considerable depths, or which originate in volcanic districts, are always hotter than the mean annual temperature of the locality where they come to the surface.

Properties.—The term *Aqua,* in the United States Pharmacopœia, may be considered as designating any natural water of good quality which answers well for cooking and does not curdle soap.

Description and Physical Properties.—"A colorless, limpid liquid, practically tasteless and odorless.

"Water is neutral to litmus paper. When heated nearly to the boiling point and agitated, no disagreeable odor is evolved. The residue obtained upon evaporating 100 cc. of Water in a platinum dish does not exceed 0.03 Gm. (*solids*), and this residue, when carefully heated to redness, evolves no visible fumes and shows no appreciable charring (*organic impurities*). Add 1 cc. of hydrochloric acid to 100 cc. of Water and then add 50 cc. of hydrogen sulphide T.S.: no darkening occurs after standing for fifteen minutes (*lead or copper*). Add 1 cc. of hydrochloric acid to 100 cc. of Water and then add 1 cc. of potassium ferrocyanide T.S.: no blue coloration is produced immediately (*iron*). Add 0.5 cc. of tenth-normal silver nitrate to 200 cc. of Water, heat to boiling, filter, and add to the filtrate 3 drops of potassium chromate T.S.: a red precipitate is produced (*limit of chloride*). Add successively 1 drop of acetic acid, 1 cc. of sulphanilic acid T.S., and 1 cc. of naphthylamine acetate T.S. to 100 cc. of Water in a Nessler tube, stirring with a glass rod after each addition. Closely cover the tube with a glass plate, place it upon a white surface, and view it from above: no pink coloration appears within five minutes (*nitrite*). Add 1 cc. of sodium carbonate T.S. to 100 cc. of Water, and evaporate the liquid in a small porcelain dish just to dryness. Moisten the residue thoroughly with 2 cc. of phenoldisulphonic acid T.S., gently warm the dish, add 20 cc. of ammonia T.S. and sufficient distilled water to measure 100 cc. Any yellow color produced is not greater than that obtained by evaporating 0.0021 Gm. of potassium nitrate, dissolved in 3 cc. of distilled water and 1 cc. of sodium carbonate T.S., to dryness and treating the residue in the same manner as the residue from the Water. The comparison of colors must be made in Nessler tubes of the same diameter and size (*nitrate*). Add 2 cc. of alkaline mercuric potassium iodide T.S. to 100 cc. of Water in a Nessler tube, and mix thoroughly. Place the tube on a white surface, and view the contents from above: the water does not at once assume a deep yellow or orange color (*ammonium salts and nitrogenous impurities*). Mix 100 cc. of Water with 10 cc. of diluted sulphuric acid in a clean porcelain dish, and heat it rapidly to boiling, then add 0.4 cc. of tenth-normal potassium permanganate, and boil the liquid for ten minutes: the color of the liquid is not completely destroyed (*oxidizable substances*)." *U. S.*

The British Pharmacopœia no longer includes *"Aqua"*; it recognizes *"Aqua Destillata,"* and gives appropriate tests.

Water should never be allowed to stand in contact with leaden pipes, etc., on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to the softness and purity of the water; for it is found that the presence of a minute proportion of saline matter, as for example of calcium sulphate, protects the water from the slightest metallic impregnation. This result is produced by the formation of a thin film of insoluble lead sulphate upon the surface of the metal, thus preventing further action. The chlorides are not protective, as they give rise to lead chloride, which is slightly soluble. Upon this principle is based a plan of protection by Schwartz of Breslau, who proposes to fill leaden pipes through which water is conducted, with a strong solution of an alkaline sulphide, which forms a perfectly insoluble coating of lead sulphide (*sulphuret*), said to be quite impermeable by the water afterwards introduced. Galvanized iron (zinc coated) does not corrode as readily as iron which is unprotected, because as the zinc has the greater solution tension it protects the iron, which remains unacted upon; galvanized iron pipes are, however, attacked by water containing much free CO_2. On the other hand, tinned iron (tinplate) corrodes more readily than iron alone if the iron is exposed at any point; the iron being the anode end is at once attacked. The action of water upon various metals has been exhaustively studied by Jorissen (*Internat. Pharm. Cong.*, 1914, 696) who found that aluminum was but slightly affected by distilled water; ordinary water acted upon it decidedly, producing crater-shaped corrosions. Magnalium (an alloy of magnesium and aluminum) is less liable to corrosion. Copper is only slightly affected by distilled water; sea water, free from air, does not act upon copper, but in the presence of air, corrosion readily occurs with formation of carbonates and chlorides. Lead is affected by water which is free from CO_2, especially when dissolved oxygen is present. The presence of CO_2 considerably lowers the percentage of dissolved lead. Nickel is not corroded even by sea water; over 35 per cent. of nickel will prevent iron from rusting. Tin is proof against the action of distilled water. Ordinary water acts upon it slightly. Sea water containing air acts upon it at first, but it is soon protected by a layer of basic salts. Zinc in distilled water free from CO_2 and oxygen preserves its shining surface for years. When oxygen is present zinc hydroxide is produced, which is slightly soluble, and when CO_2 is present, a slightly soluble carbonate is also formed.

A very important class of dissolved impurities is made up of organic compounds. This organic matter may be derived from a vegetable source, such as leaf-mould and the decomposition products of wood, in which case it is practically harmless, or it may be derived from animal sources, in which case it almost always proves a serious impurity.

The careful observations of students of public health leave no doubt that a number of epidemic diseases, especially cholera and typhoid fever, are often contracted and spread by means of drinking water contaminated with germs of disease from excreta and general sewage. This impure water may be clear and may have filtered through considerable distances of soil, and yet may contain these poisonous germs. Now, nitrogen is one of the characteristic constituents of animal matter as contrasted with vegetable matter, relatively few forms of which contain it, and those are of a character not likely to be found in natural waters. Hence, if water should be impregnated with animal matter, this would be indicated by the presence of nitrogen in solution, either in the form of albumin or albuminous matter, if the animal matter in the water is still unchanged, or, if the animal matter has undergone oxidation, in the form of ammonia or nitrous or nitric acid.

There are, therefore, to be determined in this presence of organic nitrogenous matter, (1) the examination of a water with reference to the free ammonia, (2) the unchanged albuminous matter, which, as it is changed into and determined as ammonia, is called "albuminoid ammonia," and (3) the nitrates and nitrites present.

The free ammonia is first determined by distilling the water made alkaline with sodium carbonate as long as the distillate carries enough ammonia to be recognized by *Nessler's solution.* (See Part III.) For this purpose the distillate is collected successively in volumes of 50 cc. and the amount of ammonia in each of these separate distillates determined. The smallest quantity of ammonia will produce a yellow color, the tint of which is to be compared with that obtained from the Nessler solution treated with a standard ammonium chloride solution.

After the free ammonia has been distilled off, a solution of sodium hydroxide and potassium permanganate is added and the distillation is continued. Another portion of ammonia now comes off, owing to the action of the permanganate on the nitrogenous organic matter. The amount of ammonia thus obtained is determined, and is tabulated as "albuminoid ammonia," because albumin is one of the bodies which is decomposed in this way. L. de Konnick found that the Nessler test in ammonia liquids does not produce the usual yellowish-brown precipitate, nor even a coloration, in the presence of alcohol. (*Am. Drug.,* 1893, p. 386.)

Instead of this method proposed by Wanklyn and Chapman, another process, described by Frankland and Armstrong, is often used. In this case, the water having been evaporated, the dry residue is submitted to an organic combustion analysis, which gives the "organic nitrogen" and the "organic carbon," and the ratio of these gives an indication as to the presence of albuminous matter rich in nitrogen. If the amount of albuminoid nitrogen indicated by either of these processes exceeds 0.15 part for one million of water, the latter should be rejected as a drinking water. In some large towns, however, the surface well waters have shown albuminoid nitrogen to the amount of 0.3 to 0.8 part per million. Such waters are little better than sewage. The free ammonia, moreover, should not exceed 0.08 part per million, or the water must be considered as containing sewage contamination.

Nitrates may be estimated by the following process. A measured volume (15–25 cc.) of the water is evaporated just to dryness in a flat-bottomed porcelain dish, 1 cc. of phenoldisulphonic acid (made by heating 37 grammes of strong sulphuric acid with 3 grammes of pure phenol for 6 hours in a water bath) is added and thoroughly mixed with the residue by means of a glass rod. It is then diluted with about 25 cc. of water, solution of ammonium hydroxide added in excess and the volume of the solution made up to 50 cc. The nitrates present in the residue convert the phenoldisulphonic acid into picric acid, which, by the action of ammonium hydroxide forms ammonium picrate; this imparts to the solution a yellow color which is proportional in its intensity to the amount of nitrates present in the water, and by carrying out a similar test with a standard solution of potassium nitrate similarly evaporated, the amount may be accurately estimated. Nitrites may be estimated by the sulphanilic acid and naphthylamine hydrochloride test given for the qualitative detection of nitrites by the U. S. Pharmacopœia, by carrying out a similar test with a standard solution of sodium nitrite and making a comparison of the relative intensity of the color which is produced in each.

The determination of chlorides is also frequently of great importance, for although mineral waters may be rich in chlorides, ordinary well waters or river waters, which are the chief sources of supply, will not contain much chlorine unless they have been contaminated. Both urine and sewage may contribute this chlorine, as they are highly charged with sodium chloride. As a rule, it may be said that water containing more than two grains of chlorine per gallon must be looked upon with suspicion, unless some good reason for the presence of sodium chloride can be assigned. According to some authorities the amount of chlorine should not be over 10 per cent. of the total solids found in the water by evaporation.

MINERAL WATERS.—When natural spring waters are so far impregnated with foreign substances as to have a decided taste, and to operate in a peculiar manner upon the human economy, they are called *mineral waters.* There has been an enormous amount of fraud perpetrated in connection with the mineral waters. The so-called natural "lithium waters" contain only traces of that element and a number of them have been proven misbranded within the meaning of the Food and Drugs Act. Mineral waters are conveniently arranged under the heads of *carbonated, alkaline, sulphuretted, saline* (including *magnesian, chalybeate,* and *chlorinated*), and *siliceous.* For a more comprehensive and detailed classification of this class of waters see *Mineral Waters of the United States,* U. S. Department of Agriculture, Bulletin No. 91.

1.—*Carbonated waters* are always cold, as they issue naturally from the earth and are characterized by containing an excess of carbon dioxide, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain calcium, magnesium, and iron, which are held in solution by the excess of carbon dioxide as bicarbonates. The waters of Seltzer, Spa, Apollinaris, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class. For Artificial Carbonic Acid Water, see page 162.

2.—*Alkaline waters* contain a large quantity of sodium bicarbonate or carbonate, as well as common salt and Glauber's salt. These are sometimes warm, such as the springs at Ems and Vichy, but generally cold. Gettysburg spring water is of this class.

3.—*Sulphuretted waters* are such as contain hydrogen sulphide, and are distinguished by the peculiar fetid odor of that gas, and by yielding a brown precipitate with the salts of lead or silver. Examples of this kind are the waters of Aix-la-Chapelle and Harrogate in Europe, and those of the White, Red, and Salt sulphur springs in Virginia. Sulphuretted waters are not marketable without deterioration as the gas is very fugitive and easily oxidizable in dilute solutions.

4.—*Saline waters* are those the predominant properties of which depend upon saline impregnation. The salts most usually present are sodium, calcium, and magnesium sulphates and carbonates, in which latter case the name *magnesian* is given to them, the presence of the chlorides of these alkalies making the class *chlorinated waters,* which reach their maximum concentration in sea waters; while the presence of ferrous salts makes another class, the *chalybeate.* Among magnesium waters may be mentioned those of Friedrichshall, Hunyádi Janos, and Epsom; among chalybeate waters, those of Tunbridge and Brighton in England, of Pyrmont, Wiesbaden, and Spa on the Continent, and of Bedford, Pittsburg, and Brandywine in the United States. Potassium sulphate is occasionally present, and lithium has been detected by Berzelius in Carlsbad and other salt springs of Germany, and is also found in some American spring waters. Boric acid, usually in the form of an alkaline borate, is of frequent occurrence in mineral waters of certain portions of the United States. Cæsium and rubidium have also been detected in certain mineral waters, such as the Dürkheim and Baden-Baden waters, in the former of which these elements were first discovered by Bunsen. Bromine is found in the saline at Theodorshalle, in Germany, as also in the salt wells of western Pennsylvania, Ohio, Michigan, and West Virginia. The mineral springs at Saratoga contain a small proportion of iodine and bromine . The principle saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and Harrodsburg and Saratoga in the United States.

Arsenic in minute quantity has been found in some waters used as drink. At Whitbeck, in Cumberland, England, the inhabitants employ, both as drink and for culinary purposes, a water holding enough arsenic in solution to be quite sensible to tests, without any known injurious consequences.

5.—*Siliceous waters* are those in which the contents consist chiefly of alkaline silicates, such as the hot spring waters of Iceland and the geysers of Fire-hole Basin and Gardiner's River, Yellowstone National Park, U. S.

6.—*Sea Water:* The water of the oceans differs from most inland waters chiefly in containing a larger amount of dissolved salts, especially sodium chloride. The composition of ocean water differs in various parts of the world. Generally spaking, it is less concentrated near the shores because of the influence of fresh water rivers. The following is an analysis of the water in the English Channel ten miles from the coast of France (*J. P. C.,* 1865, i, p. 381) which had a specific gravity of 1.026 at 15° C.

Further out from shore the proportion of sodium chloride may rise to 36 or 37 parts per thousand.

In inland seas the proportion of salt is often very much greater than that of the ocean, thus the amount of solids in the water of the Great Salt Lake of Utah has varied between 15 and 20 per cent. while in the Dead Sea of Palestine there is 27 per cent. of solids. Besides these ingredients, others are alleged to exist in minute proportion in sea water, as fluorine by G. Wilson; lead, copper, and silver by Malaguti, Durocher, and Sarzeau; and iron and manganese by Uziglio. Gold in very minute quantities has been found in sea water. Prior to Wilson's researches, Middleton and Silliman, Jr., had inferred the existence of fluorine in sea water, from its presence in marine animals. The lead and copper above mentioned were found in certain fuci only, the silver in the sea water itself. The presence of silver in sea water has been demonstrated by F. Field, by a comparative analysis of the same copper sheathing, when new, and after having been on a vessel for many years. Schweitzer's analysis gives a small proportion of calcium carbonate, but Bibra could not detect any. John Davy's examinations of sea water show that calcium carbonate does not exist at a great distance from land, except in very minute proportion, but becomes quite evident at a distance of from fifty to a hundred miles from coasts. Boric acid has been found by Veatch in the sea water on the coast of California. (See *A. J. P.*, 1860, p. 330.)

Sea water, filtered, and charged with five times it volume of carbon dioxide, forms, according to Pasquier, a gentle purgative, which keeps very well, and is not disagreeable to take. The dose is from half a pint to a pint.

By freezing, sea water is almost entirely freed from saline matter, the ice being nearly pure water. It is obvious that the unfrozen water contains much more than its ordinary proportion of salts; and this is one of the methods of concentrating this and other saline solutions.

Medicinal Properties of Water.—Water is a remedy of great value in a large number of complaints either internally or externally. When taken internally, cold water, below 10° C., inhibits the secretion of the digestive juices and therefore delays digestion. If at a temperature of from 15° to 21° C. it is almost without effect; the elaborate studies of Hawk (*J. Am. C. S.*, 1911, xxiii, and 1912, xxxiv) have completely dissipated the old superstition that water lowered digestive activity by diluting the ferment in the stomach. At tepid temperatures, 26° to 32° C., it is likely to nauseate, and if taken in large quantities may even produce emesis. After its absorption water has a profound influence in increasing all the bodily secretions, notably those of the kidney and sweat glands. It is therefore frequently used as a diuretic when it is desired either to wash out toxic substances from the system or, by dilution, to make an irritating urine more bland. Carr (*J. P. Ex. T.*, 1921, xviii, 221) has found that the drinking of large amounts of water tends to increase the elimination of urea and sulphates and to decrease the acidity of the urine but that the excretion of creatinin and phosphates is not affected. In conjunction with external heat, or diaphoretic drugs, it is also of much service to increase the perspiration in various morbid conditions. When the systemic effects of water are desired quickly it may frequently be given advantageously in the form of salt solution, either hypodermically or intravenously. (See *Liquor Sodii Chloridi Physiologicus.*) Although a very potent agent for good in proper cases it should not be forgotten that the too free drinking of water may prove harmful, especially in patients with feeble heart muscle.

Externally, although occasionally useful for the purpose of softening the skin, water is mostly applied as a means of conveying other medicinal forces either chemical, thermal or mechanical. Over small areas it may be applied either very hot, 49° to 60° C., or ice cold, for its counter-irritant effect in various internal inflammations. The use of hot and cold baths has become one of the most important methods of treatment, and for consideration of the subject the reader is referred to text-books on hydrotherapy.

Frequently various chemicals are added to increase the effects of the bath. Of these forms of saline baths the most important is the so-called *Nauheim* or *carbonated baths.* For this purpose a naturally effervescent springs, Bad Nauheim in the Grand Duchy of Hesse, was originally used. *Artificial Nauheim baths,* however, have been widely employed. For this purpose the following formula may be used: In one package a mixture of sodium carbonate 1½ pounds, sodium bicarbonate ½ pound, calcium chloride 3 pounds, sodium chloride 2 pounds. This is dissolved in the bath of about 50 gallons, and then afterward 1 pound of sodium bisulphate is added slowly. This bath is used chiefly in the treatment of certain forms of *heart disease.* Another and very old bath which is used both as a diaphoretic and as a stimulant in various forms of *shock,* especially in young children, is the *mustard bath,* which is made by adding ground mustard in the proportions of 1 or 2 ounces for each gallon of water.

AQUA ACIDI CARBONICI, *Carbonic Acid Water,* or *Soda Water* (so called), (*Eau gazeuse simple,* Fr.; *Kohlensaurewasser,* G.), which was formerly official in the U. S. Pharmacopœia, consists of water highly charged with carbonic acid.

Preparation.—Water is found to take up its own volume of this gas under the pressure of the atmosphere; and Henry ascertained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. From the principles above laid down it follows that, to saturate water with five times its volume of carbon dioxide, it must be subjected to a pressure of five atmospheres. Carbonic acid gas compressed into the liquid state is now manufactured on an immense scale and supplied in 20-pound and 50-pound steel cylinders. This allows of convenient transportation, and the purity of the gas is usually excellent.

Carbonic acid water is familiarly called in this country *"mineral water," "plain soda,"* and *"soda water"*; the latter names originally applied to the preparation when it contained sodium carbonate, being from habit continued since the alkali has been omitted.

Carbonic acid water is dispensed in most of the pharmacies in this country. The reservoir, called the "fountain," is sometimes placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the store, and to terminate in a draught tube, by means of which the carbonic acid water may be drawn off at pleasure. In other and more modern devices the cylinder of compressed carbon dioxide is attached in such a manner to the reservoir that the water is continuously and automatically carbonated until the cylinder is exhausted. In order to have the liquid cool, the tube from the carbonating device or the "fountain" generally terminates in a strong metallic vessel of convenient shape, or a series of block tin pipes called coolers, placed inside the counter apparatus, and surrounded with ice.

Properties.—Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus and produces a precipitate with lime water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when the pressure is released by drawing it into an open vessel. Hence, to preserve its sparkling qualities, it should be kept in strong vessels or in strong, well-corked bottles placed inverted in a cool place. Several natural waters contain an excess of carbonic acid, such as those of Seltzer, Spa, Pyrmont, Apollinaris, etc., but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the reservoir and tubes well protected on the inner surface. Iron fountains lined with a hard enamel are preferred to those of copper, but the best fountains are made of cast steel, lined with block tin. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. Tubes of pure tin are free from objection, and are now almost exclusively used.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting the interior, owing to the solder joint which permanently unites the two sections of the fountain. There can be no doubt that carbonic acid water is sometimes rendered poisonous by metallic impregnation. R. O. Doremus has proved by a chemical examination that lead and copper are sometimes present. Lead is detected by hydrogen sulphide, which gives with it a black precipitate, and copper by potassium ferrocyanide, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper, when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid. Fortunately copper fountains have largely gone out of use, having been supplanted by those made of steel.

Uses.—Carbonic acid water is a grateful drink to *febrile patients,* allaying thirst, lessening *nausea* and *gastric distress,* and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, magnesium sulphate, and the saline cathartics generally, rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces (180–240 cc.) will be sufficient.

AQUA AMMONIÆ. U. S. (Br.)

AMMONIA WATER Aq. Ammon. [Solution of Ammonium Hydroxide]

"Ammonia Water is an aqueous solution of ammonia (NH_3) containing not less than 9.5 per cent. nor more than 10.5 per cent. by weight of NH_3. This solution deteriorates rapidly, and must be assayed frequently." *U. S.* "Solution of Ammonia is an aqueous solution containing 10 per cent. by weight of ammonia, NH_3." *Br.*

Liquor Ammoniæ, *Br.;* Solution of Ammonia; Water of Ammonia; Spiritus Salis Ammoniaci Causticus; Ammonium Hydroxide Solution; Ammonium Causticum; Alkali Volatile; Ammoniaque officinale, *Fr. Cod.;* Eau (Liqueur) d'Ammoniaque, *Fr.;* Liquor Ammonii Caustici, *P. G.;* Salmiakgeist, Aetzammoniak, Ammoniak-Flüssigkeit, *G.;* Ammoniaca, *It.;* Amoniaco, Amoniaco liquido, *Sp.*

The U. S. Pharmacopœia X gives no process for preparing Ammonia Water. The U. S. P., 1870, contained an excellent process, which is as follows: "Take of Chloride of Ammonium, in small pieces, Lime, each, *twelve troyounces;* Water, *six pints;* Distilled Water, *a sufficient quantity.* Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Chloride of Ammonium. Place the retort on a sand-bath, and adapt to it a receiver purposely connected with a two-pint bottle, by means of a glass tube, reaching nearly to the bottom of the bottle, and containing a pint of Distilled Water. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0.960. Lastly, keep the liquid in small bottles, well-stoppered."

"Strong Solution of Ammonia, 500 millilitres; Distilled Water, 1000 millilitres. Mix." *Br.*

In the U. S. P., 1870, process the ammonium chloride is decomposed by the superior affinity of the calcium for the chlorine, ammonia is disengaged, and calcium chloride and water are formed.

$$2NH_4Cl + Ca(OH)_2 = CaCl_2 + 2H_2O + 2NH_3$$

The British Pharmacopœia gives directions for diluting *Liquor Ammoniæ Fortis* so as to reduce it to the strength of *Liquor Ammoniæ.* This is effected by mixing one measure of their stronger preparation with two measures of distilled water. The ammonia water of commerce is sometimes known as 'Aqua Ammoniæ F. F. F.," or "20° ammonia"; corresponding to about 16 per cent. of NH_3; it may be diluted by adding 2 volumes of water to 4 volumes of 20° ammonia water to make official ammonia water. Ammonia water of other strengths may be diluted by consulting the table given in Part III, and applying the rules given in Remington's *Practice of Pharmacy.*

Ammonia water of the various commercial strengths is one of the few substances which continue to be designated by strength in terms of the specific gravity expressed in degrees Baumé. Thus *"16° ammonia"* is equivalent to 10 per cent., and *"26° ammonia"* is equivalent to 28 per cent.

Description and Physical Properties.—"A colorless, transparent liquid, having a very pungent, characteristic odor. Specific gravity: about 0.958 at 25° C. Ammonia Water is strongly alkaline to litmus paper. Dense, white fumes are produced on bringing a glass rod dipped into hydrochloric acid near the surface of the Ammonia Water.

"A 25 cc. portion of Ammonia Water, evaporated to dryness in a platinum or porcelain dish and dried to constant weight at 120° C., leaves not more than 0.005 Gm. of residue. Add 0.1 cc. of tenth-normal potassium permanganate to 10 cc. of Ammonia Water to which a slight excess of diluted sulphuric acid has been added: the pink color is not completely destroyed within ten minutes (*oxidizable substances*). When neutralized and then made slightly acid with hydrochloric acid, a 10 cc. portion of the Water meets the requirements of the test for *heavy metals,* page 439.

"**Assay.**—Pour into a weighing bottle about 10 cc. of distilled water, tare the bottle and its contents, add about 5 cc. of Ammonia Water, and weigh accurately. Then titrate with normal sulphuric acid, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

"Preserve in a cool place in glass-stoppered or rubber-stoppered bottles made of hard glass, free from lead." *U. S.*

"Specific gravity 0.959. 3 grammes require for neutralisation 17.6 millilitres of *N/1 solution of sulphuric acid.* Responds in other respects to the tests and possesses the general characters described under 'Liquor Ammoniæ Fortis.'" *Br.*

Commercial solution of ammonia sometimes contains pyrrol, naphthalene, aniline, and pyridine. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with hydrochloric acid, by its tingeing a slip of fir wood a rich purple color, characteristic of pyrrol. (Maclagan.) The source of these impurities is coal gas liquor, from which the ammonia compounds are largely obtained. Donath (*Dingler's Polytechnisches Journal,* vol. iv, p. 229) tested some ammonia prepared from gas liquor, by neutralizing with diluted sulphuric acid, when the liquid assumed a rose color, and a solution of the sulphate emitted the characteristic odor of naphthalene.

According to Eber (*Ph. Centralb.,* 1892, 238) the well-known test for ammonia of exposing a glass rod dipped into hydrochloric acid to the fumes, is rendered more sensitive by using a mixture of hydrochloric acid 1 part, alcohol 3 parts, and ether 1 part, shaken together.

Composition.—Water is capable of absorbing 670 times its volume of ammonia gas at 10° C., and increases in bulk about two-thirds. But the official solution of ammonia is by no means a saturated one. Thus, the ammonia contained in the strongest U. S. preparation is about 28 per cent. The official table in Part III gives the percentage of ammonia gas in aqueous solutions of different densities at the temperatures of 25° C. and 15° C.

Ammonia Water is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, barium, or strontium, and only partially decomposes those of magnesium.

Uses.—When brought into contact with living tissue ammonium hydroxide acts as a stimulant, irritant, or caustic according to the strength of its solution. The official water of ammonia if applied for a short time to the skin produces burning pain and redness, but if contact be maintained is capable of destroying the whole dermal tissue. The irritant effects of ammonia water are due to the hydroxyl ion, not to the ammonium. When injected into the circulation the water of ammonia produces the characteristic effects of the ammonium salts but for reasons pointed out (see under *Ammonii Carbonas*) it cannot be absorbed from the stomach in sufficient quantity to exercise any direct influence upon the general system. It is, however, often of service in sudden *syncope,* especially of nervous origin, even when given by the mouth. Its effects under these circumstances are due to the reflex stimulation of the vasomotor center from the irritation of the gastric mucous membrane. Still more marked action of the same nature may be elicited by smelling the fumes which arise from the ammonia water. When injected hypodermically, however, it is a powerful direct stimulant to the heart and vasomotor system, although somewhat fleeting in its effects. It was at one time brought forward as an antidote for *snake-venom,* but the only value it has in this condition is due to its stimulant effect upon the circulation. It is widely employed to correct *hyperacidity of the stomach,* especially where a local stimulant as well as an antacid effect is required.

In serious *collapse,* as pointed out above, it is necessary to inject the ammonia hypodermically, or better, intravenously. Half a drachm to a drachm diluted with half an ounce to an ounce of water may be slowly thrown directly into a vein. In some cases the drug has been simply used hypodermically, but is almost certain to cause severe local symptoms. On account of its cheapness, ammonia water is much used as an ingredient in stimulating liniments, especially when combined with olive or other oil.

Toxicology.—The symptoms of poisoning by ammonia are solely those of local irritation: pain in the mouth, throat, and epigastrium; vomiting and collapse from the severity of the gastritis. In some cases the irritation of the throat is so severe as to produce an acute edema of the glottis which may mechanically obstruct respiration, and rapid death from asphyxia has occurred. In the treatment of the condition, diluted acetic acid in the form of vinegar may be used as an antidote; olive oil or other fatty substance is useful not only because it combines with the caustic alkali to form a comparatively non-irritant soap, but also by virtue of its local soothing action upon the inflamed mucosa. In case of edema of the larynx, tracheotomy is indicated; it should not be forgotten that this accident may be postponed for an hour or two after the ingestion of the poison and the physician should remain ready for immediate operation if necessary. The subsequent treatment is purely symptomatic.

Dose, ten to thirty minims (0.6–1.8 cc.), largely diluted.

Off. Prep.—Linimentum Ammoniæ, *N. F., Br.;* Linimentum Hydrargyri, *Br.;* Lotio Ammoniacalis Camphorata, *N. F.;* Spiritus Ammonii Aromaticus, *U. S.;* Linimentum Opii Compositum, *N. F.;* Linimentum Saponato-Camphoratum, *N. F.;* Spiritus Ammonii Anisatus, *N. F.*

AQUA AMMONIÆ FORTIOR. U. S. (Br.)

STRONGER AMMONIA WATER Aq. Ammon. Fort.

"Stronger Ammonia Water is an aqueous solution of ammonia (NH_3), containing not less than 27 per cent. and not more than 29 per cent. by weight of NH_3. This solution deteriorates rapidly and must be assayed frequently. *Caution—Great care should be used in handling the liquid because of its caustic and irritating properties.*" *U. S.* "Strong Solution of Ammonia is an aqueous solution containing 32.5 per cent. by weight of ammonia, NH_3. It may be obtained by heating a mixture of ammonium chloride and slaked lime, and passing the resulting ammonia into distilled water." *Br.*

Liquor Ammoniæ Fortis, *Br.;* Strong Solution of Ammonia; Eau d'Ammoniaque forte, *Fr.;* Stärker Salmiakgeist, *G.*

This preparation is too strong for internal exhibition, but forms a convenient ammonia solution for reduction, by dilution, to the strength of ordinary Ammonia Water, or for preparing strong rubefacient liniments.

Stronger Ammonia Water is prepared on a large scale, from one of the products of the coal gas manufacture, by the process of distilling *gas liquor;* the distillate, which is principally ammonium sulphide, is then converted into ammonium sulphate by sulphuric acid. The sulphate is gently distilled with milk of lime, the still being connected with a series of glass carboys, arranged like Woulff's bottles, and three-fourths filled with distilled water. In this way solution of ammonia may be obtained of maximum strength. It is also made by diluting the concentrated liquid ammonia.

Anhydrous liquefied ammonia is now an article of commerce, being used on a large scale in the manufacture of artificial ice and in refrigerating plants, where the cold produced by its rapid evaporation under a partial vacuum is utilized to furnish the necessary lowering of temperature. The apparatus used for its production is almost identical with that employed in the manufacture of liquid carbon dioxide, and consists of a combination of vacuum and condensing pumps. The gas is obtained from the strongest ammonia water by heating, with application of a partial vacuum, and must be well dried before the compression. To obtain a pure product, it has been found best to allow the liquefied ammonia to expand several times in a gasometer, in which case, the larger part of the impurities are left behind in liquid form. These consist of water, alcohol, acetone, traces of the lubricating oil from the compressing pumps, and a little ammonium carbonate. In ammonias made from the distillation of bones, pyridine is also found to occur as an impurity. Liquefied ammonia comes into commerce in steel cylinders which have been tested to stand 100 atmospheres internal pressure, and are provided with well fitting screw valves. Anhydrous ammonia is said to dissolve metallic sodium, and the solution is intensely blue.

Stronger ammonia water of the U. S. is somewhat weaker than the corresponding strong solution of ammonia of the Br.

Description and Physical Properties.—"A colorless, transparent liquid, having an excessively pungent, characteristic odor, and a very caustic and alkaline taste. *Stronger Ammonia Water must never be tasted nor smelled unless greatly diluted.* Specific gravity: about 0.897 at 25° C. Stronger Ammonia Water is strongly alkaline to litmus paper. Stronger Ammonia Water diluted with twice its volume of distilled water conforms to the tests for identity and purity under *Aqua Ammoniæ.*

"**Assay.**—Pour into a weighing bottle about 25 cc. of distilled water, tare the bottle and its contents, add about 2 cc. of Stronger Ammonia Water, and weigh accurately. Then titrate with normal sulphuric acid, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.01703 Gm. of NH_3.

"Preserve in a cool place in partly filled, strong, glass-stoppered bottles made of hard glass, free from lead." *U. S.*

"A colorless liquid, with a characteristic, very pungent odor. Strongly alkaline. Specific gravity 0.888. 1 gramme requires for neutralisation 19.1 millilitres of *N/1 solution of sulphuric acid.* When mixed with an equal volume of *water* and a slight excess of *sulphuric acid* no color or odor is developed (absence of tarry matters). Yields no characteristic *reactions* for aluminium, zinc, calcium, magnesium, potassium, sodium, carbonates, sulphates, or sulphides, and only the slightest *reactions* for chlorides. 0.5 millilitre of *solution of sodium sulphide* added to 50 millilitres of Strong Solution of Ammonia contained in a Nessler glass produces no change of color (absence of copper, iron, and lead). *Arsenic limit* 0.5 part per million. Leaves no appreciable residue on evaporation." *Br.*

Great care should be exercised in opening bottles containing stronger ammonia water. It is safer, if the ammonia water has been kept in a warm room, to cool it with ice before attempting to withdraw the stopper, as the liberated gas, when warm, frequently is forced out with extreme violence, and accidents which have resulted in injury to the sight of the operator are recorded.

Uses.—This solution is too strong for medicinal use in its unmixed state. Sufficiently diluted with spirit of camphor and rosemary, it was formerly much employed as a prompt and powerful rubefacient, vesicatory, or escharotic, in various *neuralgic, gouty, rheumatic, spasmodic,* and *inflammatory affections* in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired five parts of the stronger ammonia water may be mixed with eight parts of the diluent. This will answer even for blistering or cauterizing, unless a very prompt effect be necessary. In the latter case a lotion may be resorted to consisting of five measures of the ammonia to three of the diluent liquid. These mixtures are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode of applying is to fill the wooden cover of a pill or ointment box, an inch or two in diameter, with purified cotton, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in from one to eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer time.

When a solution of ammonia of 25° C. (sp. gr. 0.905) is mixed with fatty matter, the mixture forms the *vesicating ammoniacal ointment* of Gondret. The revised formula of this ointment is as follows: Take of lard 32 parts, oil of sweet almond 2 parts. Melt them together by a *gentle* heat, and pour the melted mixture into a bottle with a wide mouth. Then add 17 parts of solution of ammonia of 25° C., and mix with continued agitation until the whole is cold. The ointment must be preserved in a bottle with a ground stopper, and kept in a cool place. When well prepared, it vesicates in ten minutes.

There may be danger of excessive irritation and inflammation of the nostrils, mouth, and air passages, from the inadvertent inhalation of the gas escaping from a bottle of the stronger ammonia water, when freshly opened; and serious consequences have occurred from this cause, or from the accidental breaking of the bottle. The best antidote, under these circumstances, is the inhalation of the vapors of vinegar or acetic acid.

Dose, three to six minims (0.2–0.4 cc.), largely diluted.

Off. Prep.—Linimentum Camphoræ Ammoniatum, *Br.;* Liquor Ammoniæ, *Br.;* Spiritus Ammoniæ Aromaticus, *Br.;* Spiritus Ammoniæ Fetidus, *Br.*

AQUA ANETHI. Br.

DILL WATER

Eau d'Aneth, *Fr.*, Dillwasser, *G.*

"Dill Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand millilitres. In preparing this and other similar aqueous liquids by distillation, only good natural potable water must be employed, as directed for 'Distilled Water.'" *Br.*

"This Water may be prepared by triturating the oil of dill with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

This water, which is frequently prescribed in Great Britain, is occasionally used here; it closely resembles fennel or anise water, over which it has no advantages. It is used only as a vehicle.

AQUA ANISI. U. S., Br.

ANISE WATER Aq. Anisi

"A saturated solution of oil of anise in distilled water, prepared by one of the processes for aromatic waters." *U. S.*

Eau d'Anis, *Fr.;* Aniswasser, *G.;* Acqua distillata di anice, *It.;* Agua destilada de anis, *Sp.*

"Anise Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand millilitres." *Br.*

"This water may be prepared by triturating the oil of anise with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Anise water is rarely made by distillation, although the product thus secured has a more delicate flavor than the U. S. preparation. It is used solely as a vehicle.

AQUA AURANTII FLORUM. U. S. (Br.)

ORANGE FLOWER WATER Aq. Aurant. Flor.

[Aqua Aurantii Florum Fortior, U. S. P. IX.]

"A saturated solution of the odoriferous principles of the flowers of *Citrus Aurantium* (var. *amara*) Linné (Fam. *Rutaceæ*), prepared by distilling the fresh flowers with water and separating the clear, saturated portion of the distillate. Its odor is best preserved by allowing a limited access of fresh air to the container." *U. S.*

"Orange-flower Water is the orange-flower water of commerce, prepared by distillation from the flowers of the Bitter Orange tree, Citrus Aurantium, var. Bigaradia, *Hook., f.*, diluted, immediately before use, with twice its volume of distilled Water." *Br.*

Aqua Aurantii Floris, *Br.;* Aqua Florum Naphæ; Aqua Aurantii Florum Fortior *U. S. IX;* Stronger Orange-flower Water; Triple Orange-flower Water; Hydrolatum Floris Citri Vulgaris; Eau distillée (Hydrolat) de Fleurs d'Oranger, *Fr. Cod.;* Eau de Naphe, *Fr.;* Orangenblüthenwasser, *G.;* Acqua distillata di arancio, *It.;* Agua destilada de azahar, *Sp.*

The U. S. P. IX recognized two grades of orange flower water, one of them known as *Aqua Aurantii Florum Fortior,* corresponding in strength to the distillate commercially known as "orange flower water," and the other a dilution of this with distilled water. In the U. S. P. X that latter has been omitted and only the stronger recognized. The British Pharmacopœia recognizes only the more dilute water which is made by diluting the "orange flower water of commerce" with two parts of distilled water. The British orange flower water has therefore about one-third the strength of the American.

The advantage of the stronger orange flower water is that it retains its fragrance longer than the dilute solution. Its odor, however, is too strong for most pharmaceutical processes and it should be diluted with one to two parts of distilled water when used as a vehicle.

Orange flower water is manufactured chiefly in Italy and France although small quantities have been distilled in this country. The flowers of the bitter orange are preferred as yielding the most fragrant product.

L. Malenfant observed that fresh orange flowers, mixed with cold water, yield, on distillation over the naked fire, a milky water, possessing a somewhat empyreumatic odor and a strong, somewhat acrid taste. Kept for twelve or eighteen months in glass vessels covered with parchment, it loses its empyreuma, and after filtering has an agreeable odor and taste. If the flowers be mixed with boiling water and immediately distilled, the water is limpid, and gradually separates some thick oil of a brownish color; the water has the odor and taste of the flowers, but complicated with an odor of the still, which it loses after long keeping; it seems to alter less rapidly than that obtained by the former process. Distilled by steam, limpid water of a pure odor and taste is at once obtained, free from empyreuma; it may be at once used, and keeps better in the light than when obtained by the two former processes. (*A. J. P.,* June, 1874.) Hesse and Zeitschel (*J. Pr. Chem.,* 1901, 525) found by exhausting with ether the orange flower water obtained in the distillation of the orange blossoms that the quantity of oil dissolved in the water represented about one-third of the total amount of oil from the blossoms. A distilled water of the leaves is also prepared, and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (*J. P. C.,* 4e sér., iii, 249.)

Orange flower water is stored in large glass vessels of carboys in cool cellars by the manufacturers in Grasse, France, care being taken not to stopper them tightly, but simply cover the orifice with a piece of paper or coarse cloth.

Nitric, sulphuric, or hydrochloric acid produces a red coloration with orange flower water, particularly if the water be shaken with ether to take up the oil, and the acid added to the ethereal solution.

Description and Physical Properties.—"Nearly colorless and clear or only faintly opalescent, possessing a strong, pleasant odor and taste of orange blossoms. It must be free from empyreuma, mustiness, or fungoid growths.

"Orange Flower Water is neutral or only slightly acid to litmus paper. Evaporate 100 cc. of the Water on a water bath, and dry the residue to constant weight at 100° C.: not more than 0.001 Gm. of residue remains. Orange Flower Water shows no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (*metallic impurities*)." *U. S.*

"Colorless or with a slight yellowish tint; odor vary fragrant. Yields no *reactions* for lead or copper. The orange-flower water of commerce is a saturated solution of the volatile oil of the fresh flowers." *Br.*

From being kept in tinned copper cans, it sometimes contains metallic impurity, which is said to be chiefly lead carbonate, derived from the lead used as a solder in making the cans. The means of detecting metallic impurity is also mentioned under the general observations on distilled water. Much color, offensive odor, or mouldiness indicates impurity derived from the flowers in distillation.

Uses.—Orange flower water is used solely for its pleasant odor to perfume external lotions or to flavor internal medicines.

Off. Prep.—Syrupus Aurantii Florum, *U. S.;* Syrupus Aurantii Floris, *Br.;* Elixir Amygdalæ Compositum, *N. F.;* Elixir Aurantii Amari, *N. F.;* Elixir Glycyrrhizæ Aquosum, *N. F.*

AQUA CAMPHORÆ. U. S. (Br.)

CAMPHOR WATER Aq. Camph.

"A saturated solution of camphor in distilled water, prepared by one of the processes for aromatic waters, using 2 Gm. of powdered camphor in each 1000 cc." *U. S.*

Aqua Camphorata; Eau camphrée *Fr.;* Kampher-wasser, *G.;* Agua alcanforada, *Sp.*

"Camphor, 1 *gramme;* Alcohol (90 per cent.), 2 *millilitres;* Distilled Water, 1000 *millilitres.* Dissolve the Camphor in the Alcohol; add the solution in successive portions to the Distilled Water, shaking after each addition; finally shake occasionally until all the Camphor is dissolved." *Br.*

In this process the sole object is to effect a solution; water is capable of dissolving but a very small proportion of camphor, but the quantity varies with the method employed. The present British process is more efficient than the old formula, a definite quantity of camphor being dissolved in a small quantity of alcohol and this solution gradually added to the proper quantity of water; it is questionable, however, whether it would not be advantageous to use an insoluble powder to aid in the solution and thus obtain quickly a clear liquid, as the water made by the British process is sometimes cloudy. In the former British process no trouble was taken even to comminute the camphor, or to shake it with the water, which was thus allowed to take up what it might be disposed to do by contact with the camphor contained in a bag. The solution thus affected was extremely feeble, containing probably less than one part in a thousand; this proportion, according to Berzelius, is taken up by water when triturated with camphor. It was, besides, of uncertain strength, varying with the size of the fragments of camphor. Wm. B. Addington proposed to add to the camphor just enough alcohol to dissolve it, and triturate the liquor with magnesia, during which process he affirmed that the alcohol evaporated (*A. J. P.*, xlv, 209); and F. T. Hartzell substituted ether for alcohol, a few drops of which enabled him to bring the camphor to an impalpable powder. John K. Thum states that in the U. S. process part of the camphor remains with the talc on the filter and proposes to make camphor water by using eight grammes of camphor in small pieces and adding it to 1000 cc. of distilled water, shaking the bottle until the solution is saturated and filtering through sterilized gauze. (*Proc. Pennsylvania P. A.*, 1913, 364.) Camphor is separated from its aqueous solution by a solution of pure potassium hydroxide, and, according to Paris, by magnesium sulphate and several other salts. J. Murray proposes a solution of camphor and magnesium bicarbonate, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is too feeble a preparation for use when a decided effect is desired; it is, however, an excellent vehicle for the administration of more active substances.

Dose, half to one fluidounce (15–30 cc.), repeated every one or two hours.

Off. Prep.—Mistura Camphoræ Acida, *N. F.;* Mistura Camphoræ Aromatica, *N. F.*

AQUA CARUI. Br.

CARAWAY WATER

Aqua Carvi; Eau Distillée de Carvi, *Fr.;* Kümmelwasser, *G.*

"This Water may be prepared by triturating the oil of caraway with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

"Caraway Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand *millilitres.*" *Br.*

Distilled Caraway Water has the flavor of the fruit or seeds, but is seldom used in the United States. The water made from the volatile oil (16 minims in a pint), in the same manner as is cinnamon water, is largely employed. It is used only as a vehicle.

AQUA CHLOROFORMI. U. S., Br.

CHLOROFORM WATER Aq. Chlorof.

Eau Chloroformée, *Fr.;* Chloroformwasser *G.;* Agua Cloroformada, *Sp.*

"Chloroform, Distilled Water, each, a sufficient quantity. To a convenient quantity of distilled water contained in a dark amber-colored bottle, add enough chloroform to maintain a slight excess after the contents have been repeatedly and thoroughly shaken. When Chloroform Water is required for use, pour off the needed quantity, refill the bottle with distilled water, and saturate it by thorough agitation, taking care that there is always an excess of chloroform present.

"Preserve in well-stoppered, amber-colored bottles." *U. S.*

"Chloroform, 2.5 *millilitres;* Distilled Water sufficient to produce 1000.0 *millilitres.* Dissolve." *Br.*

The water should be fully saturated, in which case it should contain one-half per cent. of chloroform. Chloroform water has been proved to be an excellent vehicle for administering active remedies, and, owing to its antiseptic properties, mixtures having it for a basis resist decomposition longer than those made with ordinary water.

Dose, one-half to two fluidounces (15–60 cc.).

AQUA CINNAMOMI. U. S., Br.

CINNAMON WATER Aq. Cinnam.

"A saturated solution of oil of cinnamon in distilled water, prepared by one of the processes for aromatic waters." *U. S.*

Hydrolatum Cinnamomi, Eau distillée de Cannelle, *Fr. Cod.;* Aqua Cinnamomi, *P. G.;* Zimmtwasser, *G.;* Acqua distillata di canella, *It.;* Agua destilada de canela, *Sp.*

"Cinnamon Bark, bruised, 100 *grammes;* Water, 2000 *millilitres.* Distil *one thousand millilitres.*" *Br.* "This Water may be prepared by triturating the oil of cinnamon with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

On standing, cinnamon water, made from oil of Ceylon cinnamon, is apt to precipitate, owing to the gradual oxidation and formation of cinnamic acid, which is comparatively insoluble in water: this can be prevented, according to E. Backhaus, by passing a stream of carbon dioxide through the fresh water for a few minutes. We have never seen the precipitation successfully prevented, notwithstanding the application of numerous so-called preventives; these usually delay the precipitation, but in a few weeks' time the cloudiness due to the formation of minute crystals of cinnamic acid invariably appears. When oil of cassia cinnamon is used as directed in the U. S. process precipitation rarely occurs. E. Holmes recommends glycerin as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect the solution of a drop of the oil in a fluidounce of water.

Cinnamon water is much used as a vehicle for other less agreeable medicines, but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water.

Off. Prep.—Cinnamon water is used to flavor several official preparations besides the following vehicles: Mistura Spiritus Vini Gallici, *Br.;* Syrupus Aromaticus, *Br.;* Syrupus Cinnamomi, *N. F.*

AQUA DESTILLATA. U. S., Br.

DISTILLED WATER Aq. Dest.

"Water (H_2O) purified by distillation." *U. S.* "Distilled Water is prepared by distillation from good natural potable water." *Br.*

Eau distillée, *Fr. Cod.;* Aqua distillata, *P. G.;* Destillirtes Wasser, *G.;* Acqua distillata, *It.;* Agua destilada, *Sp.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above process for its distillation. It is best to reject the first portion which comes over, as this may contain carbon dioxide and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of block tin or glass. The large stills for making distilled water commercially are not run upon the principle of the rejection of the first and the last portions, as they are continuous in their operation. They are all provided with a vent at the highest portion of the condensing system where a small amount of steam escapes, carrying with it the gases which ordinarily would contaminate the condensed distillate. Commercial distilled waters are frequently passed through charcoal filters to aerate the water and remove the flat insipidity of taste. Brande states that distilled water often derives from the still a foreign flavor, which it is difficult to avoid. He therefore recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of steaming it out, before it is used, the worm-tub having been previously emptied. J. N. Hurty prefers well water as the source of distilled water, and that it be boiled before collecting the distillate, to get rid of ammonia, and, to prevent access and growth of spores, that the water be heated to boiling before introducing it into the container, and that it be drawn off by a siphon tube reaching to the bottom of the vessel, the mouth of which is loosely stoppered with cotton. (*West. Drug.,* 1887, p. 4.) Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity, as water distilled from metallic alembics with the head and worm of this metal has a peculiar odor which it retains for some time. Ordinary distilled water often contains ammonia, as may be proved by adding a few drops of Nessler's reagent. (See Part III.) In order to free distilled water from volatile nitrogenous bodies, it is necessary to redistil it after it has been placed in contact with potassium permanganate and potassium hydroxide. After about one-twentieth of the water has come over, the distillate is usually free from ammonia, and leaves no residue on evaporation. If traces of ammonia remain, acid potassium sulphate is added, and it is redistilled. (Stas.) Distilled water when kept long in glass vessels dissolves a minute quantity of the glass and the official test permitting 0.075 Gm. of residue in 1000 cc. after evaporation to dryness, was inserted to avoid unnecessary severity in the test for a solvent used for pharmaceutical purposes. Williams and Swett (*J. A. M. A.,* 1922, lxxviii, 1024) have shown that distilled water tends to become acid in reaction on standing.

Properties.—Distilled water, as usually obtained, has an insipid taste, which is very different from that of ordinary potable water. Inasmuch as distilled water has a solvent action upon glass the purest distilled water is distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua.*

Description and Physical Properties.—"A colorless, limpid liquid, without odor or taste, and neutral to phenolphthalein T.S. and to methyl orange T.S.

"Evaporate 100 cc. of Distilled Water to dryness on a water bath, and subsequently dry the residue in an oven to constant weight at 100° C.: not more than 0.001 Gm. of residue remains. Separate portions of 100 cc. each of

Distilled Water are not affected by the addition of barium chloride T.S. (*sulphate*); silver nitrate T.S. (*chloride*); ammonium oxalate T.S. (*calcium*); hydrogen sulphide T.S. (*metals*). Distilled Water shows no deep yellow, orange or brown coloration when 1 cc. of alkaline mercuric potassium iodide T.S. is added to a 100 cc. portion (*ammonia*). Add 50 cc. of calcium hydroxide T.S. to 25 cc. of Distilled Water: the mixture remains clear and transparent (*carbon dioxide*). Heat 100 cc. of Distilled Water to boiling, acidulate with 10 cc. of diluted sulphuric acid, and subsequently add 0.1 cc. of tenth-normal potassium permanganate: the color of the liquid is not completely destroyed by boiling for ten minutes (*oxidizable substances*)." *U. S.*

The British Pharmacopœia requires distilled water to be "colorless, odorless, and tasteless. Yields no *reactions* for sulphates, chlorides, or nitrates. 100 millilitres evaporated to dryness on a water-bath leave not more than 0.005 gramme of solid residue. 50 millilitres with one drop of *solution of sodium sulphide* remain colorless when viewed in a Nessler glass standing on a white tile (absence of lead, copper, and iron). 250 millilitres with a mixture of 3 millilitres of *sulphuric acid* and 0.1 millilitre of *N/10 solution of potassium permanganate,* after standing for three hours at about 15.5° C., are colored blue on the addition of a crystal of *potassium iodide* and 1 millilitre of *mucilage of starch* (absence of more than traces of organic matter). 50 millilitres mixed with 2 millilitres of *alkaline solution of potassio-mecuric iodide* when viewed in a Nessler glass standing on a white tile do not, after five minutes, yield a more intense color than that yielded by 50 millilitres of ammonia-free water with 0.5 millilitre of *dilute solution of ammonium chloride* (*Nessler's*) when tested under similar conditions (limit of ammonia)." *Br.*

It is needlessly employed in some formulas, but is essential in others. As a rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, silver nitrate, barium and calcium chlorides, lead acetate and subacetate, potassium permanganate, iron and zinc sulphates, quinine sulphate, morphine sulphate, hydrochloride, and acetate, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the official diluted acids, for absorbing gaseous ammonia, and for forming nearly all the official aqueous solutions.

AQUA DESTILLATA STERILISATA. U. S.

STERILIZED DISTILLED WATER Aq. Dest. Steril.

"Water, freshly distilled, a sufficient quantity. Place freshly distilled water, neutral to litmus paper, in sterilized containers of insoluble glass, having a capacity of not over 1000 cc. each. Stopper the containers with plugs of purified absorbent cotton, wrapped in gauze. Fasten stout, non-absorbent paper or tinfoil over the top of the plug and the lip of the flask, and sterilize in an autoclave, under steam pressure giving a temperature of 115° C., for thirty minutes. If an autoclave is not available, close the mouth of the flask containing the freshly distilled water with a plug of purified absorbent cotton wrapped in gauze, boil the contents actively for one hour and allow the water to cool without removing the cotton plug. Until ready for use, protect the mouth of the flask and the plug from infection through dust by wrapping the top of the flask tightly with paper.

"Sterilized Distilled Water should be used within twenty-four hours after its distillation if it is to be employed for intravenous injection. For other uses, it is preferable that the Water be resterilized after each opening and that it be used within a mouth after its preparation." *U. S.*

Distilled water is ordinarily not sterile, due to the contamination of the vessels in which it is collected or by air-borne organisms. For the preparation of hypodermic injections, therefore, and for some other purposes it is necessary to re-sterilize the distilled water, hence the admission of this sterilized water into the Pharmacopœia.

It is of the utmost importance that the water to be sterilized shall be freshly distilled, since distilled water which has stood even for a short time will contain many bacteria which, if present, would be killed by the sterilization process, but subsequently form a bacterin (a suspension of dead bacteria), and this if used for dissolving salts for hypodermic injection is apt to cause febrile and other systemic disturbances. If the U. S. method is followed the flask must be of so-called insoluble glass, such as Jena glass, or the solution will contain silicates which are likely to separate as needle-like spicula. Sterilized distilled water may to advantage be prepared in an autoclave. The container should be sterilized before filling and then both water and container re-sterilized.

AQUA FŒNICULI. U. S., Br.

FENNEL WATER Aq. Fœnic.

"A saturated solution of oil of fennel in distilled water, prepared by one of the processes for aromatic water." *U. S.*

Eau de Fenouil, *Fr.;* Aqua Fœniculi, *P. G.;* Fenchelwasser, *G.;* Acqua distillata di finocchio, *It.;* Agua de hinojo, *Sp.*

"Fennel Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand *millilitres.*" *Br.*

"This Water may be prepared by triturating the oil of fennel fruit with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Uses.—Fennel water is a pleasant vehicle for other medicines, and useful when a mild aromatic is indicated. The distillation process of the British Pharmacopœia, although more troublesome, furnishes a more delicate and agreeable water than does that of the U. S. Pharmacopœia.

AQUA LAUROCERASI. Br.

CHERRY-LAUREL WATER

Hydrolatum Laurocerasi, Eau distillée de Laurier-cerise, *Fr. Cod.;* Kirschlorbeerwasser, *G.;* Agua destilada de laurel-cerezo, *Sp.*

"Cherry-Laurel Leaves, crushed, 800 *grammes;* Water, 2500 *millilitres.* Distil one thousand *millilitres;* shake the product; filter, if necessary; adjust the strength of the finished product either by adding hydrocyanic acid or Distilled Water, so that, when tested as described under 'Acidum Hydrocyanicum Dilutum,' it contains 0.1 per cent. by weight of hydrocyanic acid, HCN." *Br.*

The International Protocol (1906) fixed the strength of Cherry-Laurel Water at 0.1 per cent. of hydrocyanic acid which corresponds with the strength of the Br. Pharm, 1898 and 1914.

It is greatly to be regretted that this uncertain, dangerous, and troublesome preparation should retain a place in European pharmacopœias, inasmuch as it could easily be replaced by a flavored water containing a definite amount of a soluble cyanide. See *S. W. P.,* 1909, No. 10, 147, and 1909, No. 36, 542.

As the cherry-laurel is little cultivated in the United States, the water is not official; but from several experiments by William Procter there is little or no room to doubt that a preparation identical in its effects might be made from the leaves of our common wild cherry, *Prunus serotina.* The imported cherry-laurel water, as found in commerce, is generally impaired by age, and not to be relied on.

Cherry-laurel leaves contain 65 per cent. of water, sufficient to provoke the reaction which results in the formation of a volatile oil and hydrocyanic acid. Water is very prone to hasten the conversion of the benzaldehyde, contained in the volatile oil, into benzoic acid by oxidation, and it has been found by C. Umney (*P. J.,* x, 467) and by Moore (*Ibid.,* 604) that the water distilled without previous maceration is somewhat stronger in hydrocyanic acid and decidedly stronger in oil (Umney) than the official product. The strength of cherry-laurel water was formerly very variable, but the British Pharmacopœia requires 0.1 per cent. of hydrocyanic acid. The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by Deschamps that if a drop of sulphuric acid be added to a pint of the preparation it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*J. P. C.,* xvi, 346.) For Denigés' method of assaying the water, see *Proc. A. Ph. A.,* 1894, 556.

Uses.—Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a diluted solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the preparation of the acid now in use.

Dose, twenty minims to a fluidrachm (1.3–3.75 cc.).

AQUA MENTHÆ PIPERITÆ. U. S., Br.

PEPPERMINT WATER Aq. Menth. Pip.

"A saturated solution of oil of peppermint in distilled water, prepared by one of the processes for aromatic waters." *U. S.*

Hydrolatum Menthæ Piperitæ, Eau distillée de Menthe poivrée, *Fr. Cod.;* Aqua Menthæ Piperitæ, *P. G.;* Pfefferminzwasser, *G.;* Acqua distillata di menta piperita, *It.;* Agua destilada de menta piperita, *Sp.*

"Oil of Peppermint, 1 *millilitre;* Water, 1500 *millilitres.* Distil one thousand *millilitres.*" *Br.*

"This Water may be prepared by triturating the oil of peppermint with twice its weight of calcium phosphate and five hundred times its volume of distilled water, and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Uses.—Peppermint water is one of the most popular of the aqueous vehicles. It is especially useful as an ingredient in mouth washes because the menthol content produces a pleasant and cool sensation on mucous membranes.

Off. Prep.—Liquor Sodæ et Menthæ (Alternative with Spearmint), *N. F.*

AQUA MENTHÆ VIRIDIS. U. S., Br.

SPEARMINT WATER Aq. Menth. Vir.

"A saturated solution of oil of spearmint in distilled water, prepared by one of the processes for aromatic waters." *U. S.*

Eau de Menthe verte, *Fr.;* Römisch-Minzwasser, *G.;* Agua de yerba buena, *Sp.*

"Oil of Spearmint, 1 *millilitre;* Water, 1500 *millilitres.* Distil one thousand *millilitres.*" *Br.*

"This Water may be prepared by triturating oil of spearmint with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

There would seem to be no good reason for distilling the mint waters from their respective volatile oils, as directed in the British processes. If the fresh plants were available, a good source for a distilled water could be provided; but if a volatile oil must be used with its uncertainty of freshness always present, the quicker process of the U. S. P. is greatly preferable.

Uses.—Spearmint water is used solely as a vehicle. Its flavor to most persons is inferior to that of peppermint, and it lacks the characteristic cooling effect of the menthol which is found in peppermint.

Off. Prep.—Liquor Sodæ et Menthæ, *N. F.*

AQUA ROSÆ. U. S. (Br.)

ROSE WATER Aq. Ros.

Hydrolatum Rosæ, Eau distillée de Rose, *Fr. Cod.;* Aqua Rosæ, *P. G.;* Rosenwasser, *G.;* Acqua distillata di Rose, *It.;* Agua destilada de rosas, *Sp.*

"Stronger Rose Water, Distilled Water, each, 1 volume. Mix them immediately before use.

"Rose Water complies with the description and tests under *Aqua Rosæ Fortior.*" *U. S.*

The British Pharmacopœia of 1898 abandoned the former process of distilling the petals and followed the method adopted by the U. S. Pharmacopœia of diluting the so-called triple rose water of commerce with distilled water. This, however, does not make rose water identical in strength in these authorities, the U. S. preparation being the stronger.

Although domestic rose water of fair quality may be made by distilling fresh rose petals, it does not possess the strength or delicacy of the by-product obtained from abroad, as officially described under *Aqua Rosæ Fortior;* hence the above process of diluting this stronger rose water. The process of distilling the fresh petals of the hundred-leaved rose is sometimes practised. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odor, and afford a water equally fragrant with that prepared from the fresh flowers. Indeed, Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and keeps its odor better than that prepared from the fresh flowers. (*P. J.*, xvi, 15.) It is not uncommon to employ the whole flower, including the calyx; but the product is less fragrant than when the petals only are used, as officially directed. A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the center of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, coagulating the mucilaginous matter of the petals, and preventing it from passing over in the distillation. (*J. P. C.*, 1863, p. 497.) Rose water is sometimes made by distilling together water and the oil of rose. This is best performed by dropping 10 drops of oil of rose on a sponge and adjusting it in the upper part of a still in the body of which a gallon of water is placed; the steam from the boiling water will carry over portions of the oil, and the distillate will thus be impregnated. Alpers (*Am. Drug.*, 1896, 384) prepares rose water by dropping 10 drops of oil of rose into a liter of hot distilled water, agitating and filtering. Rauschenberger improves the flavor by adding a trace of oil of cloves; 2.5 Gm. of oil of rose, 0.25 Gm. of oil of cloves are added to sufficient alcohol to make 100 cc.; then 10 cc. of this solution is added to 1000 cc. of boiling water and the liquid cooled and filtered.

Rose water, when properly prepared, has the perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters, it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. It may be kept in a bottle stoppered with a plug of absorbent cotton. This distilled water is chiefly employed, on account of its agreeable odor, in collyria and other lotions. It is wholly destitute of irritating properties, unless it contain alcohol, although it is not suitable for dissolving silver nitrate on account of the reducing power of the small amount of volatile oil present.

Off. Prep.—Mistura Ferri Composita, *Br.;* Linimentum Terebinthinæ Aceticum, *N. F.;* Mistura Ferri Composita, *N. F.;* Unguentum Aqua Rosæ, *Br.*

AQUA ROSÆ FORTIOR. U. S.

STRONGER ROSE WATER Aq. Ros. Fort.

"A saturated solution of the odoriferous principles of the flowers of *Rosa centifolia* Linné (Fam. *Rosaceæ*), prepared by distilling the fresh flowers with water and separating the clear saturated portion of the distillate. Its odor is best preserved by allowing a limited access of fresh air to the container." *U. S.*

Rose Water of Commerce, *Br.*, [Triple Rose Water] Aqua Rosæ, *U. S.* 1880; Stärkeres Rosenwasser, *G.*

This has been introduced for the purpose of making rose water. (See the preceding article.)

Description and Physical Properties.—"Rose Water is nearly colorless and clear, possessing a strong, pleasant odor and taste of fresh rose blossoms. It must be free from empyreuma, mustiness, or fungoid growths. It is neutral or only slightly acid to litmus paper. Evaporate 100 cc. of the Water on a water bath, and dry the residue to constant weight in an oven at 100° C.: not more than 0.001 Gm. of residue remains. Stronger Rose Water shows no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (*metallic impurities*)." *U. S.*

Off. Prep.—Aqua Rosæ, *U. S., Br.;* Unguentum Aquæ Rosæ, *U. S., Br.;* Confectio Rosæ, *N. F.*

AQUÆ AROMATICÆ

AROMATIC WATERS

"Aromatic Waters are saturated solutions (unless otherwise specified) of volatile oils or other aromatic or volatile substances in distilled water. They are clear and free from solid impurities. They possess an odor similar to the plant or volatile substance from which they are made, and are free from empyreumatic or foreign odors. Aromatic Waters should be protected from strong light and preferably stored in containers which are stoppered with purified cotton to allow access of some air but to exclude dust.

"Aromatic Waters are prepared by one of the following general processes:" *U. S.*

Medicated Waters; Aquæ stillatitiæ; Aquæ Olei Volatili; Distilled Waters; Hydrolati; Eaux Medicinales, Eaux distillées, Hydrolats, *Fr.;* Aquæ Destillatæ, *P. G.;* Destillirte Wässer, *G.;* Acque distillate, *It.;* Aguas Destiladas, *Sp.*

"(*a*) *Distillation.*—Place the odoriferous portion of the plant or drug from which the Aromatic Water is to be prepared in a suitable still with sufficient water, and distil most of the water, carefully avoiding the development of empyreumatic odors through the burning of the substances. Separate any excess of oil, and preserve or use the clear aqueous portion, which should be saturated with the flavoring or aromatic principles of the plant.

"(*b*) *Solution.*—The Volatile Oil, or Other Specified Volatile Substance, 2 cc. or 2 Gm.; Distilled Water, a sufficient quantity, to make 1000 cc. Shake the volatile substance with 1000 cc. of distilled water in a capacious bottle, and repeat the shaking several times during a period of about fifteen minutes. Set the mixture aside for twelve hours or over night, filter through paper, and pass enough distilled water through the filter to obtain 1000 cc.

"If preferred, the Aromatic Water may be prepared by the above formula but with the addition of about 15 Gm. of purified talc, or a sufficient quantity of purified siliceous earth, or pulped filter paper, with which the volatile substance is thoroughly incorporated. Agitate the mixture well, and filter, returning the first portions of the filtrate until it comes through clear." *U. S.*

The Distilled Waters hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation has been bestowed there upon the various conditions calculated to furnish the best products by the most convenient method. The British Pharmacopœia (1914) directs the distillation process for the waters, but provides for certain medicated waters the alternative process as follows:

"**Aquæ Olei Anethi, Anisi, Carui, Cinnamomi, Fœniculi, Menthæ Piperitæ, Menthæ Viridis.**—Each of these Waters may be prepared by triturating the corresponding Oil with twice its weight of Calcium Phosphate and five hundred times its volume of Distilled Water and filtering the mixture. In tropical and subtropical parts of the Empire these Aquæ Olei may be used in place of the corresponding Aquæ of the Text of the Pharmacopœia." *Br.*

Many vegetable substances impart their peculiar flavor to water distilled from them, and more or less of their medicinal properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapor and are condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the Distilled Waters, dried plants are sometimes used, because fresh plants are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odor by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavor. Some pharmacists prefer to employ the salted flowers in certain instances, believing that the waters distilled from them keep better than when prepared from the fresh flowers. C. R. Tichborne proposed the method of simply immersing the fresh flowers in glycerin, which preserves them with all their aromatic properties wholly unimpaired.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previous to the operation. The quantity of materials should not bear too large a proportion to the capacity of the still, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state until the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the solid matter, lest a portion of the latter, coming in contact with the sides of the vessel, be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the still above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil bath, regulated by a thermometer, or of a bath of solution of calcium chloride, by which any temperature may be obtained between 100° C. and 132.2° C., according to the strength of the solution; or, when the process is conducted a large scale, by means of steam introduced under pressure into a space around the still termed a "jacketed body." To prevent the disagreeable effects of charring and the excessive empyreumatic odor frequently noticed in Distilled Waters, caused by the solid contents of the still coming into direct contact with the heated bottom, Remington devised an expedient which prevents the herb from touching the bottom and yet permits the water and steam to have free access to all parts of it. (See Pharmaceutical Still, under *Extracta.*) A hemispherical No. 12 copper sieve with a handle and loosely fitting lid is filled with the herb and placed in the water in the still. If the bottom of the still be flat or nearly so, the rounded bottom of the cage will have only a very slight point of contact, and thus charring will be prevented. A convenient mode of applying heat by steam is by means of a coil of metal tubing placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a steam-cock, by which the pressure may be increased or the condensed water drawn off at will.

The best mode of applying heat is generally conceded today to be the direct application of steam, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odor of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better.

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odor. They may be freed from this by exposure for a short time to the air before being enclosed in well-stoppered bottles, in which they should be preserved. When long kept, a viscid ropy matter is apt to form in them from the growth of micro-organisms and they lose their characteristic flavor and odor. To prevent this decomposition, a little alcohol is sometimes added to the water employed in its distillation. But this addition is inadequate, and is in fact injurious, as the alcohol by long exposure to the air undergoes the acetous fermentation. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia in several instances. It is said to afford a more permanent product than the preceding, but does not always preserve the flavor of the plant.

The U. S. Pharmacopœia X recognizes for the making of Aromatic Waters only the process of dissolving the separated volatile oil. In former editions the oil was directed to be triturated with some insoluble powder, which aids in the solution of the oil by causing its division into very small particles; the powder impregnated with the oil was then shaken with water and filtered. Magnesium carbonate was at one time used for the dispersing substance, but although it produces a water that has a fine flavor and appearance, the alkalinity imparted makes it unsuitable for many purposes. Among the various other substances that have been suggested for this purpose may be mentioned calcium phosphate (*U. S.* 1980), talcum (*N. F.*, 1888), kieselguhr (LaWall, *Proc. N. J. Ph. A.*, 1908) and absorbent cotton (*U. S.* 1880). Thum (*Proc. Pa. Ph. A.*, 1916, p. 225) showed that for the use of these an intervening filtering agent was unnecessary and the U. S. P. X recommends simple agitation with cold water, a period of maceration and subsequent filtration.

As alternative processes, purified talc, purified siliceous earth or pulped filter paper are permitted as distributing media. A very good way to make medicated waters when a volatile oil is directed, is that proposed by Percival, which is to heat the water required, pour it into a bottle and add the oil, cork tightly, shake occasionally until cool, then pour off and filter; this secures a medicated water free from foreign substances, and a saturated solution, most oils being more soluble in hot than in cold water. The Dublin College prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to objection in this account. In the preparation of the aromatic waters by these processes, it is very important that distilled water should be used, for tap water frequently contains constituents which have a deteriorating effect upon the aroma of the water.

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With potassium ferrocyanide, iron will give a blue color, zinc and lead white precipitates, and copper a rose color followed by a chestnut brown precipitate. Sodium sulphide causes with salts of iron, copper, or lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc a white precipitate.

ARALIA. N. F.

ARALIA [American Spikenard, Spignet]

"Aralia consists of the dried rhizome and roots of *Aralia racemosa* Linné (Fam. *Araliaceæ*). Aralia contains not more than 5 per cent. of its stem bases or other organic matter." *N. F.*

Indian Root, Pettymorrel; Nard-Americain, *Fr.;* Amerikanische Nard, *G.*

American Spikenard is a perennial herb with several widely branched, unarmed, aerial stems which arise to the height of 1 to 1.8 meters and bear ternately to quinately compound leaves, each with broadly ovate leaflets having acuminate apices, cordate bases and doubly serrate margins. The flowers are small greenish-yellow and borne on panicles of umbels. The fruits are sub-globular, dark purplish to reddish-brown berries. It is indigenous to Eastern North America west to Minnesota and Missouri. The rhizomes and roots are collected in summer and autumn, cut into segments, the thicker rhizomes cut lengthwise and all carefully dried. Most of the commercial drug comes from Indiana, Missouri, North Carolina, Virginia, Washington and Illinois.

Description and Physical Properties.—"*Unground Aralia.*—Rhizome, oblique, about 12 cm. long and 5 cm. thick, somewhat flattened, tortuous, externally pale brown, and often scaly, somewhat annulately roughened, frequently cut longitudinally, whitish internally; nodes approximate, each with a prominent stem scar about 3 cm. in width; fracture fibrous; roots numerous, of varying length, 5 to 25 mm. thick, furrowed, sometimes with transverse ridges and corky patches, usually cut longitudinally, light-brown or purplish-brown externally, whitish and spongy internally, fracture of the cortex short, of the wood short and fibrous. Odor aromatic; taste mucilaginous, pungent and slightly acrid.

"*Structure.*—Root with a thick bark composed of several zones of secretion reservoirs containing oil, and surrounded by parenchyma, a well developed cork with one or more hypodermal layers of lignified cells; wood more or less distinctly radiate.

"*Powdered Aralia.*—Starch grains spherical or angular, single or 2- or more compound, 0.005 to 0.025 mm. in diameter; rosettes of calcium oxalate, 0.030 to 0.070 mm. in diameter, tracheæ with scalariform or reticulate thickenings and simple or bordered pores; characteristic lignified cells from the hypodermis 0.040 to 0.100 mm. in length and about one-half as broad, their walls showing simple pores (distinction from *Aralia nudicaulis*)." *N. F.*

Closely allied to the official species, both botanically and therapeutically, are the *A. nudicaulis* L. (*American, False* or *Wild Sarsaparilla* or *Shot-bush*) and the *A. spinosa* L. (*Angelica Tree, Hercules Club* or *Prickly Elder*). The latter has sometimes been referred to, improperly, as "prickly ash" and has occurred as an adulterant of the true prickly ash, *Xanthoxylum Americanum.*

As far as we know *A. racemosa* has never been submitted to a chemical examination but Holden (*A. J. P.*, 1880) found in the *A. spinosa* a glucosidal saponin to which he gave the name of *araliin.* It is probable that the official species owes whatever medicinal virtue it may possess to a similar principle.

Uses.—Aralia has been used, especially in domestic practice as an alterative similar to sarsaparilla, in the treatment of rheumatic, syphilitic and cutaneous affections. In medical practice it is employed chiefly in the treatment of pectoral complaints. Its therapeutic value is extremely questionable.

Dose, twenty to thirty grains (1.2–2 Gm.).

Off. Prep.—Fluidextractum Araliæ, *N. F.;* Syrupus Pini Albæ Compositus, *N. F.;* Syrupus Pini Albæ Compositus cum Morphina, *N. F.*

ARAROBA. Br.

ARAROBA [Goa Powder; Crude Chrysarobin]

"Araroba is a substance found in cavities in the trunk of Andira Araroba, *Aguiar,* freed as much as possible from fragments of wood, dried and powdered." *Br.*

Crude Chrysarobin, Goa Powder, Poh di Bahia; Poudre de Goa, *Fr.;* Goa-Pulver, *G.*

Under the name of Chrysarobin, or Araroba, a medicine has long been used in Brazil; it is exported in considerable quantities to Portugal, whence it found its way through the Portuguese colonies into Eastern commerce. It is officially recognized, after being purified, in the British, Swiss and German Pharmacopœias.

It was at one time supposed to be yielded by certain lichens, but was shown by R. A. Monteiro to be obtained from a leguminous tree abundant in the forests of the Brazilian province of Bahia, which was referred by E. M. Holmes to the genus *Cæsalpinia,* but which was determined by studies made in its native forests by J. M. de Aguiar to be a species of *Andira.*

Andira Araroba is a large leguminous tree, attaining a height of 100 feet, with a smooth trunk, common in the province of Bahia, Brazil. The wood is yellowish, with numerous vessels, besides abundant irregular interspaces of lacunæ, in which the chrysarobin is deposited. (See *P. J.*, ix, 755; x, 42, 814.) It is now known that chrysarobin is a result of the breaking down of the walls of the wood elements but the exact nature of the change or the influences that induce it remain to be determined. It is collected by felling the trees, sawing the trunks into segments and splitting them lengthwise. The yellowish araroba powder is then scraped out with the ax and with it splinter and other foreign matter. In this crude condition it is exported, and later it is freed of wood, etc., by sifting, drying and powdering it. The oldest trees yield the largest amount of the powder. The workmen who procure it often suffer severely from irritation of the eyes and face. As first obtained, chrysarobin is stated to be of a pale primrose yellow, but it rapidly darkens with age, so that in commerce it varies from a dull ochre to a dark chocolate or maroon-brown. It is sometimes a rather fine powder, but is usually more or less agglomerated, and not rarely contains fragments of woody tissue.

"The powder varies in color from brownish-yellow to umber-brown. Yields to hot *benzene* not less than 50 per cent. of a substance which, on evaporating the filtrate, drying and powdering the residue, has the character described under ' Chrysarobinum.' " *Br.*

Its taste is bitter. It is insoluble in water and most menstrua, but yields as much as 80 per cent. of its weight to solutions of caustic alkalies and to benzene. Attfield analyzed Goa powder, and found, along with 2 per cent. of resin, 5.5 per cent. of woody fiber, 7 per cent. of bitter extractive, and from 80 to 84 per cent. of what he considered to be chrysophanic acid; but Liebermann and Siedler showed that this was not chrysophanic acid, but a substance easily convertible into the acid, which substance they called *chrysarobin,* and gave to it the formula $C_{30}H_{26}O_7$. (See *Chrysarobinum.*)

For consideration of the therapeutic uses of Araroba, see *Chrysarobin.*

ARGENTI NITRAS. U. S., Br.

SILVER NITRATE Arg. Nit.

" Silver Nitrate when finely powdered and dried to constant weight in the dark over sulphuric acid contains not less than 99.8 per cent. of $AgNO_3$." *U. S.*

" Silver Nitrate, $AgNO_3$, may be obtained by the interaction of nitric acid and silver." *Br.*

Nitrate of Silver, Lunar Caustic; Azotas (Nitras) Argenticus; Azotate d'Argent, *Fr. Cod.;* Nitre lunaire, *Fr.;* Argentum Nitricum Crystallisatum, *P. G.;* Salpetersäures Silberoxyd Silbersalpeter, Silbernitrat, *G.;* Nitrato di argento cristallizzato, *It.:* Nitrato argentico cristalizado, Nitrato de plata, *Sp.*

The U. S. and Br. Pharmacopœias do not give processes for making this salt. The U. S. Pharmacopœia, 1870, gave the following: " Take of Silver, in small pieces, *two troyounces;* Nitric Acid, *two troyounces and a half;* Distilled Water, *a sufficient quantity.* Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved and red vapors cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stoppered bottle. By evaporating the mother-water, more crystals may be obtained." *U. S.*, 1870.

In the above process two details deserve notice. One of these is the direction to cover the materials in the evaporating dish, during the continuance of the reaction, with a glass funnel. This is in order to prevent the escape of fumes and to economize the nitric acid, a portion of which rises in vapor, and, being condensed on the inner surface of the funnel, falls again into the dish. The second detail is the fusion of the salt before being dissolved; the effect is to decompose any copper nitrate that might have been derived from the silver, which, if coin be employed, always contains copper. The heat decomposes the copper nitrate, and the comparatively insoluble oxide is formed, which remains on the filter when the mass is subsequently dissolved in water and filtered, the silver nitrate not being decomposed by the heat used.

A practical method used in Calcutta for separating the copper nitrate depends upon the fact that strong nitric acid only slightly dissolves silver nitrate in the presence of copper nitrate. The silver nitrate is crystallized out from the first solution as long as it can be obtained pure, and the bluish-green mother liquor is evaporated to dryness; the powdered salt, placed in a funnel stopped with asbestos, is percolated with nitric acid (sp. gr. 1.42). This washes out all of the copper nitrate, and the silver nitrate can be freed from the adhering nitric acid by heat. (*P. J.*, 1897, 61.)

During the solution of silver in nitric acid, part of the acid is decomposed and nitric oxide is given off, which becomes red by contact with the atmosphere, and the oxygen oxidizes the silver. This is taken up by the remainder of the acid, and produces silver nitrate in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both hydrochloric and sulphuric acids, should never be used. The hydrochloric acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble silver sulphate. It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which, when washed with solution of ammonia, is perfectly pure. For an account of the manufacture of silver nitrate, see *D. C.*, 1887, p. 3.

Description and Physical Properties.— " Colorless, odorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in the presence of organic matter. One Gm. of Silver Nitrate is soluble in 0.4 cc. of water and in 30 cc. of alcohol, at 25° C. One Gm. is soluble in slightly more than 0.1 cc. of boiling water and in 6.5 cc. of boiling alcohol. It is slightly soluble in ether. When heated in a porcelain crucible to about 200° C., Silver Nitrate melts, forming a faintly yellow liquid, which on cooling, congeals to a pure white, crystalline mass. At a higher temperature it gradually decomposes with the evolution of nitrogen oxides.

"An aqueous solution of the salt (1 in 50) responds to the reactions for silver, page 444. Mix an aqueous solution of the salt (1 in 10) in a test tube with a drop of diphenylamine T.S., and then carefully superimpose it upon sulphuric acid: a deep blue color appears at the line of contact. An aqueous solution of the salt (1 in 10) is clear and colorless, and is neutral to litmus paper. An aqueous solution of the salt (1 in 10) is not colored even faintly blue by the addition of an excess of ammonia T.S. (*copper*).

"**Assay.**—Dissolve about 0.8 Gm. of finely powdered Silver Nitrate, previously dried in the dark over sulphuric acid and accurately weighed, in 50 cc. of distilled water. Add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01699 Gm. of $AgNO_3$. Silver Nitrate may also be assayed by the electrolytic method.

"Preserve in dark amber-colored, glass-stoppered vials, protected from light." *U. S.*

"In colorless tabular crystals. Taste bitter, metallic. Soluble in less than its own weight of *water*, slightly soluble in *alcohol* (90 per cent.); soluble in *ether*, and in *glycerin*. Yields the *reactions* characteristic of silver and of nitrates. 1 gramme dissolved in 15 millilitres of *water* yields with *hydrochloric acid* a precipitate, which, when washed and dried, weighs 0.843 gramme. The filtrate, when evaporated to dryness on a water bath, leaves no appreciable residue. Yields no characteristic *reactions* for lead, copper, iron, or sulphates." *Br.*

The solution stains the skin an indelible black color, and is itself discolored by the most minute portion of organic matter, for which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite compounds with albumin and fibrin. The solution also stains linen and muslin in a similar manner, and hence its use in making the so-called indelible ink. To remove these stains, W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into silver iodide. The iodide is then dissolved by a solution of sodium thiosulphate, made with from half a drachm to a fluidounce of water, or by a moderately diluted solution of potassium hydroxide, and the spots are washed out with warm water. Silver stains may also be taken out by a solution of two and a half drachms of potassium cyanide, and fifteen grains of iodine, in three fluidounces of water. H. Kraetzer recommends, instead of potassium cyanide, a solution of 10 parts ammonium chloride and 10 parts corrosive sublimate in 100 parts of water, with which the stains are said to be removed readily from the hands, and from linen, wool, and cotton without injuring the fabric. (*A. Pharm.*, 1880, 52.) Solutions of calcium or sodium hypochlorite are also useful to remove these stains.

Uses.—When silver nitrate in a pure state is brought in contact with a living tissue, it acts as an escharotic. Owing to the formation of a dense film of coagulated albumin, the depth of its action is very limited; the albuminous coating is at first white, but soon becomes black, owing to the reduction of the silver. Silver nitrate is among the most powerful of the chemical germicides. According to Boer, one part in four thousand is sufficient to destroy the viability of the typhoid bacillus in two hours, and Behring (*D. M. W.*, 1887) found that as dilute as 1 part in 10,000 it was capable of destroying the higher resistant anthrax spores if the exposure was sufficiently long (48 hours). It is antiseptic in proportions of 1 part in 30,000. Despite the fact that it is so easily precipitated it retains a considerable degree of germicidal power even in the presence of large quantities of albuminous material. When applied to the human tissues in dilute solution it is an active astringent; in concentrated form it is mildly caustic, but the depth of its action is very limited because the dense film of silver albuminate which is rapidly formed prevents further penetration.

Although silver nitrate, because of it affinity for proteins, cannot exist unchanged in the blood, when taken into the stomach the silver is absorbed in some form, perhaps as a proteinate. When a non-precipitable salt of silver is introduced into the blood in sufficient quantities it causes convulsions followed by paralysis through its effect upon the spinal cord, weakening of the circulation with pulmonary edema, and respiratory embarrassment. There is, however, no known physiological action which lends any support to its use as a systemic drug.

The most important use of silver is locally as an astringent and germicide, especially in infections of the mucous membranes. The strength employed varies greatly according to the location and nature of the infection, thus in *diphtheria* or *tonsillitis* it may be used as concentrated as 4 or 5 per cent., while in *urethritis* at times it cannot be borne in higher concentrations than one part in ten thousand. In *ophthalmia neonatorum* it is useful either as a prophylactic or a curative. As a preventive the instillation of one or two drops of a 2 per cent.

solution is advised in all cases of suspicious birth. In sluggish *ulcers* its astringent and stimulating effect is often of great value. It has been widely employed as an astringent in treatment of various types of *gastritis,* especially in *ulcer of the stomach.* Colonic injections of silver nitrate in strengths of ten to twenty grains to the quart have been highly lauded not only in *chronic colitis* but also in *dysentery.*

Internally silver nitrate was formerly used to some extent in the treatment of various chronic diseases of the nervous system, as *epilepsy, locomotor ataxia,* etc., but has largely passed out of vogue. The prolonged use internally of silver leads to a peculiar slate blue discoloration of the skin known as *argyria.* This discoloration may also appear on the mucous membrane and is probably due to a deposit of metallic silver. When once produced it is usually permanent, although Yandel has reported its disappearance under a course of potassium iodide. (*N. R.,* July, 1873.) It is possible that methenamine as suggested by Olson (*J. A. M. A.,* 1917, lxix, p. 87) may be of service.

Silver nitrate should always be given in pill, as the solution is decomposed by the liquids of the mouth. It should not be made up into pill with crumb of bread, as this contains common salt, but with kaolin and petrolatum, cacao butter, or other media not readily oxidizable. But, as all organic substances decompose it more or less, Vée proposes the use of inorganic matter, such as potassium nitrate, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass.

When ingested in sufficient dose, silver nitrate is a violent poison, and upon several occasions caused death. The symptoms are those of toxic gastro-enteritis, with marked constitutional disturbances, especially coma, convulsions, paralysis, and profound alterations of the respiration. The treatment of the poisoning resolves itself into the use of the ordinary antidotes (common salt, soap, alkalies, etc.), and the use of stimulants to maintain the circulation if needed.

Silver nitrate is incompatible with most natural waters, on account of the chlorides usually contained in them; with soluble chlorides; with hydrogen sulphide, sulphuric, hydrochloric, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime water, and with astringent infusions. It is sometimes improperly prescribed in pills with tannic acid, by which it is decomposed.

Dose, one-fourth to one-half grain (0.016–0.032 Gm.).

Off. Prep.—Argenti Nitras Fusus, *U. S.* (*Br.*); Argenti Nitras Induratus, *Br.;* Argenti Nitras Mitigatus, *Br.*

ARGENTI NITRAS FUSUS. U. S. (Br.)

FUSED SILVER NITRATE Arg. Nit. Fus. [Moulded Silver Nitrate, Lunar Caustic]

"Fused Silver Nitrate contains not less than 94.5 per cent. of $AgNO_3$." *U. S.*

Argenti Nitras Induratus, *Br.;* Fused Nitrate of Silver; Lapis Infernalis, Argentum Nitricum Fusum; Styli Argenti Nitrici, Crayons d'Azotate d'Argent, *Fr. Cod.;* Azotas (Nitras) Argenticus Fusus, Azotate d'Argent fondu, Pierre Infernale, *Fr.;* Gehärteter Höllenstein, Geschmolzenes Salpetersaures Silberoxyd, Silbernitrat, *G.;* Nitrato di argento fuso, *It.;* Nitrato argentico fundido, Piedra infernal, *Sp.*

"Silver Nitrate, 95 grammes; Potassium Nitrate, 5 grammes. Fuse together, mix and pour into suitable moulds." *Br.*

The U. S. no longer recognizes a method for this preparation; that of the U. S. 1890 was as follows: "Silver Nitrate, 100 grammes; Hydrochloric Acid, 4 grammes. Add the hydrochloric acid to the silver nitrate, contained in a porcelain dish, and melt the mixture at as low a temperature as possible. Stir it well, and pour the melted mass into suitable moulds. Preserve it in dark amber-colored vials, protected from light." *U. S.* 1890. This can be achieved by the addition of various salts as sodium chloride, potassium nitrate, etc. The former method of the U. S. IX followed the suggestion of E. R. Squibb of adding hydrochloric acid whereby silver chloride with formed. In order to keep the stick from becoming discolored during the casting process, it is advisable to add a diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. Edward J. Hughes (*Proc. Penna. Pharm. Assoc.,* 1922, p. 208) finds it advantageous to replace the hydrochloric acid by sodium chloride, using 1.4 grammes of sodium chloride to each 100 grammes of silver nitrate. The fusion takes place quietly without the disagreeable fuming produced by former methods, the moulded product is tough and answers the assay requirements for an official product. In the British process the "toughening" is effected by the addition of 5 per cent. of potassium nitrate. In our opinion, this is not as efficient as is the use of hydrochloric acid.

As the molten salt is capable of penetrating a common crucible, the fusion is performed in a porcelain dish or preferably a casserole, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its boiling over. Sometimes small portions of the liquid are spurted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should not be greased, as the organic matter would partially decompose the fused salt. Stein (*S. W. P.,* 1877) recommends a plan for obtaining sticks of lunar caustic of special diameter or length by taking a glass tube or rod of the required outside diameter and wrapping around it moistened parchment paper, pasting the edges, tying the lower end, and drying. The melted lunar caustic is poured into the paper mould, held upright in a test tube, and allowed to cool by standing. *Elastic crayons* of silver nitrate may be made by taking a laminaria tent one-tenth of an inch (0.002 mm.) in diameter, dipping it into thick mucilage, rolling it in finely powdered lunar caustic, and drying it. (Pajot.)

Moulded silver nitrate, as prepared by the above process is in the form of hard, brittle sticks of the size of a goose quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, through organic matter or conversion through hydrogen sulphide contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Scanlon, who finds that silver nitrate in a clean glass tube hermetically sealed undergoes no change by exposure to light. The sticks often become dark colored and nearly black on the surface, and when broken across, exhibit a crystalline fracture with a radiated surface. Entirely black lunar caustic is sometimes seen in France, which contains about 2 per cent. of potassium nitrate and the same quantity of black manganese oxide. *Heller's caustic pencils* look like ordinary lead pencils, and consist of long, thin sticks of lunar caustic, encased in wood; they may be sharpened like lead pencils, and the point protected by a cap to prevent injury when not in use.

Description and Physical Properties.—"A white, hard, odorless solid, generally in the form of pencils or cones, showing a fibrous fracture and becoming gray or grayish-black on exposure to light. Fused Silver Nitrate, with the exception of about 5 per cent. which is silver chloride, possesses the solubility described under *Argenti Nitras.* A filtered, aqueous solution of Fused Silver Nitrate (1 in 10) is neutral to litmus paper, and conforms to the tests for identity and purity under *Argenti Nitras.*

"**Assay.**—Add about 0.8 Gm. of Fused Silver Nitrate, accurately weighed, to 50 cc. of distilled water, and, when the silver nitrate has dissolved, filter the solution. Thoroughly wash the filter and sediment with distilled water, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. to the mixed filtrate and washings, and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01699 Gm. of $AgNO_3$. Fused Silver Nitrate may also be assayed by the electrolytic method.

"Preserve in dark, amber-colored, glass-stoppered vials, protected from light." *U. S.*

"White or grayish-white cylindrical rods or cones. Freely soluble in *water,* but only sparingly in *alcohol* (90 per cent.). Yields the *reactions* characteristic of silver, of potassium, and of nitrates. 1 gramme, dissolved in 15 millilitres of *water,* yields with *hydrochloric acid* a precipitate which, when washed and dried, weighs 0.8 gramme, and the filtrate when evaporated leaves a white residue." *Br.*

Uses.—Lunar caustic affords a convenient method for applying silver nitrate locally in the concentrated form, especially where combined escharotic and germicidal action is desired. It is of special service in *aphthous stomatitis, exuberant granulations, chancroids,* and various other *ulcers.* The mode of application consists in dipping the stick into distilled water and applying to the part for a greater or less period of time according to the degree of action which is desired.

The moulded silver nitrate has also been used as a counter-irritant. If it be rubbed gently back and forth over the moistened skin until the latter assumes a grayish color, it generally vesicates, usually with less pain than is produced by cantharides. As a counter-irritant it has been employed in the treatment of violent inflammations of the subcellular tissue and it is asserted that it will sometimes avert a felon or an *epididymitis.*

ARGENTI NITRAS MITIGATUS. Br.

MITIGATED CAUSTIC

Mitigated Silver Nitrate [Argenti Nitras Dilutus, U. S. 1890, Diluted Silver Nitrate, Mitigated Caustic] Silver and Potassium Nitrate; Lapis infernalis nitratus; Crayons d'Azotate d'Argent Mitigé, Pierre Infernale diluée, *Fr.;* Argentum Nitricum cum Kalio nitrico, *P. G.;* Salpeterhaltiges Silbernitrat, Salpeterhaltiger Höllenstein, *G.;* Nitrato di argento fuso con nitrato di potassio, *It.;* Nitrato argentico mitigado, Piedra infernal mitigada, *Sp.*

"Silver Nitrate, 20 *grammes;* Potassium Nitrate, 40 *grammes.* Fuse together, mix and pour into suitable moulds." *Br.*

The introduction of this preparation grew out of the frequent demand for a fused silver nitrate which would not be so severe in its action as the pure article. The diluted nitrate of the U. S. P. VIII was the same as the British preparation, 33 per cent.

Properties.—"White or greyish-white cylindrical rods or cones. Freely soluble in *water,* but only sparingly in *alcohol* (90 per cent.). Yields the *reactions* characteristic of silver, of potassium, and of nitrates. 3 grammes, dissolved in 15 millilitres of *water,* yield with *hydrochloric acid* a precipitate which, after washing with hot *water* and drying, weighs 0.843 gramme." *Br.*

Uses.—This preparation is used only externally. It is similar in its action to the fused nitrate, but less energetic.

ARGENTO-PROTEINUM FORTE. U. S.

STRONG SILVER-PROTEIN

Arg.-Prot. Fort. [Strong Protargin]

"A compound of silver and protein, containing not less than 7.5 and not more than 8.5 per cent. of silver (Ag)." *U. S.*

Silver Proteinate; Strong Protein Silver.

In the attempt to produce a substance which would have the desirable disinfectant properties of the silver salts but be free from the objectionable irritant action of the nitrate, chemists have produced a large number of compounds containing silver—or some salt of it—at least partly in colloid suspension with more or less protein matter. These compounds are all of them much weaker germicides than the nitrate, but some possess considerable disinfectant power. They are also less actively astringent or irritant and have a distinct field of usefulness. They differ very widely among themselves both in their physical and biological properties. As shown by Pilcher and Sollmann (*J. Lab. Clin. Med.*, 1923, viii, p. 301 and 1924, x, p. 38) there seems to be a rather sharply defined separation of these compounds into several groups; one of these, containing smaller amounts of total silver and having relatively low specific gravities, constitutes the *Argento-Proteinum Fortius* of the U. S. P.; another group, containing from 20 per cent. of silver upwards, darker in color and more viscid, is the *Argento-Proteinum Mite.* There are also corresponding biological differences, the first type being more actively germicidal and more irritant. Pilcher and Sollmann believe that the differences in biological properties depend upon the relative proportion of ionic silver present, but Giesy (*J. A. Ph. A.*, 1925, xiv, p. 8) has pointed out that they have confused the difference between ionic and ionizable silver. However, the classification corresponds fairly accurately with clinical experience.

There has been considerable discussion as to the state of the silver in these compounds; some believe that they are colloidal suspensions of silver oxide, others that the silver is largely in a metallic state, while still others believe it chemically combined with the protein.

Smith and Giesy (*J. A. Ph. A.*, 1925, xiv, p. 10) find that the difference between these two groups is not so much in the proportion of ionic silver present, but is better measured by the proportion of silver more ionizable than silver chloride (see also Kolthoff, *J. A. Ph. A.*, xiv, p. 183). In the first group some 75 per cent. of the silver can be changed, according to Giesy, into a less ionizable form by sodium chloride. In the second group, the mild proteinates, practically none of the silver ions are removed by the chlorides, although they are by the iodides.

Kolthoff (*J. A. Ph. A.*, 1925, xiv, p. 183) from a potentiometric study of silver protein concludes that the reason that hydrochloric acid does not cause a visible precipitate, is not on account of the failure to form silver chloride, but because the silver chloride formed remains in colloidal solution.

The U. S. P. test on yeast fermentation is not intended as an evidence of antibacterial power but merely as a biological differentiation between allied drugs.

The definition given in the Pharmacopœia of silver protein has purposely been made broad enough to admit several proprietary preparations. It represents a group of compounds rather than any individual drug. In a way this may seem unfortunate, because there is not to be expected an absolute uniformity in their effects, but the present evidence indicates that there may be as wide differences between different samples of the same brand as among the various members of a group.

Description and Physical Properties.—" A brown, odorless powder, usually somewhat hygroscopic. Strong Silver-Protein is freely soluble in water, but almost insoluble in alcohol, chloroform, and ether.

" Heat about 0.2 Gm. of Strong Silver-Protein in a porcelain crucible until all carbonaceous matter is burned off, warm the residue with 1 cc. of nitric acid, dilute with 10 cc. of distilled water, and add hydrochloric acid: a white precipitate is produced which dissolves in ammonia T.S. The addition of 2 cc. of a 1 per cent. aqueous solution of sodium chloride to 10 cc. of an aqueous solution of Strong Silver-Protein (1 in 100) causes no turbidity. Ferric chloride T.S. added to its aqueous solution (1 in 100) discharges the dark color, and a precipitate is gradually produced. With mercuric chloride T.S. a white precipitate is formed, and the supernatant liquid becomes colorless or nearly so.

" When tested by the method described below, Strong Silver-Protein permits abundant gas formation when 0.6 cc. of its aqueous solution (1 in 200) is added to 20 cc. of the yeast-sugar mixture, and at most only one bubble of gas is formed when 1.5 cc. of the same strength solution is added to 20 cc. of the yeast-sugar mixture. If the yeast is more active, as determined by the control with silver nitrate described below, a proportionately larger volume of the Strong Silver-Protein solution is required, or if the yeast is less active, a proportionately smaller volume of the Strong Silver-Protein solution is required. Triturate an aqueous solution of sucrose (1 in 10) with 4 per cent. of its weight of compressed yeast. Place four 20 cc. portions of this mixture in test tubes. To one test tube add 0.6 cc. of an aqueous solution of Strong Silver-Protein (1 in 200), mix well, immediately fill a small test tube with this mixture and invert it into the larger test tube, being careful that no air bubbles rise into the small test tube. To the second test tube add 1.5 cc. of an aqueous solution of Strong Silver-Protein of the same concentration; to the third tube add 0.6 cc. of an aqueous solution of silver nitrate (1 in 2000), and to the fourth tube add 1 cc. of the same silver nitrate solution. Fill smaller test tubes with each solution and proceed as directed for the first tube. Place all four of the test tubes in a bath at 38° C. and maintain this temperature for one hour. At the end of this period, the first and third of the smaller tubes should show abundant gas formation, the second smaller tube should show not more than a bubble of gas, and the fourth tube should show not more than about 1 cc. of gas. If the third tube shows no gas, repeat the tests reducing the concentration of all of the silver solutions to one-half, and if there should still be no gas formation in the third tube, again repeat the tests, reducing the concentration of all of the silver solutions by one-third. If the fourth tube in the first series of tests contains more than about 1 cc. of gas, repeat the tests, but increase the concentration of all of the silver solutions by one-third, and if this also produces more than 1 cc. of gas in the fourth tube, again repeat the tests, increasing the concentration of all of the silver solutions by one-half (distinction from *Mild Silver-Protein*).

" **Assay.**—Ignite about 2 Gm. of Strong Silver-Protein, accurately weighed in a porcelain crucible until all of the carbon is burned off. Transfer as much as possible of the residue to a beaker, add to the crucible 5 cc. of nitric acid, warm to dissolve any adhering silver, and transfer the solution to the beaker with the aid of a little distilled water. Cover the beaker, and heat on a water bath until all of the metallic silver is dissolved, adding a little more nitric acid, if necessary. Filter into a flask, wash the insoluble residue thoroughly with distilled water, cool, and dilute with distilled water, if necessary, to about 50 to 75 cc. Add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01079 Gm. of silver.

" Preserve in well-closed containers, protected from light. *Caution.—Solutions of Strong Silver-Protein should be freshly prepared and dispensed in amber-colored bottles.*" *U. S.*

Uses.—The stronger silver protein has a very pronounced germicidal effect. In a general way it would probably be approximately correct to say that this group of drugs had a bactericidal power of about one-half or one-third that of phenol. This seems insignificant when we consider the extraordinary disinfectant power of silver nitrate. Even when we consider the degree of dilution necessary to avoid local irritation, it must be conceded that the silver nitrate still exceeds silver protein in germicidal power, but there is reason to believe that the silver protein solution retains its antibacterial powers better in the face of the bodily secretions than the nitrate. Clinical experience indicates that a higher degree of germicidal effect without undue irritation is obtainable over mucous membranes with silver protein than is possible from silver nitrate.

Silver proteins are used in medicine solely for their local disinfectant powers, especially of infections of mucous membranes, such as *acute coryza, tonsillitis, conjunctivitis, urethritis* and the like. In acute urethritis it is employed in strengths of from 1 to 2 per cent. In tonsillitis it is commonly applied as a 10 per cent. solution and occasionally even stronger.

This silver protein, if used in strong solution—10 per cent. or upwards,—has a slight irritating action suggestive of silver nitrate, but differs from silver nitrate even when in strong solution, in lacking astringent properties.

Several cases of local argyria, especially of the eyelids, have been reported from the topical use of silver protein. Olson (*J. A. M. A.*, 1917, lxix, p. 87) has made a literary and experimental study of this condition and presents evidence suggesting the value of methenamine for removing these discolorations.

ARGENTO-PROTEINUM MITE. U. S.

MILD SILVER-PROTEIN

Arg.-Prot. Mit. [Mild Protargin]

" Silver rendered colloidal by the presence of or combination with protein. It contains not less than 19 per cent. and not more than 25 per cent. of silver (Ag)." *U. S.*

See remarks under *Argento-proteinum Fortius.*

Description and Physical Properties.—" Dark brown or almost black shining scales or granules. It is odorless, and is frequently hygroscopic. Mild Silver-Protein is freely soluble in water, but almost insoluble in alcohol, chloroform, and ether.

" Heat about 0.1 Gm. of Mild Silver-Protein in a porcelain crucible until all carbonaceous matter is burned off, warm the residue with 1 cc. of nitric acid, dilute with 10 cc. of distilled water, and add hydrochloric acid: a white precipitate is produced which dissolves in ammonia T.S. The addition of 2 cc. of an aqueous solution of sodium chloride (1 in 100) to 10 cc. of an aqueous solution of Mild Silver-Protein (1 in 100) causes no turbidity. Ferric chloride T.S. added to its aqueous solution (1 in 100) discharges the dark color and a precipitate is gradually produced. With mercuric chloride T.S. a white precipitate is formed and the supernatant liquid becomes colorless or nearly so. When tested by the method described under *Argento-Proteinum Fortius,* 0.8 cc. of an aqueous solution of Mild Silver-Protein (1 in 20) permits abundant gas formation (distinction from *Strong Silver-Protein*).

" **Assay.**—Proceed as directed under *Argento-Proteinum Fortius,* using about 1 Gm. of Mild Silver-Protein.

" Preserve in well-closed containers, protected from light. *Caution.—Solutions of Mild Silver-Protein should be freshly prepared and dispensed in amber-colored bottles.*" *U. S.*

Uses.—As remarked under *Argento-proteinum Fortius* the Pharmacopœial definition represents a group rather than an individual compound. The various individuals that belong to the type of mild silver proteins—the term " mild " applies both to their lack of irritant qualities and their antibacterial powers—differ even more widely among themselves than the stronger type. Indeed different specimens of the same brand seem to differ very widely in their germicidal properties. It is not obvious, however, that there is any very material difference in their therapeutic value. Their chief therapeutic importance is not as germicides—that is, to destroy bacteria—but as antiseptics, to inhibit the growth of bacteria. Some writers go so far as to maintain that the therapeutic effect of this group of silver compounds is largely, if not chiefly, due to mechanical factors. Their peculiar colloidal state makes them of great value as mechanical cleansers of mucous membranes. They differ materially from the stronger proteins, in that even in concentrated solution they are practically non-irritant.

They are used in the same diseases as the stronger silver proteins, but preferred in those very acute types of catarrh in which it is important to sedulously avoid any irritation of the mucous membrane. Ordinarily they are applied in strengths of from 10 to 25 per cent., or sometimes up to 50 per cent.

For information concerning the individual brands of silver protein see under *Silver Compounds,* Part II.

ARGENTUM

SILVER

Argentum purificatum; Argent raffiné, Argent, *Fr.;* Argentum Foliatum, *Fr. Cod., P. G.:* Silber, Raffinirtes Silber, *G.;* Argento, *It.;* Plata, *Sp.*

Silver is found at times in the metallic state, usually crystallized, also associated with gold, antimony, arsenic, or mercury; but usually it occurs as a sulphide, pure or mixed with other sulphides, as those of copper, lead, and antimony. It is sometimes found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru and our own Rocky Mountain States and Territories; the richest in Europe are those of Norway, Hungary, and Transylvania. Mines have been opened and profitably worked in California and Nevada but at present it is chiefly Colorado and Montana which furnish the great bulk of the American silver production. Idaho, Utah, and Arizona also contain very rich silver deposits. The principal ore is the sulphide. The mineral containing silver which is most disseminated is argentiferous *galena,* which is lead sulphide containing a little silver sulphide. Argentiferous galena exists in several localities in the United States. Native silver is associated, in small quantities, with the native copper of the Lake Superior region, and a little of it has come into the market. The two metals, though more or less mixed, are yet quite distinct, never being alloyed to any considerable extent, showing conclusively that the deposits have not undergone igneous fusion at any time, but that the metals have deposited from solution.

Extraction.—Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation.* When the ore is principally silver sulphide, it is mixed with a tenth of sodium chloride and roasted in reverberatory furnaces. As fast as the sulphide is oxidized to sulphate, this reacts with the sodium chloride, forming silver chloride and sodium sulphate. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, one-third of its weight of water, and about one-seventeenth of iron in flat pieces, and subjected for sixteen or eighteen hours to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as iron chloride, while the reduced silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leather bags, through the pores of which the excess of mercury passes, a solid amalgam being left behind. This is then subjected to heat in a distillatory apparatus, by means of which the mercury is separated from the silver, which is left in a porous mass. In Peru and Mexico the process is similar to that above given, common salt and mercury being used; but slaked lime and iron sulphide are also employed, with little effect.

When argentiferous galenas are worked for the silver they contain, they are at first reduced, and the argentiferous lead obtained is fused on a large, oval, shallow vessel called a test, and exposed to the blast of a bellows, whereby the lead is oxidized, half vitrified, and driven off the test in scales, in the form of litharge. The operation being continued on successive portions of argentiferous lead, the whole of the lead is separated, and the silver, not being oxidizable, accumulates on the test as a brilliant fused mass, until its amount is sufficient to be removed. The time required for the separation is much abridged by the process of Pattinson. This consists in allowing the melted alloy to cool slowly, and separating the crystals which first form, consisting mainly of lead, by means of a perforated ladle. The residue is a very fusible alloy of lead and silver, in which the latter metal is in large proportion, and from which it can be easily separated by cupellation or other means. In recent years much gold and silver have been extracted from tailings and so-called "slimes" by the cyanide process and most recently by the "oil flotation" process.

Properties.—Silver is a white metal, very brilliant, tenacious, melleable, and ductile. In malleability and ductility it is inferior only to gold. It is harder than gold, but softer than copper. Its atomic weight is 107.88, symbol Ag, and sp. gr. from 10.4 to 10.5. What is termed "molecular silver" is obtained as a very fine powder, by reducing freshly precipitated silver chloride with formaldehyde in the presence of potassium carbonate. *"Colloidal silver"* is obtained by heating to 100° C. silver citrate in a stream of hydrogen or by passing an electric current between silver electrodes in water. It dissolves in water to a red solution which does not dialyze. Both these allotropic forms are converted into ordinary silver by fusion. (For further description, see Part II.) Silver forms but one well-characterized oxide. Exposed to a full red heat, it enters into fusion, melting at 954° C., and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish of silver sulphide by the action of hydrogen sulphide in the atmosphere, from which it may be freed by washing it with a strong solution of potassium cyanide, and, as soon as it becomes bright, washing it with water and drying it. It is entirely soluble in diluted nitric acid. If any gold be present, it will remain undissolved as a dark-colored powder. From the nitric solution the whole of the silver may be thrown down by sodium chloride, as a white precipitate of silver chloride, characterized by being completely soluble in ammonia. If the remaining solution contain copper or lead, it will be affected by hydrogen sulphide. "The solution, deprived of silver by means of sodium chloride, and filtered, is not colored, *or but slightly so,* and is not precipitated by hydrosulphuric acid." *U. S.* 1870. "If ammonia be added in excess to a solution of the metal in nitric acid, the resulting fluid exhibits neither color nor turbidity" (*Br.* 1885); proving the absence of copper, lead, and other metals. "10 grains dissolved in a little nitric acid, the solution diluted with water, and diluted hydrochloric acid added in slight excess, yields a white precipitate which, when thoroughly washed, dried, and heated, weighs 13.25 grains." *Br.* 1885.

ARMORACIÆ RADIX. Br.

HORSERADISH ROOT

"Horseradish Root is the fresh root of Cochleria Armoracia, *Linn.*, collected from cultivated plants." *Br.*

Armoracia, *Br.* 1864; Radix Raphani Rusticani Raifort *Fr. Cod.*; Moutarde des Moines, Radis de Cheval, Cran de Bretagne, *Fr.*; Meerrettig, *G.*; Rabano rusticano (Raiz de), *Sp.*

Cochlearia Armoracia L. (also known as *Roripa Armoracia* L., Hitch. and *Radicula Armoracia* L., Robinson) a member of the *Cruciferæ,* is a native of the marshy districts of Eastern Europe. It is cultivated very largely for its roots which are used as a condiment, being considered stimulating to the digestive organs. It has escaped from our gardens, growing in moist grounds, especially along streams. The root of this plant is perennial, sending up numerous very large radical leaves from the midst of which a round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-shaped, wavy, scalloped on the edges, sometimes pinnatifid, and stand upon strong footstalks; those of the stem are much smaller, oblong or lanceolate, sessile, sometimes divided at the edges, sometimes almost entire. The flowers are white, and arranged in terminal and axillary panicles of racemes. The fruit is a silicle.

The root, which is most active in early spring and autumn, is long, conical at top, then nearly cylindrical for some inches, at last tapering, of a strong, pungent, odor when scraped or bruised, and of a hot, biting, somewhat sweetish, and sometimes bitterish taste. "Nearly cylindrical, except at the crown, where it is somewhat enlarged, and marked with closely approximated semi-amplexicaul leaf-scars. Diameter from twelve to twenty-five millimetres, length commonly thirty centimetres or more; pale yellowish-white or brownish-white externally, whitish within. Inodorous when unbroken, but yielding a characteristic pungent odor when scraped or bruised; taste very pungent." *Br.*

Its virtues depend upon a *volatile oil,* which is dissipated by drying, the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The oil may be obtained by distillation with water. It is colorless or pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Hubatka considers it as identical with the volatile oil of mustard. He combined it with ammonia and obtained crystals of *thiosinamin.* $NH_2.CS.N(C_3H_5)H$, which agreed with that produced from mustard oil. (*J. P. C.,* 3e sér., v, 42.) According to Gutret, only six parts of it are obtained from 10,000 of the root. Besides this principle, the fresh root contains, according to the same chemist, a little resin in minute quantity, sugar, extractive, gum, starch, albumen, acetic acid, calcium sulphate and acetate, water and lignin. From observations made by F. L. Winckler, it may be inferred that like mustard it contains *potassium myronate* which in the presence of water is decomposed by an enzyme, also existing in the root, and water, to produce the volatile oil. (See *Sinapis.*) Horseradish when distilled with alcohol yields none of the oil. Buried in cool sand the root may be kept for some time without material deterioration.

It is said that if to the powder of the dried root which has become apparently inert, the emulsion of white mustard seed containing myrosin be added, it re-acquires its original irritant properties; so that it is the ferment myrosin and not the potassium myronate which is injured by drying. Hence the powdered root may be added with advantage to mustard in preparing cataplasms, pediluvia, etc. (*J. P. C.,* xxvii, 268.)

The French Codex contains a formula for *compound syrup of horseradish* under the name of *Sirop de Raifort Composé.* It was formerly called *Sirop Antiscorbutique.*

Uses.—Horseradish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion.

Dose, fifteen to thirty grains (1–2 Gm.) or more, grated or cut into small pieces.

Off. Prep.—Spiritus Armoraciæ Compositus, *Br.*

ARNICA. N. F. (Br.)

ARNICA Arnic. [Arnica Flowers]

"Arnica is the dried flower-head of *Arnica montana* Linné (Fam. *Compositæ*). Arnica contains not more than 3 per cent. of foreign organic matter." *N. F.*

"Arnica Flowers are the dried flower-heads of Arnica montana, *Linn.*" *Br.*

Arnicæ Flores, *Br.;* Leopard's Bane, Wolf's Bane, Mountain Tobacco; Fleurs d'Arnique, *Fr.;* Flores Arnicæ, *P. G;* Wohlverleihblüthen, Arnicablüthen, Arnika, Blutblume, Gemsblume, Fallkraut, *G.;* Fiori di arnica, *It.;* Flor de arnica, *Sp.*

Arnica montana is a perennial herbaceous plant, having a woody, brownish, horizontal rhizome, from 2 to 10 cm. long, and 0.5 to 5 mm. thick, ending abruptly, and sending forth numerous slender fibers of the same color. The stem is about 3 dm. high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are bright green, and somewhat pubescent on their upper surface. The flower-heads are yellow.

This plant is a native of the mountainous districts of western and central Europe, and is found, according to Nuttall, in the northern regions of this country, west of the Mississippi. It has been introduced into England, and might no doubt be cultivated in the United States. The flowers, leaves and root are employed; but the flowers only are official. In the Swiss and German Pharmacopœias the definition of arnica flowers is restricted to the flowers separated from the receptacles, this being done as the latter contain the larvæ of *Trypeta arnicivora.* On the other hand the Austrian Pharmacopœia permits the use of the entire flower heads, but the receptacles containing larvæ must be removed.

Description and Physical Properties.—"*Unground Arnica.*—Consisting chiefly of the tubular and ligulate flowers, usually with the involucre and receptacle present; involucral bracts narrowly lanceolate, about 1 cm. long, dark green and pubescent; receptacle slightly convex, deeply pitted and densely short hairy; ray flowers yellow, the ligulate portion up to 2 cm. long, more or less folded lengthwise, 3-toothed, 7- to 12-veined, pistillate; tubular flowers perfect, reddish yellow, stamens without a tail-like appendage; the achenes spindle shaped, 5 to 7 mm. long, dark brown, finely striate; glandular pubescent and surmounted by a pappus a little longer than the achene and composed of a single circle of nearly white barbellate bristles. Odor characteristic and agreeable, taste bitter and acrid.

"*Powdered Arnica.*—Yellowish brown; pollen grains numerous, 0.025 to 0.035 mm. in diameter, spherical triangular in section and spinose; non-glandular hairs of three kinds, either unicellular, 4- to 6-celled, or consisting of a pair of unicellular hairs with numerous pores on the dividing wall; glandular hairs of three kinds, either with a large unicellular stalk and a unicellular glandular head, or with a 4-celled stalk and a unicellular glandular head, or a stalk of a double row of 5 cells which may be more or less broken and a 2-celled, glandular head; pappus consisting of a multicellular axis with unicellular branches." *N. F.*

"Receptacle nearly flat, bristly, with two rows of dark-green, linear-lanceolate, acute, hairy bracts. Each ray-floret possesses a much shrivelled dark yellow ligulate corolla which, after expansion in water, exhibits from eight to twelve veins and three terminal teeth. Disc-florets numerous, yellow. Fruits slender, shrivelled, with numerous appressed hairs, and crowned with a single row of stiff, whitish, barbed bristles. Slight aromatic odor; taste bitter and acrid." *Br.*

Arnica flowers of commerce are not infrequently admixed with and substituted by other composite flowers. Farwell states that the heads of *Lapachis columnaris* T. et G., a western composite, have been offered in large quantities for arnica. Hartwich has recently found a sample of arnica adulterated with the flowers of the common dandelion. Beilstein reported having found in one lot approximately 90 per cent. of the flowers of *Inula.* The following flowers also have been used: *Anthemis tinctoria* L., *Calendula officinalis* L., *Doronicum Pardalianches* L., *Inula britannica* L., *Scorzonera humilis* L., *Heterotheca inuloides.* The first three of these are distinguished by the fact that the achenes do not have any pappus. In *Inula britannica* the receptacle is naked and the ligulate flowers are four-nerved. In *Scorzonera* the flowers are all ligulate and the pappus is feather-shaped. In *Heterotheca inuloides* the florets have an inner long pappus and an outer short pappus.

The rhizome was formerly official in both the British and U. S. Pharmacopœias and was described by the latter as follows:

"Rhizome about 5 Cm. long and 3 or 4 Mm. thick; externally brown, rough from leaf-scars; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter." *U. S.,* 1890.

It appears to contain the same active constituents as the flowers.

The *arnicin* of Walz (*N. Jahrb. Pharm.,* xiii), extracted from both the root and the flowers, is an amorphous yellow mass of acrid taste, slightly soluble in water, freely in alcohol or ether, and dissolving also in alkaline solutions. It is precipitable from its alcoholic solution by tannic acid or by water. Walz assigns to arnicin the formula $C_{20}H_{30}O_4$; other chemists that of $C_{35}H_{54}O_7$. Arnicin has not been proved to be a glucoside, although it is decomposed by diluted acids. Sigel (1873) obtained from dried arnica root about ½ per cent. of essential oil, and 1 per cent. from the fresh; the oil of the latter had a sp. gr. of 0.999 at 18° C. The oil was found to be a mixture of various bodies, the principal being the *dimethyl ether of thymohydroquinone,* $C_{10}H_{12}(OCH_3)_2$, boiling at about 235° C., and with this, *phloryl isobutyrate* to the extent of one-fifth of the oil, and the methyl ether of a phlorol. (*Pflanzenstoffe,* 2d ed., p. 1530.) Kondakow confirmed the results of Sigel's investigations. (*J. P. C.,* 1910, ii, 79.) (See also Gildemeister and Hoffmann, *Die Aetherische Oele,* p. 900.) The water from which the oil separates contains isobutyric acid, probably also a little angelic and formic acids, but neither capronic nor caprylic acid, which had been pointed out by Walz. Arnica root contains about 10 per cent. of inulin. (*Pharmacographia,* 2d edition, p. 391.) Klobb reported the presence in arnica flowers of a colorless, crystalline body which he at first named *arnisterin,* but in 1905 he changed its name to *arnidiol.* (*Ph. Ztg.,* 1905, xl, p. 846.)

Uses.—Arnica is an active irritant, which is capable, when taken in overdose, of producing symptoms of violent toxic gastro-enteritis, with great nervous disturbance, reduction or increase of the pulse rate, and collapse. In a number of cases of severe or even fatal poisoning by it, the symptoms have been burning pains in the stomach, vomiting, choleraic diarrhea, giddiness, intense muscular weakness, dilated pupils, finally complete insensibility and collapse. In some cases the disturbances of the gastro-intestinal canal have been absent, and the symptoms have chiefly been of cerebral origin. An ounce of the tincture has produced serious although not fatal, symptoms.

Arnica has been used in Germany in the treatment of *palsies* and various other diseases, but we have very little positive knowledge concerning its action upon the system, and there is no sufficient reason for believing that it is valuable in the treatment of internal diseases. It is largely employed externally in the treatment of *bruises* and *sprains,* generally in the form of the tincture.

The powdered flowers and leaves are sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. A tincture of the root was official in the British Pharmacopœia, 1898.

Dose, of the flowers, one to two grains (0.6–1.2 Gm.).

Off. Prep.—Tinctura Arnicæ, *N. F.* (*Br.*) (from flowers); Fluidextractum Arnicæ, *N. F.*

ARSENI IODIDUM. U. S. (Br.)

ARSENOUS IODIDE Arsen. Iod. [Arsenic Tri-iodide]

"Arsenous Iodide, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of AsI_3." *U. S.* "Arsenious Iodide, AsI_3, may be obtained by the direct combination of iodine and arsenium, and purification of the product by crystallization." *Br.*

Arsenii Iodidum, *Br.;* Arsenici Iodidum, *U. S.* 1870; Iodide of Arsenic, Arsenious Iodide; Iodure d'Arsenic, *Fr.;* Arsenicum jodatum, Arsenik Jodür, Arsentrijodid, *G.*

This iodide was introduced into the U. S. Pharmacopœia for the purpose of preparing the solution of arsenous and mercuric iodides. It may be made by the direct combination of its constituents, with the aid of a gentle heat, but this form readily decomposes, the iodine subliming and condensing in crystals upon the upper portion of the bottle, containing it. The orange red crystalline powder, now official, is much more permanent.

Nickle's process enables the operator to obtain the salt in a crystalline condition. Arsenic and iodine in equivalent proportions are heated together with carbon disulphide in a flask, to which an upright condenser is attached, until the iodine color disappears. The solution is then evaporated to the crystallizing point.

In the *B. Chem. G.,* 1881, 2643, may be found a process for obtaining this salt chemically pure, by making a hot solution of arsenic trioxide in hydrochloric acid, and mixing it with a concentrated solution of potassium iodide, whereupon the triiodide separates as a crystalline powder; this may be washed with hydrochloric acid, sp. gr. 1.120, until a portion of the washings on evaporation ceases to leave a residue of potassium chloride.

Description and Physical Properties.—"An orange-red, inodorous, crystalline powder, stable when protected from direct sunlight and kept in a cool place. *Caution.—Arsenous Iodide is extremely poisonous.*

"One Gm. of Arsenous Iodide is soluble in about 12 cc. of water at 25° C., with partial decomposition. It is soluble in alcohol, chloroform, ether, and carbon disulphide. A freshly prepared aqueous solution of the salt is colorless, but upon standing it gradually decomposes with the formation of arsenous and hydriodic acids and becomes yellow due to the liberation of iodine. No loss of iodine occurs when dry Arsenous Iodide is heated on a water bath, but at higher temperatures it volatilizes.

"An aqueous solution of Arsenous Iodide (1 in 50) responds to the reactions for arsenous compounds, and for iodides. When volatilized, Arsenous Iodide leaves not more than 0.5 per cent. of residue.

"**Assay.**—Proceed as directed under the assay for iodides, using about 0.5 Gm. of Arsenous Iodide, previously dried to constant weight over sulphuric acid and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.01519 Gm. of AsI_3.

"Preserve in amber-colored, glass-stoppered vials, in a cool place, protected from light." *U. S.*

"Small orange-colored crystals. Soluble in *water,* and in *alcohol* (90 per cent.). The aqueous solution is acid to *litmus,* and yields the *reactions* characteristic of arsenic and of iodides.

Heated in a test-tube it entirely volatilises, violet vapors of iodine being set free." *Br.*

It has a tendency to decompose even at ordinary temperatures, iodine separating and volatilizing, oxygen being absorbed and arsenic trioxide formed.

Uses.—Following the suggestion of Biett, arsenous iodide has been somewhat extensively used in the treatment of *lupus* and other skin conditions in which a powerful stimulant is desired; Biett employed the ointment of the strength of three grains to the ounce. The iodide has also been given internally as an alterative, in *cancer,* in *scrofula, lepra,* etc., and probably does not differ in its action from other preparations of arsenic. In large doses it acts as a violent gastro-intestinal irritant and poison.

Dose, one-twentieth to one-fifth grain (0.003–0.012 Gm.).

Off. Prep.—Liquor Arseni et Hydrargyri Iodidi, *U. S.* (*Br.*).

ARSENI TRIOXIDUM. U. S. (Br.)

ARSENIC TRIOXIDE Arsen. Triox. [Arsenous Oxide, White Arsenic]

"Arsenic Trioxide, when dried to constant weight at 100° C., contains not less than 99.8 per cent. of As_2O_3. *Note.—Powdered Arsenic Trioxide when administered in solid form, as in powders, tablets, and pills, must consist of particles not greater than* 0.0125 *mm. in diameter.*" *U. S.*

"Arsenious Anhydride may be obtained by roasting certain arsenical ores, and contains not less than 99.8 per cent. of arsenious oxide, As_4O_6." *Br.*

Acidum Arseniosum, *Br.;* Acidium Arsenosum, Arsenous Acid; Arsenous Anhydride; Arsenicum Album, *Ed.;* Anhydride arsénieux, *Fr. Cod.;* Arsenic blanc, Fleurs d'Arsenic, *Fr.;* Acidum Arsenicosum, *P. G.;* Arsenigesäure, Arsenichte Säure, Weisser Arsenik, *G.;* Anidride arseniosa, Acido arsenioso, Arsenico bianco, *It.;* Anhidrido arsenioso, Arsenico blanco, *Sp.;* Arsenik, Dan., *Swed.*, *Pol.*

Arsenic trioxide is found native in octahedral crystals, called *arsenalite,* or as monoclinic crystals, called *clandetite.* It is always formed when arsenic or arsenical minerals are heated or roasted in the presence of air, and is a by-product in a number of metallurgic operations.

Arsenic trioxide is prepared in Bohemia and Saxony, where it is procured on a large scale as a collateral product during the smelting of cobalt ores which are almost invariably accompanied by arsenic, and in England from the mineral *arsenopyrite,* also called *mispickel* or *arsenical iron,* which is associated with the ores of tin and copper. Most of the arsenous oxide produced in the United States is from this latter mineral and much of it comes from Ontario from the residues left after treating gold ores. The German process is that usually quoted as the older and better known. According to this the ores are roasted in reverberatory furnaces with long horizontal flues. The arsenic is converted by combustion into arsenic trioxide, which rises in vapor and condenses on the sides of the flues. In this state it is impure, and requires a second sublimation, which is performed in cast iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenic trioxide is thrown in through the opening, which is immediately stopped. This portion being sublimed, a second portion is introduced in a similar manner. Finally, the vessels are allowed to cool; and upon removing the heads the purified oxide is found attached to them, in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken into fragments of a convenient size, and thus enter commerce. The arsenic trioxide so obtained is generally packed in casks, containing from two to five hundred pounds and is shipped principally from the ports of Hamburg and Bremen. The English process differs somewhat in its details, and essentially in its final product, which is fine and crystalline rather than amorphous. In this process the crude arsenic of the first sublimation is refined by introducing it into another furnace or series of furnaces, where it is again volatilized by the heat. When it condenses in the long series of chambers through which the vapors are carried, it is, if the process be fully successful, in the form of a perfectly white crystalline solid, which needs only to be ground and packed into kegs to be made ready for the market. The unground arsenic is, as stated, all in the *crystalline* condition, the temperature of the chambers being too low to permit the formation of the glassy variety.

The German arsenic occurs in commerce, in masses, with a vitreous fracture, and of a milk-white color externally, but, internally, often perfectly transparent. As first sublimed, the whole mass is transparent; but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. This change has not been well explained, but probably depends upon the absorption of moisture, causing a gradual passage of the acid from the amorphous to the crystalline state.

Description and Physical Properties.—"A white powder, or irregular masses of two varieties, one amorphous, transparent, and colorless, like glass; the other, crystalline, opaque and white, resembling porcelain. Frequently the same piece has an opaque, white, outer crust enclosing the glassy variety. Contact with moist air gradually changes the glassy into the white, opaque variety. All varieties are odorless. *Caution.—Arsenic Trioxide is extremely poisonous.*

"Arsenic Trioxide is slowly soluble in water, the amorphous or glassy variety being somewhat more soluble than the crystalline. It is slightly soluble in alcohol and in ether, and freely soluble in glycerin. It is dissolved by hydrochloric acid and by solutions of alkali hydroxides and carbonates. An aqueous solution of Arsenic Trioxide is faintly acid to litmus paper. When slowly heated in a dry test tube of hard glass, Arsenic Trioxide yields a sublimate of minute crystals. When heated rapidly to about 200° C., the amorphous variety fuses, then sublimes, while the crystalline variety sublimes without fusing. When Arsenic Trioxide is covered with charcoal in an ignition tube and strongly heated, it is reduced to metallic arsenic which is deposited on the cooler portion of the tube as a mirror, having a metallic luster. This mirror is rapidly soluble in solution of chlorinated lime or chlorinated soda. Hydrogen sulphide T.S. colors an aqueous solution of Arsenic Trioxide (1 in 100) yellow. Upon the addition of a few drops of hydrochloric acid to the colored solution, a lemon-yellow precipitate of arsenic trisulphide is produced.

"Not more than 0.1 per cent. of residue remains upon the ignition of 1 Gm. of Arsenic Trioxide. Dissolve 1 Gm. of Arsenic Trioxide in 10 cc. of ammonia T.S. with the aid of gentle heat: a clear, colorless solution results. Dissolve about 0.2 Gm. of Arsenic Trioxide in 50 cc. of distilled water with the aid of 2 cc. of hydrochloric acid and completely precipitate by hydrogen sulphide. Allow the precipitate to subside, and pour off the clear liquid: the precipitate dissolves completely upon the addition of an excess of ammonium carbonate T.S. (*antimony, tin, or cadmium*).

"**Assay.**—Dissolve about 0.2 Gm. of Arsenic Trioxide previously dried to constant weight at 100° C., and accurately weighed, in 20 cc. of boiling distilled water, and gradually add sodium hydroxide T.S. until complete solution results. Neutralize this solution with diluted sulphuric acid, using phenolphthalein T.S. as indicator, cool, dissolve in it 2 Gm. of sodium bicarbonate, and titrate the mixture with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3." *U. S.*

"A heavy white powder, or broken white lumps which have a vitreous fracture and usually appear stratified. Very slowly soluble in 65 parts of *water*. Slowly heated in a test-tube it yields a sublimate of minute, brilliant, transparent, octahedral crystals. Its aqueous solution, which is odorless, tasteless, and faintly acid to *litmus*, gives with *solution of silver ammonio-nitrate*, a canary-yellow precipitate readily dissolved by *solution of ammonia* and by *nitric acid*. Sprinkled on ignited charcoal, it emits an alliaceous odor. Entirely volatilised by heat. 0.1 gramme, dissolved in boiling *water* with the aid of a little *solution of sodium hydroxide*, the cooled solution being slightly acidified with *hydrochloric acid* and then made alkaline with excess of *sodium bicarbonate*, decolorises not less than 20.1 millilitres of *N/10 solution of iodine*. Dissolves completely in *solution of ammonia*, and the resulting liquid, when diluted with an equal volume of *water* and acidified with *hydrochloric acid*, is not yellow (absence of arsenious sulphide)." *Br.*

The English make of arsenic is always powdered, and, under a lens, is seen to consist of small crystals perfect in form, or of small fragments of larger crystals. As it occurs in commerce for medicinal use, it is often in the form of a white powder, almost as fine as flour. It has no odor, even in vapor; but when thrown on ignited charcoal it emits a garlicky odor, in consequence of its deoxidation, and the volatilization of the reduced metal. Its point of sublimation, according to Berzelius, is at an incipient red heat; but, according to Mitchell and Durand, it is lower than that of metallic arsenic, being only 218° C. In the British Pharmacopœia, 1898, it is said to be volatilized at a temperature not exceeding 204.4° C. When slowly sublimed it condenses in regular octahedral crystals of a sparkling luster. It may also be obtained crystallized in fine octahedral crystals by the slow-cooling of a solution of the oxide in boiling diluted hydrochloric acid.

Uses.—The official preparations of arsenic are all of them, when in sufficient concentration, violent irritants or escharotics. Taken internally in sufficient dose they are exceedingly poisonous to both man and the lower animals.

Although in large doses arsenous oxide depresses the central nervous system and also the vasomotor center, these effects have no connection with its therapeutic uses. The properties for which it is employed in practical medicine, so far as they are at all explicable, may be ascribed to its influence on the nutritive processes and the blood making organs, or to its toxic action on certain lower forms of life. Arsenic in sufficient strength is capable of destroying the vitality of all forms of living matter but appears to be especially poisonous to certain pathogenic micro-organisms. While because of its general protoplasmic toxicity it has a certain degree of power as an antibacterial, it is too poisonous to man for use as a medical germicide.

The most important physiological action of arsenic is its power of inhibiting chemical actively of the bodily cells; in other words, it lessens nitrogenous metabolism. Because of the diminished metabolism there is a tendency for the body to take on weight. This effect is especially marked in growing animals. Gies found that newly born rabbits after four weeks of arsenical treatment averaged 30 per cent. heavier than normal and that the bones were longer and thicker, and there was a proportional increase in the muscular tissue. Van den Eckhout (*C. R. S. B.*, 1921, lxxxv, 740) although he failed to obtain evidence of increased growth found that the bones become denser and stronger. Especially marked in the human being have been the nutritive changes in the skin. The mode of action of arsenic in dermatological conditions is not well understood, but in cases of chronic arsenic poisoning one of the most remarkable symptoms has been the overgrowth of the horny layer and appendages, such as the nails. After small doses of arsenic there has been demonstrated, in the lower animals, hyperemia of the bone marrow and an increase in the number of white blood corpuscles. We have, however, no knowledge of any physiological action which would explain its beneficial influence in *anemia;* the proof of its value in this condition rests entirely on clinical evidence.

The therapeutic uses of arsenic may be divided into six categories: (1) to stimulate nutrition, (2) for its effect on the blood, (3) in the treatment of certain skin diseases, (4) for its effect upon the bronchial mucous membrane, (5) for the destruction of certain pathogenic micro-organisms, and (6) as a local remedy.

In chronic wasting diseases, as in *tuberculosis* or in certain types of *neurasthenia* with malnutrition, arsenic is one of the most powerful drugs that we possess. It is one of the very few substances which really deserves the name of a general tonic since it increases both the weight and strength of the patient. It is perhaps due to its effect on nutrition that it owes its value in certain obscure nervous diseases, especially *chorea* and *migraine.* It is also sometimes a powerful remedy in various chronic types of *arthritis.*

In *chlorosis,* as shown by Seiler (*D. M. W.,* 1911, xxxvii, 1340), arsenic by itself has little if any beneficial power, but in some way greatly enhances the action of iron. In other types of *anemia,* in which iron is of little value, especially the so-called *pernicious anemia,* arsenic often produces marked amelioration. In the various types of *leukemia* it frequently produces marked temporary improvement but rarely permanent cures. It is possible that its value in these latter dyscrasias of the blood, as well as in *malarial anemia,* is due to an action upon some causative parasite. In skin diseases its use should be avoided in the acute inflammatory forms, reserving it for the more sluggish lesions, such as certain types of chronic *eczema* or *psoriasis.*

While the inorganic forms of arsenic are highly toxic to many of the hematozoa they are usually less successful in the treatment of parasitic infections of the blood than the organic forms, because the latter can be given in so much larger doses without danger to the human host. (See *Atoxyl* and *Arsphenamine.*) To what action arsenic owes its value in pulmonary diseases is entirely unknown, but there is strong clinical evidence that in chronic *bronchitis,* especially of the aged, and in *asthma* it is often of much service.

Locally arsenic is a valuable caustic for the destruction of *malignant growths.* While a universal poison, the cells of unhealthy tissue are more readily affected by it than normal structure and it is therefore used widely for the destruction of *cancers,* especially of the skin. It is an ingredient of nearly all the proprietary and semi-proprietary cancer pastes. *Plunket's caustic* consists of *Ranunculus acris* and *Ranunculus flammula,* each one ounce, bruised and mixed with sixty grains of arsenic trioxide and one hundred grains of sulphur; beaten into a paste and dried in the sun. *Arsenical paste of Frére Côme* was made by mixing water with a powder consisting of ten grains of arsenic trioxide, forty grains of red mercuric sulphide, and ten grains of powdered animal charcoal.

Febure's remedy for cancer consisted of ten grains of arsenic trioxide, dissolved in a pint of distilled water, to which were added an ounce of extract of conium, three fluidounces of solution of lead subacetate, and a fluidrachm of tincture of opium. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenic trioxide two grains, rhubarb half an ounce, syrup of chicory q. s., distilled water sufficient to make a pint. Of this mixture, a tablespoonful, containing about the sixteenth of a grain of the oxide, was given every night and morning. The dose was gradually increased to six tablespoonfuls a day.

The *Asiatic pills,* so called, consist of arsenic trioxide and black pepper, in the proportion of 1 part of the former to 80 parts of the latter. A preparation much used on the continent of Europe is *Boudin's solution,* which is simply an aqueous solution of arsenic trioxide with the addition of wine, and is made by boiling one gramme (15.4 grains) of the oxide with one liter (2.1 pints) of distilled water till entirely dissolved, then cooling, filtering, adding enough distilled water to supply the loss, and finally mixing with one liter of white wine. Of this solution a fluidounce contains about one-quarter of a grain of arsenic trioxide.

In certain portions of Styria the peasants are in the habit of taking routinely considerable quantities of a native arsenical earth. The quantities of arsenic ingested by these so-called *arsenic eaters* is extraordinarily large; it is well established that they will imbibe amounts of more than half a grain at a dose. It has been commonly believed that lack of toxic action was due to tolerance formed through the long-continued use of the metal. Recent investigators, however, especially Schwartz (*J. P. Ex. T.,* 1922, xx, p. 181), have thrown considerable doubt on this theory and explain the lack of toxic symptoms on the ground of non-absorbability of solid arsenic. Schwartz has found that the pure arsenous oxide varies enormously in its toxicity according to the fineness of its pulverization. Cloetta (*A. E. P. P.,* 1906, liv) showed that the tolerance which can be induced in dogs is due to an irritation of the intestinal tract which impedes absorption, and Sollmann (*J. P. Ex. T.,* 1921, xviii, p. 43) was unable to produce in rats any increased resistance to arsenic. While the question can not yet be considered as fully settled, the present evidence throws grave doubt on the possibility of an acquired immunity towards this poison.

Toxicology.—Arsenic is one of the most commonly used poisons for criminal purposes. The symptoms, which generally do not appear for a period of from one-half to one hour after the ingestion of the poison, are somewhat varied in different cases. The most frequent symptoms are pain in the epigastrium, vomiting, the vomitus being occasionally bloody, more commonly not, profuse serous purging, great thirst, rapid, weak pulse, prostration and weakness, and restlessness, sometimes with delirium and convulsions. Any or all of these symptoms, however, may be lacking, death occasionally taking place with no prodromal symptoms except heart failure or stupor. Death usually occurs in the fatal cases after about twenty-four hours but may occur within an hour, or may be delayed for more than a week. At post-mortem examination there will be found evidence of inflammation of the alimentary canal and of the kidney and frequently fatty degeneration in various of the internal organs.

There can be no doubt that, when applied to any ulcerated surface, arsenic may be absorbed with fatal result; death has indeed occurred in a number of cases from the use of arsenic as an escharotic to tumors, cancerous ulcers, etc. As indicated by Blackader, absorption is less likely to follow the use of large than of small quantities, the larger amount probably killing the part to which it is applied, and thereby preventing absorption. If this dangerous caustic be used at all, it should be in accordance with these facts. Harles's observations also seem to show that when the surface is that of a chronic ulcer, either simple or malignant, absorption is less prone to occur than from a fresh wound.

The diagnosis of acute arsenical poisoning is sometimes impossible without chemical examination. For the methods of detecting arsenic in the human body, see *U. S. D.*, 19th edition, p. 202. It should be remembered that even after the post-mortem injection of arsenic, as in the use of embalming fluids, the poison may be diffused throughout the entire body.

In the *treatment* of poisoning by arsenic, it is of the utmost importance to prevent the absorption of the drug, because after the poison has once entered the system, there is probably nothing that can be done to mollify its baneful effects. The most important method of preventing absorption is the mechanical evacuation of the stomach—unless nature has already done so by vomiting—either by use of the stomach tube or a promptly acting emetic such as zinc sulphate. It is to be remembered that, especially if the arsenic has been taken in solid form, the poison may remain in the stomach for long periods, and therefore even if the patient is not seen immediately after the ingestion of the poison, the cleaning of the stomach is still advisable. The removal of the gastric contents should be folowed by evacuation of the intestines by a saline purgative such as magnesium sulphate. Chemical antidotes may be of adjuvant service and useful to prevent absorption temporarily when emetics are not immediately available, but they ought never be allowed to exclude the mechanical washing of the stomach. Among the chemical antidotes we believe the most useful is ferric hydroxide or preferably ferric hydroxide with magnesium oxide, in the moist or pulpy state. The official *Ferri Oxidum Hydratum cum Magnesii Oxido* is the best form and may be given in doses of one-half to one tumblerful. Its efficacy is, of course, greater the sooner it is administered after the ingestion of the poison; but even after delay its use will prove advantageous, so long as any portion of the poison still remains in the stomach. Ferric hydroxide acts by producing with the poison, by a transfer of oxygen from the oxide to the acid, an insoluble, and therefore inert, ferrous arsenate: $4Fe(OH)_3 + As_2O_3 = Fe_3(AsO_4)_2 + 5H_2O + Fe(OH)_2$.

It should always be freshly prepared immediately before use. (See *Ferri Hydroxidum cum Magnesii Oxido.*) Dialyzed iron and saccharated oxide of iron have been suggested as an antidote but are less efficient. The light magnesium oxide has also shown itself possessed of antidotal properties, and the U. S. has authorized the use of magnesia to precipitate the ferrous hydroxide. For the full precipitation of arsenic trioxide eighteen parts of weight of the anhydrous magnesia are required.

If the official antidote be not directly at hand, a substitute can be extemporized by adding to a solution of any soluble ferric salt some form of alkaline hydroxide.

As the result of studies on dogs, McGuigan, Atkinson and Brough (*J. A. Ph. A.*, 1923, xii, 327) have called in question the antidotal value of ferric hydroxide. Although the interpretation of their experimental results has been criticized (see Wood, *J. A. Ph. A.*, xii, 482) they have at least emphasized the importance of the evacuation of the stomach in the treatment of poisoning by arsenic.

The subsequent treatment consists in the administration of mucilaginous drinks, and the treatment of symptoms as they arise. Convalescence is generally long and distressing; usually dyspeptic symptoms mark the presence of gastro-intestinal inflammation or even ulceration, while not rarely violent neuralgic pains, with loss of power, wasting of the muscle, and other trophic changes, show that a peripheral neuritis has been produced.

Chronic arsenical poisoning has occurred either as a result of the inhalation or the swallowing of the poison. Wall paper which is colored with arsenical dyes has been shown to be capable of giving off a fine poisonous dust. Chronic arsenic poisoning has also occurred from various foodstuffs colored with arsenic—containing dyes, and a large epidemic which occurred in Manchester in the year 1900 was traced to glucose used in the manufacture of beer, originating in this case in the arsenic contaminating sulphuric acid used in making the glucose. The symptoms are so protean as to defy detailed description. The most important are *peripheral neuritis,* inflammation or overgrowth of the skin and dermal appendages, and irritation of the alimentary canal; when the poison has been inhaled to these are often added the signs of laryngitis and bronchitis.

When preparations of arsenic are given for their tonic effect only, they should be used in doses so small as not to cause any general symptoms; but when a specific action, as in *chorea,* is desired, it is proper to begin with small doses and rapidly increase them until the limit of tolerance is reached. Not rarely, such doses produce gastro-intestinal irritation, especially pain and diarrhea. To avoid this as much as possible, the remedy should be given after meals. When either gastro-intestinal irritation, puffiness under the eyes, or other of the peculiar effects of arsenic are caused, the drug should be, at least temporarily, withdrawn. The specific symptoms of *arsenicalism* are a general disposition to edema, especially of the face and eyelids, a feeling of stiffness in these parts, itching of the skin, tenderness of the mouth, loss of appetite, and uneasiness and sickness of the stomach, usually with diarrhea. The peculiar swelling produced is called *œdema arsenicalis.* When used continuously over long period of time even in doses too small to cause the customary symptoms of arsenicalism the drug may give rise to alterations in the skin. The most important of these are peculiar dryness and a tendency to the overgrowth of the keratin as shown by the formation of warts. These skin lesions may be accompanied with evidence of peripheral neuritis. (See under *Chronic arsenical poisoning.*) In some instances the internal use of arsenic causes a rash not unlike that of measles, and, as in that affection, attended with catarrhal symptoms. Sometimes salivation is produced, and occasionally the hair and nails fall off.

Dose, of arsenic trioxide, one-fortieth to one-twentieth of a grain (0.0016–0.003 Gm.).

"*Note.—The fine degree of subdivision of the powdered form of this arsenic trioxide renders it more soluble and therefore more effective than the powder previously official. This should be borne in mind in adjusting the dosage.*" *U. S.*

ARSENUM.

ARSENIC

As = 74.96.

Arsenicum, *U. S.* 1870; Arsenium; Arsenic, *Fr.;* Arsen; Arsenik, *G.;* Arsenico, *It.;* *Sp.*

For a method of preparing metallic arsenium from the oxide see *U. S. D.,* 20th ed., p. 196.

Arsenium is a brittle, crystalline metal, of a steel-gray color, and possessing much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and blackish. Its texture is granular, and sometimes a little scaly. Rubbed on the hands, it communicates a peculiar odor, but it is devoid of taste. Its sp. gr. is about 5.73 (5.88). When heated to about 180° C. it sublimes, giving rise to white vapors having a garlicky odor. The statement that arsenic on being heated sufficiently, passes at once into the state of vapor without fusing was disproved by experiments of Dunnington and Odger, made under direction of Mallet. They succeeded in fusing arsenic without great difficulty. An amorphous modification results from the decomposition of hydrogen arsenide by heat, the arsenic appearing as a dark brown deposit. There is also a yellow modification which is formed when arsenic vapor is strongly cooled; it resembles yellow phosphorus, as it is soluble in carbon disulphide and oxidizes in the air with luminosity.

The atomic weight of arsenium is 74.96. It forms two combinations with oxygen, arsenous and arsenic oxides, As_2O_3 and As_2O_5 respectively, to each of which the corresponding acid is known, and three with sulphur, namely, the disulphide, or realgar, As_2S_2; the trisulphide, or orpiment, As_2S_3, corresponding in composition to arsenous oxide; and the pentasulphide, As_2S_5, corresponding to arsenic oxide. (See *Arseni Trioxidum;* also *Realgar* and *Orpiment* in Part II of this work.) *Arsenic oxide* is obtained by distilling off a mixture of twelve parts of nitric and one of hydrochloric acid from four parts of arsenic trioxide, until the whole acquires the consistence of a thin syrup. The liquid is then poured into a porcelain dish, and evaporated at a moderate heat. Suddenly the arsenic oxide concretes into an opaque white mass, which should be transferred, while warm, to a well-stoppered bottle. Arsenic oxide is white, solid, deliquescent, and soluble in six parts of cold and two of boiling water. It forms several acids, corresponding to the several varieties of phosphoric acid, to which it bears a close analogy. With silver nitrate it gives a brick-red precipitate of silver arsenate.

The world's supply of arsenic and arsenic compounds at the present time is obtained chiefly from Germany, Spain, England and Canada, although in Montana and Washington considerable quantities of arsenic are being produced as a by-product in the smelting of copper ores.

The detection of arsenic in toxicological procedures is accomplished by means of the method known as Marsh's test for arsenic which depends upon the liberation of H_3As (*arsene*) and its subsequent reduction to metallic arsenic in a hard glass tube or upon a cold porcelain surface. The Marsh test has largely been replaced by the modified Gutzeit test which requires much less elaborate apparatus and may be made accurately quantitative. This is the test which is described in the U. S. P. (See *Arsenic Test*, Part III.)

Arsenic is much diffused. Besides being present in a great many minerals, it has been detected, in minute proportion, in certain soils and mineral waters; in the ashes of various plants by Stein; also in various mineral coals. Recently it has been found in minute quantities in many plants and even in the tissues of the human body.

ARSPHENAMINA

ARSPHENAMINE Arsphen. [Diaminodihydroxyarsenobenzene Hydrochloride]

"Arsphenamine [$HCl.NH_2.OH.C_6H_3As:As\text{-}C_6H_3.OH.NH_2HCl.2H_2O$] contains not less than 30 per cent. of arsenic (As), and complies with the requirements of the United States Public Health Service." *U. S.*

Salvarsan, 606, Arsaminol, Arsenobenzol, Diarsenobenzol, Arsenobillion, Arsen-phenol-amine Hydrochloride, Kharsivan, Dioxydiamidoarsenobenzol, 3.3-diamino-4.4-dihydroxy-arsenobenzene.

Arsphenamine is prepared commercially by reduction of 3-nitro-4-hydroxy-phenyl-arsenic acid, generally with sodium hydrosulphite. There are a number of modifications of the method of manufacture, the modifications usually having to do with the method of obtaining the 3-nitro-4-hydroxy-phenyl-arsenic acid.

According to Raiziss and Proskonriakoff (*Arch. of Derm. and Syph.*, 1920, ii, p. 280), the theoretical percentage of arsenic in arsphenamine is 31.6 and of nitrogen 5.89; but neither the percentage of arsenic, nor of nitrogen, nor the ratio between the two, nor the amount of oxygen absorbed by the preparation affords any criterion of the toxicity of a sample. In the twelve samples examined by them the percentage of arsenic varied from 29.3 to 31.8, and of nitrogen from 5.40 to 5.95.

H. Cousin (*J. P. C.*, 1920, xxii, 390) points out that the toxic compound which develops in arsenobenzol is an oxidation product, *amino-oxyphenyl arsenous-oxide*. This compound was stated by Ehrlich to be twenty times more toxic than fresh arsphenamine, and an assay has been suggested which will determine the preparation of water soluble arsenous oxide, which should not be more than 0.8 per cent. Administration of arsphenamine requires very careful manipulation on the part of the pharmacist or physician who prepares it for hypodermic use.

As arsphenamine appears upon the market it is a hydrochloride. Upon the addition of a very small amount of sodium hydroxide, the base itself is liberated in the form of an insoluble yellow precipitate which is not suitable for intravenous administration. The addition of a slightly larger amount of sodium hydroxide solution produces the mono-sodium salt of arsphenamine which, while entirely soluble, is still not a proper form for intravenous administration. The only proper form is the disodium salt which is produced by the addition of the amount of sodium hydroxide necessary to produce this definite compound. The United States Public Health Service has issued a circular concerning the outline and rate of administration of arsphenamine solution in which the subject is discussed from the standpoint of errors which may occur in the preparation and administration of this remedy.

Arsphenamine may vary considerably in toxicity in consequence of the presence of certain impurities derived during its manufacture. The presence of some inorganic arsenic, even when carefully made, as well as organic arsenic compounds having a greater toxicity than arsphenamine makes a biologic test imperative before the product may be placed upon the market. Sulphur compounds of arsenic are also stated to cause some of the toxic effects of certain specimens of arsphenamine. Christensen (*J. Am. C. S.*, 1921, xliii, 2202) states that the most important factor in the preparation of arsphenamine of low toxicity, is to use pure 3-amino-4-hydroxy-phenylarsonic acid as the starting point.

Arsphenamine may be conveniently identified by Gaebel's reaction in which it gives a positive diazo reaction with *alpha-naphthylamine* but no reaction with the *beta* compound.

It may be distinguished from neo-arsphenamine by adding picric acid T.S. Arsphenamine produces an immediate yellow precipitate, while neo-salvarsan produces only a slight opalescence even after long standing.

Kober (*J. P. Ex. T.*, 1925, xxv, p. 154) states that the commercial arsphenamines differ from the compound originally described by Ehrlich, in being soluble in methyl alcohol and that they are also therapeutically less efficient. He states that the reprecipitation of these commercial products by hydrochloric acid increases their potency and reduces their toxicity. He further asserts that manufacturers in their effort to produce arsphenamine or especially neo-arsphenamine of low toxicity are sacrificing curative power.

Description and Physical Properties.—"A light yellow powder. It is odorless or has a slight odor, and is hygroscopic. In the dry state or in solution it is oxidized by exposure to the air, becoming darker and more toxic. Arsphenamine is soluble in water, alcohol, and glycerin, but only very slightly soluble in chloroform and in ether.

"An aqueous solution of Arsphenamine (1 in 100) is acid to litmus paper (difference from *neoarsphenamine*). Add sodium hydroxide T.S., drop by drop, to an aqueous solution of Arsphenamine (1 in 100). A precipitate is formed (difference from *neoarsphenamine*), which readily dissolves in an excess of the sodium hydroxide. Sodium carbonate T.S. or solution of sodium bicarbonate also produces a precipitate, but this is insoluble in an excess of the reagent. An aqueous solution of Arsphenamine (1 in 100) is precipitated by mercuric potassium iodide T.S. (difference from *neoarsphenamine*). An aqueous solution of Arsphenamine (1 in 100) is unaffected by the addition of diluted hydrochloric acid, diluted nitric acid, or by acetic acid even after heating (difference from *neoarsphenamine*). With an excess of hydrochloric acid a precipitate is formed. Diluted sulphuric acid or solutions of alkali sulphates immediately produce a precipitate. The addition of 2 drops of freshly prepared ferric chloride T.S. to 5 cc. of an aqueous solution of Arsphenamine (1 in 1000) produces a brownish, violet tinted color, rapidly changing to deep red. Add 3 cc. of silver nitrate T.S. to 5 cc. of an aqueous solution of Arsphenamine (1 in 100). A red color is produced, but no precipitate is formed even after standing at ordinary room temperature for ten minutes (difference from *neoarsphenamine*). When a 6 cc. portion of silver nitrate T.S. is added to the same volume of solution, a precipitate is immediately formed which blackens on heating. On now adding 5 cc. of nitric acid, and again heating, the precipitate becomes white and dissolves in ammonia water. The solution resulting from the following assay yields with hydrogen sulphide a yellow precipitate, soluble in ammonium carbonate T.S.

"**Assay.**—Place about 0.2 Gm. of Arsphenamine, accurately weighed, in a glass-stoppered, 200 to 300 cc., flask. Add 1 Gm. of finely powdered potassium permanganate and 5 cc. of diluted sulphuric acid, and allow to stand for ten minutes, rotating the contents of the flask during this time to insure thorough mixing. Add 10 cc. of concentrated sulphuric acid in portions of about 2 cc., rotating the flask after each addition. When the reaction has ceased, add sufficient hydrogen dioxide T.S. to dissolve completely the brown precipitate (about 5 to 7 cc.). Toward the end of the reaction the hydrogen dioxide is to be added drop by drop to avoid any great excess. Dilute with 25 cc. of distilled water, and boil gently over an asbestos wire gauze for from fifteen to twenty minutes, or until the excess of hydrogen dioxide is expelled. Dilute with 50 cc. of distilled water, and add tenth-normal potassium permanganate until the liquid is faintly pink, then discharge the pink color by the addition of a drop of tenth-normal oxalic acid. Cool the solution, add 2.5 Gm. of potassium iodide, stopper the flask tightly, and allow it to stand in a cool, dark place for one hour. Then titrate the liberated iodine with tenth-normal sodium thiosulphate without the use of starch indicator. Make a blank test with the same quantities of the reagents, and correct the assay for the volume of tenth-normal sodium thiosulphate used in the blank. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003748 Gm. of As.

"Preserve in sealed containers of colorless glass, from which the air has been excluded either by the production of a vacuum or by displacement with a non-oxidizing gas." *U. S.*

Uses.—This compound was introduced into medicine in 1910 as the result of a long series of experiments by Ehrlich, undertaken with the idea of preparing a substance which should be non-toxic for higher animals, especially man, but poisonous to certain infective parasites.

Arsenic, when in the pentavalent state, is relatively non-poisonous to either unicellular or more highly developed micro-organisms. Therefore, while pentavalent arsenicals are not injurious to human beings, they are likewise not destructive to pathogenic micro-organisms. The destructive effect of arsenic upon infecting parasites—*i.e.*, its therapeutic activity—depends upon the decomposition of the molecule, probably by oxidation, with the liberation of the arsenic in a trivalent, or active, state. Unfortunately, the human tissues have this same power of oxidizing arsphenamine so that it is toxic to man as well as micro-organisms. Certain types of organisms, however, appear to decompose this compound more rapidly; to them it is, therefore, more poisonous than to their human host and for this reason can be used to destroy these parasites in the body. The only group of micro-organisms which have been definitely shown to be peculiarly susceptible to arsphenamine are the protozoa which are today grouped together under the genus *Spirochæta*. To this genus belong the germs giving rise to relapsing fever, syphilis, yaws, rat-bite fever, Vincent's angina, yellow fever, etc. By far the most important of this group of infections is *syphilis*.

Although arsphenamine has failed to realize the hopes of its inventor, who had dreams of a compound so innocuous to man that a single dose might be given large enough to destroy all the parasites in the body and thus cure at once the infection, there can be no doubt of its value in syphilitic disease. It is probable that if used during the primary stage of the infection a considerable proportion of cases can be rapidly and permanently cured. In the secondary stage its effects are less certain and most modern syphilographers not only recommend repeated doses of arsphenamine but also the use of mercury as a succedaneum. One great benefit from arsphenamine in this stage is that it causes a rapid disappearance of the gross lesions of the infection thereby not only lessening the liability of permanent sequela of the diseased person, but also rendering him less liable to spread the infection. If the patient is not seen until the establishment of the tertiary lesions, while arsphenamine should usually be employed in the hope of preventing further progress of the disease, it must be remembered that it cannot exercise any beneficial action on the sclerotic degenerations which have been the result of the syphilitic fires and, therefore, it may fail to produce any great amelioration of symptoms.

Arsphenamine has been used in an experimental way, at least, in practically all protozoal infections and even in a number of bacterial diseases. An excellent résumé of its effects in non-syphilitic diseases, with numerous references to the literature, has been made by Reasoner and Nichols (*J. A. M. A.*, 1920, lxxv, p. 645). In *relapsing fever* its effects are very striking; according to Manson and Thornton (*Journal of the Royal Army Medical Corps,* August, 1919), the most satisfactory results are obtained from it if it is given during the febrile period. A number of authors have reported very favorable results in *Vincent's angina;* Reckford (*J. A. M. A.*, 1920) recommends the local application of a 10 per cent. solution of arsphenamine, in glycerin, directly to the lesions, by means of a cotton swab, twice daily. This solution should be well rubbed in. If the lesions have become very extensive it may be advisable to also give the drug intravenously. In the tropical disease known as *yaws* or *frambesia,* arsphenamine seems to realize the ideal of Ehrlich of a *therapia sterilisans magna,* an immediate cure from a single dose. Noguchi (*J. Ex. M.*, 1919, xxix, and xxx) has shown that *yellow fever* is due to an organism belonging to the group of spirochetes. While some authors have reported favorably on the use of arsphenamine in this infection, its value is not firmly established. All of the foregoing are spirochete infections, but the use of arsphenamine has not been limited to this group of diseases. Allied to the spirochetes are the trypanosomes, one of which gives rise to the almost universally fatal *African sleeping sickness,* and others to various diseases of lower animals. While laboratory trypanosomiasis can be almost absolutely controlled by arsphenamine, the results of its use in human infection have been far from satisfactory. In many cases it has exercised an apparently beneficial action but its effects do not seem to be superior to other arsenicals, such as atoxyl. In *malarial fevers* it is apparently of some value in quartan and tertian fevers, which have been proved refractory to quinine, but here again it is very questionable whether it is superior to older arsenicals. Carr and Chandler (*J. A. M. A.*, 1920, lxxiv, May 22) have reported beneficial effects in amebic *dysentery* and the allied condition known as *trench-diarrhea* or *giardiasis.* Allison (*J. M. R.*, 1918, xxviii, p. 55) states that arsphenamine has a powerful germicidal effect on streptococci and has achieved favorable results from its use in experimental *septicemia.* Evidence of its clinical use in this disease is as yet lacking. Perrin (*Paris Med.*, Dec. 10, 1921) and Molnar (*W. K. W.*, 1921, xxxiv, p. 255) both report good results from it in the treatment of *gangrene of the lungs.*

Toxic Effects.—Arsphenamine has produced, in a large number of cases, unpleasant and even alarming symptoms and in a few, fatal results. It is difficult to determine accurately the number of deaths attributed to the drug. Guy (*J. A. M. A.,* 1919, lxxiii, p. 901) in 25,000 injections, done under careful technic, had two deaths. Corlett (*J. A. M. A.*, 1913, lxi,) from a careful review of the literature during the first three years after the introduction of this remedy, estimated the mortality from its use as one death in 18,000 injections. The toxic manifestations may be divided into five groups: (1) those due to acute poisonous effects of arsphenamine itself; (2) those resembling arsenic poisoning and probably due to too rapid oxidation of the compound in the body; (3) those due to idiosyncrasies, either inherent or acquired, of the patient; (4) those due to impurities in commercial samples of the drug; (5) those due to errors of technique of its administration.

Smith (*J. P. Ex. T.*, 1920, xv, p. 279) has shown that when rapidly injected into a vein, arsphenamine causes a violent contraction of the pulmonary arteries with an accompanying rise in the pulmonary and fall in the general blood pressure. If the dose has been large enough, this is followed by dilation of the right heart and death from circulatory collapse. These effects are produced only when the drug is injected too rapidly or in too concentrated solution. Accidents of this type from the clinical use of the drug are comparatively rare.

Two types of toxic cases have been reported which suggest arsenical poisoning; these have shown either neuritis, especially of the optic nerve, or signs of degeneration of the liver. Lynch and Hoge (*J. A. M. A.*, 1919, lxxiii, p. 1687) reported three cases of toxic jaundice, one of which ended fatally, the symptoms of which suggested acute yellow atrophy of the liver. Several similar cases have been reported by Stümpke (*Med. Klin.*, 1922, xviii, 295) and others. It has been suggested that both these neuritic and hepatitic accidents are the result of the syphilis rather than of the arsphenamine, but it seems impossible to explain all of them on that basis. They are, however, comparatively infrequent. The most common type of unpleasant reaction is characterized by chill followed with fever, associated with nausea and sometimes severe vomiting, the whole lasting from two hours to two days and often followed by herpetic eruptions. Another type of reaction, which is commonly called "nitritoid crisis" consists of sensation of choking, redness of the face and cardio-respiratory embarrassment. These groups of reactions have been variously attributed to imperfect technic, impurities in the drug, improperly distilled water, etc. The observations of Busman (*J. A. M. A.*, 1921, lxxvi, p. 1302) indicate very strongly, however, that in many instances at least they are to be classed among the anaphylactoid reactions and are more likely to occur after repeated than after the first injection. Milian (*Paris Med.*, Feb. 2, 1918) has found epinephrine of great value both as a preventive and curative of the nitritoid crisis.

Administration.—Arsphenamine has been employed by intravenous, intramuscular and intrarectal injection. Most authorities, however, give preference to the intravenous route. The following important points in the technic of this injection must be carefully observed: The ampules of the drug should be floated in alcohol for the purpose of detecting any flaw in the containers. The contents are then dissolved in sterile, *freshly distilled* water and a 15 per cent. solution of sodium hydroxide added drop by drop until the precipitate which at first forms, is redissolved and one or two drops of the soda solution are added in excess. This solution is then diluted with further portions of the freshly distilled water. The concentration of solution which is to be recommended is a matter of considerable difference of opinion. In general, the tendency seems to be, for intravenous injection, to employ the drug in strengths of about 0.5 per cent. The solution, which should be at body temperature, must be injected very slowly.

Dose, of asphenamine, is from three to nine grains (0.2–0.6 Gm.) which may be cautiously increased, usually given at intervals of a week.

ASAFŒTIDA. U. S. (Br.)

ASAFETIDA Asafœt. [Gum Asafetida]

"Asafetida is gum-resin obtained by incising the living rhizomes and roots of *Ferula Asafœtida* Linné and *Ferula fœtida* Regel and of other species of *Ferula* (Fam. *Umbelliferæ*). Asafetida yields not less than 50 per cent. of alcohol-soluble extractive and not more than 15 per cent. of acid insoluble ash." *U. S.* "Asafetida is an oleo-gum-resin obtained by incision from the root of Ferula fœtida, *Regel,* and probably other species of Ferula." *Br.*

Asafetida, *Br.*; Stercus Diaboli, Cibus Deorum; Gummiresina Asafœtida; Asa fœtida, Asse-fétide, Assafœtida, *Fr.*; Asa fœtida, *P. G.*; Asant, Stinkasant, Teufelsdreck, *G.*; Assa fetida, *It.*; Asafetida, *Sp.*; Ungoozeh, *Pers.*; Hilteet, *Arab.*; Hing, *India;* Angusa-kema, *Afgh.*

Ferula Asafœtida was first described from actual observation by H. Falconer, who found it near Kashmir, and it has long been successfully cultivated in the Edinburgh Botanical Gardens. It is distinguished from allied plants by the greater height of the stem (6 to 10 feet), and by the numerous stem leaves furnished with wide sheathing petioles. The flowers are pale yellow, and the oval fruit thin, flat, foliaceous, and reddish brown, with pronounced vittæ. It yields a milky juice having a powerful odor of asafetida.

Ferula fœtida is a coarse umbelliferous plant, growing from five to seven feet high, with a large fleshy root, the crown of which is covered with coarse bristly fibers, and gives origin to large bipinnate radical leaves and a nearly naked stem which has only a few bipinnate leaves without wide sheathing petioles, and ends at the top in very numerous umbels. The flat-winged fruits have the vittæ almost obsolete. This plant was first discovered in the sandy desert near the sea of Aral, by Lehmann, in 1844. Bunge found it in Persia about twenty years later. It would seem to be native all through Afghanistan.

It is possible that asafetida is obtained from other species of *Ferula,* yet the bulk of the drug probably comes from the official plants. Among the other plants yielding asafetida is *Ferula Narthex* Boiss. While this is disputed by Aitchison yet it appears that it is the source of the gum-resin obtained from certain portions of Afghanistan. Tschirch describes this plant with illustrations in *S. W. P.,* 1910, p. 289. E. M. Holmes's discussion of the asafetida plants (*P. J.,* ser. iii, xix, 1888–1889) still remains one of our chief sources of information on the subject. (See also article on the sources of the fetid gum-resins by James Small, *P. J.,* 1913, vol. xc, p. 287.) *Ferula Jæschkeana* Vatke, which has been believed to be the source of asafetida, according to E. M. Holmes, has, at least in its dried state, not the slightest odor of asafetida, and yields a strongly celery-scented juice. (*P. J.,* 1894, xxv.)

The asafetida plants are indigenous to Western Afghanistan and Eastern Persia. In 1687 the collection of asafetida was witnessed by Kaempfer, whose description of the method is very similar to that given by J. E. T. Aitchison in 1884. According to Aitchison, the high plains of Afghanistan, two to four thousand feet above the sea, are arid and bare in winter, but in the early summer are covered with a thick growth of *Ferula fœtida, Dorema ammoniacum,* and *Ferula galbaniflua.* The great cabbage-like heads of the asafetida plant, representing the primary stage of the flower heads covered over by the stipules of its leaves, are eaten raw by the natives as a sort of green. In June the asafetida is obtained. The root-stock is first laid bare to the depth of a couple of inches, those plants only which have not reached their flower-bearing stage being selected. A slice is then taken from the top of the root-stock, which is immediately covered with twigs and clay, forming a sort of dome, with an opening towards the north, so that the sun cannot get at the exposed root. About five or six weeks later, a thick, gummy, not milky, reddish substance found upon the exposed surface of the root in more or less irregular lumps is scraped off with a piece of iron hoop or removed with a slice of the root and at once placed in a leather bag. The product of many plants is mixed and permitted to harden in the sun. Most of the drug is now gathered in Eastern Persia and Western Afghanistan. It is conveyed to Herat and Kandahar from whence it enters commerce. The present supply of this drug to America comes from London. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety pounds, the latter from two hundred to four hundred pounds. Asafetida is sometimes also imported in casks.

The fruit of the asafetida is said to be sent to India, where it is highly esteemed as a medicine.

Properties.—As usually found in commerce, asafetida is in irregular masses, soft when not long exposed, of a yellowish or reddish-brown color externally, exhibiting when broken an irregular, whitish, somewhat shining surface, which soon becomes red on exposure, and ultimately passes into a dull yellowish-brown. This change of color is characteristic of asafetida, and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as if composed of distinct portions agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the tears are separate, though rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, sometimes larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odor, which, however, is weaker than that of the masses.

The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its odor and taste, particularly the former. Asafetida softens by heat without melting, and is difficult of pulverization. Its sp. gr. is 1.327. (Berzelius.) It is inflammable, burning with a clear, lively flame.

Description and Physical Properties.—"A soft mass, sometimes almost semi-liquid, or irregular, more or less pliable masses composed of agglutinated tears imbedded in a yellowish-brown or dark brown matrix, or loose ovoid tears, from 1 to 4 cm. in diameter, the surface sometimes containing streaks of violet, yellowish-red or brownish-red and with a few vegetable fragments; becoming hard and occasionally brittle on drying; surface of the freshly fractured tears milky-white and opaque, changing gradually on exposure to air or light to a pinkish or reddish-purple or even reddish-brown; on moistening with water the tears become milky-white; odor persistent, alliaceous; taste bitter alliaceous and acrid.

"Asafetida, triturated with water, yields a milk-white emulsion, which becomes yellowish on the addition of alkalies. A reddish-brown solution is formed when a fragment of Asafetida is heated with sulphuric acid. Greatly dilute this solution with water, filter, and render alkaline: the solution acquires a blue fluorescence. A few drops of phloroglucinol T.S. and of hydrochloric acid added to 10 cc. of the alcoholic filtrate obtained in the assay, produces a cherry-red color.

"A few drops of ferric chloride T.S., added to 5 cc. of the alcoholic filtrate, obtained in the assay, produces an olive-green color (*most foreign resins*). Hydrochloric acid, added to 10 cc. of the alcoholic filtrate from the assay until a faint turbidity results, produces a bluish-green color which fades on standing (*galbanum*). Asafetida does not show the presence of rosin, page 457. Mix 2 cc. of an emulsion, prepared as directed under *Emulsum Asafœtidæ,* with 5 cc. of water and add 5 cc. of sodium hypobromite T.S. to form a separate layer: a red color is not produced (*ammoniac*).

"**Assay.**—Place about 10 Gm. of Asafetida in a tared, 250 cc. Erlenmeyer flask, weigh accurately, add 100 cc. of alcohol, and having connected the flask with an upright condenser, boil the mixture in the flask during one hour or until the drug is completely disintegrated. Filter and wash the flask and filter with several small portions of boiling alcohol until the washings no longer produce a cloudiness when dropped into water. Collect the mixed alcoholic solutions, using an aliquot part (50 per cent.) for the completion of the assay, and reserve the remainder for the tests given above. Evaporate the aliquot part in a suitable tared container and dry to constant weight. The anhydrous alcohol-soluble extractive of the aliquot portion equals not less than 25 per cent. of the weight of Asafetida taken." *U. S.*

"Rounded or flattened tears from twelve to twenty-five millimetres in diameter, or masses containing tears, greyish-white to dull yellow, darkening on keeping. Fresh tears usually tough at ordinary temperatures, hard when cold. Internally yellowish and translucent, or milk-white and opaque; freshly exposed surfaces often slowly become pink, then red, and finally reddish-brown. Odor strong, alliaceous and persistent; taste bitter, acrid and alliaceous. When triturated with *water* Asafetida forms a white emulsion. When the freshly fractured surface of a tear is touched with *sulphuric acid,* a bright red or brownish-red color is produced. The tincture obtained by macerating 0.5 gramme of Asafetida with 10 millilitres of *alcohol* (90 per cent.), filtered, made alkaline with *strong solution of ammonia,* and then largely diluted with *alcohol* (90 per cent.), does not exhibit a blue fluorescence (distinction from and absence of galbanum). Contains not more than 50 per cent. of matter insoluble in *alcohol* (90 per cent.). Ash not more than 15 per cent." *Br.*

Much commercial asafetida of prime appearance fails to come up to the requirements of the U. S. Pharmacopœia. Large quantities are said to be returned from the United States ports to Europe on account of their failure to contain the proper percentage of material soluble in alcohol. Macerated in water it produces a turbid red solution, and triturated with that fluid it gives a white or pinkish, milky emulsion of considerable permanence. Touched with nitric acid (sp. gr. 1.2) the tear becomes of a evanescent green color. O. Tunmann gives the following micro-chemical test for asafetida; sublime 0.05 gramme of powdered asafetida to obtain ferulic acid. The latter is identified by the development of a vanillin odor when warmed with a few drops of potassium permanganate solution.

Constituents.—Asafetida consists of 40 to 65 per cent. of resin, 20 to 30 of gum, 10 to 17 of volatile oil, and 2 to 15 of ash. Tschirch (*Harze und Harzebehälter,* 1900, p. 234) states that the resin is the *ferulaic ester of asaresinotannol* containing some free *ferulic acid,* and some vanilein, which latter is a produce of the oxidation of the ferulic acid. J. Polásek (*A. Pharm.,* 1897, ccxxxv, 125) found in the pure tears 61.40 per cent. of resin soluble in ether, which is regarded by him to be the ferulaic acid ester of asaresino-tannol; 0.60 per cent. of resin insoluble in ether, regarded to be free asaresinotannol; 25.10 per cent. of gum; 6.70 per cent. of volatile oil; 0.06 per cent. of vanillin; 1.28 per cent. of free *ferulaic* (*ferulic*) *acid;* 2.36 per cent. moisture; 2.50 per cent. impurities. *Asaresino-tannol* has the composition corresponding to the formula $C_{24}H_{35}O_5$. Umbelliferone was obtained as a secondary product of hydrolysis with sulphuric acid from asaresinotannol, and was also obtained from ferulic acid synthetically, guaiacol being produced at the same time. By nitrification of asaresino-tannol, picric acid is produced. (*A. Pharm.,* 1897, ccxxxv, 125, 132.) Hlasiwetz, 1866, and Barth (*Ann. Ch. Ph.,* cxxviii, 61), obtained *ferulic acid,* $C_{10}H_{10}O_4$, crystallizing in iridescent needles, by precipitating the alcoholic solution with lead acetate, washing the precipitate, and decomposing it with diluted sulphuric acid. Fused with potassium hydroxide, ferulic acid yields oxalic acid and carbon dioxide, several acids of the fatty series, and protocatechuic acids of the fatty series, and protocatechuic acid. The resin itself treated in like manner, after it has been freed from gum, yields resorcinol.

The odor of the gum-resin depends on the *volatile oil,* which may be procured by distillation with water or alcohol. It is lighter than water, colorless when first distilled, but becomes yellow with age, of an exceedingly offensive odor, and of a taste at first flat, but afterwards bitter and acrid. Hlasiwetz (*Ann. Ch. Ph.,* lxxi, 23) considers it a mixture, in variable proportions, of the sulphide and disulphide of a compound radical consisting of carbon and hydrogen (C_6H_{11}). Allyl persulphide, which is sublimed when oil of mustard is heated with potassium persulphide, is said by Wertheim to have an extremely intense odor of asafetida, a fact which justifies the supposition that it may be identical with the oil of that gum-resin. Semmler, in a later study (*B. Chem. G.,* xxiii, p. 3530, and xxiv, p. 78), states that it contains pinene and a second terpene in smaller amount, and in the higher boiling fractions, a disulphide, $C_7H_{14}S_2$; a disulphide, $C_{11}H_{20}S_2$; a body $(C_{10}H_{16}O)_n$; a disulphide, $C_8H_{18}S_2$; and $C_{10}H_{18}S_2$. Although the presence of umbelliferone has been reported by some authorities, it probably does not occur, naturally, in the drug but is easily formed by the action of hydrochloric or sulphuric acids on the ferulic acid of the resin.

Impurities and Adulterations.—Asafetida is often purposely adulterated; it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. It is generally conceded to be the worst adulterated drug upon the market. A factitious substance, made of garlic juice and white pitch with a little asafetida, has occurred in commerce. It is said to be sometimes mixed with wheat or barley flour or with earthy matters at the place of its production, the impurities sometimes exceeding 30 per cent. The gum-resin imported from the Persian Gulf and Bombay is largely adulterated with sand and other gum-resins. Patch (*Proc. A. Ph. A.,* 1905, p. 183) has found asafetida on the market which yielded 62, 62.5 and 73.3, respectively, of material insoluble in alcohol. The Belgian inspectors reported in 1905 finding as high as 75 per cent. of ash in some commercial samples. In spite of these figures Gehe & Co. report that the quality of the available asafetida has materially improved.

J. U. Lloyd, after examining a large number of samples of commercial asafetida, was convinced that it is impracticable to obtain the crude drug of the official standard, gypsum, carbonates, and other insoluble matters being present in large amounts. He did not find white turpentine or rosin in any of the samples; exhausting asafetida with alcohol and evaporating the alcohol carefully, he obtained an extract for which he proposed the name of *Purified Asafetida.* (*Ph. Rev.,* 1896.) H. William Jones (*Y. B. P.,* 1900, 503) purifies asafetida by pouring a concentrated alcoholic solution into water slightly acidulated with hydrochloric acid, collecting the precipitate, washing and drying it.

A few years ago a new method was proposed for the detection of adulteration in asafetida which depended upon the combining power of the purified resins with the lead in a standard solution of lead acetate. This method, the details of which will be found in *J. A. C.,* vol. ii, p. 86, is called the lead number. The method has not been found sufficiently reliable to warrant its inclusion among the official tests; Rippetoe (*A. J. P.,* 1913, p. 199) finds it to be subject to fluctuations as yet unexplained. Harrison and Self (*Ph. J.,* 1912, 205) present what they term a preliminary report on the investigation of this drug for the purpose of suggesting an improved method of standardization. They claim that there is good reason to believe that the virtues of asafetida are due not only to the volatile oil, but to the sulphur containing constituents of the volatile oil. They give abundant analytical data in support of their views and as showing how adulterations with other gum-resins may be readily detected. They state that if a gum-resin contains not less than 1.5 per cent. of sulphur it may unhesitatingly be pronounced as genuine asafetida. Bernegau and E'we propose a method for estimating asafetida in commercial tablets, pills, etc., depending upon extractions with hot chloroform under specified conditions. (*Proc. P. Ph. A.*, 1912, p. 305.)

Asafetida is sometimes kept in a powdered state, but this is objectionable, as the drug is thus necessarily weakened by the loss of volatile oil, and is more liable to adulteration. Powdered asafetida is best prepared by drying the crude drug over freshly burnt lime and then comminuting it at a low temperature.

Uses.—Asafetida appears to have been used in the East from the earliest times of which we have any record and notwithstanding its repulsive odor is at present much used in India and Persia as a condiment. In small amounts it gives the distinctive aroma to the type of sauce known as "Worcestershire." It is by some believed to have been imported into Europe as far back as the second century, but the earliest undoubted reference to it in European medical literature is in the twelfth century. Although it is without doubt capable of being absorbed from the intestinal tract in greater or lesser quantities there is no convincing evidence that after its absorption it exercises any distinct effect upon the system. Pidoux took a half an ounce at one dose without perceptible effects not ascribable to its local action. It has in the past been supposed to exercise a stimulant action upon the cerebral centers. The evidence in favor of this view is based upon the beneficial effects which have followed its administration in *hysteria* and conditions of *nervous exhaustion.* Its effects in these conditions, however, are entirely explicable on the grounds of the psychical impression made by taking a drug of so powerful odor and taste. On the other hand as a local stimulant to the mucous membranes, especially of the alimentary tract, it is a remedy of much value, thus it is a favorite carminative in the treatment of *flatulent colic;* it is often useful as an addition to laxative drugs in various types of *constipation.* There is evidence that after its absorption the volatile oil of asafetida is eliminated through the lungs and consequently it has been used as a stimulating expectorant in various forms of *bronchitis,* in *whooping cough,* and in *asthma.*

When used internally in adults it is generally preferable to administer it in the form of a pill on account of its disagreeable taste. In *colic,* especially in infants, it is often administered per rectum. For this purpose the emulsion of asafetida in the proportion of from one-half to one fluidounce to a pint of water may be employed.

J. W. Wood prepared *syrup of asafetida* by dissolving 256 grains of asafetida in two fluidounces of glycerin by the aid of a gentle heat and straining. He then dissolved 15 drops of oil of wintergreen, 5 drops of oil of cinnamon and 1 drop of oil of bitter almond in 3 fluidrachms of 95 per cent. alcohol, and added to it the above, together with enough syrup to make one pint. Each teaspoonful represents two grains of asafetida. (*A. J. P.*, 1874.)

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Emulsum Asafœtidæ, *U. S.;* Pilula Aloes et Asafœtidæ, *Br., N. F.;* Pilulæ Asafœtidæ, *U. S.;* Spiritus Ammoniæ Fetidus, *Br.;* Tinctura Asafœtidæ, *U. S., Br.*

ASARUM. N. F.

ASARUM Asar. [Canada Snake-root, Wild Ginger]

"Asarum consists of the dried rhizome of and roots of *Asarum canadense* Linné (Fam. *Aristolochiaceæ*). Asarum contains not more than 5 per cent. of foreign organic matter." *N. F.*

Radix Asari; Asaret de Canade, *Fr.;* Canadische Haselwurzel; Schlangenwurzel, *G.*

This plant is a low, perennial herb having an underground aromatic-bitter rhizome and root system. The rhizome bears several long petioled, radical, reniform leaves and also bell-shaped flowers that have a brownish-purple calyx.

Description and Physical Properties.—"*Unground Asarum.*—Rhizome horizontal, 5 to 17 cm. long, 2 to 4 mm. thick, occasionally branched, two edged when young, quadrangular when older, finely striate, more or less twisted; nodes enlarged with irregular scars from petioles and remains of pedicels; internodes with annular scars from scales; dark purplish brown externally; fracture short, internally whitish, starchy or resinous; roots few, 5 to 7 cm. long up to 1 mm. thick. Odor ginger-like or recalling serpentaria, non-irritating upon heating; taste pungent and slightly bitter.

"*Structure.*—Rhizome with thick bark of parenchyma and numerous oil cells; wood with about 12 fibrovascular bundles separated by broad medullary rays, and a large pith; parenchyma cells more or less filled with starch grains. Root with from four to six radial fibrovascular bundles.

"*Powdered Asarum.*—Starch grains simple or 2- to 4-compound, the individual grains 0.003 to 0.020 mm. in diameter; tracheæ with scalariform or reticulate thickenings, a few spiral; brownish fragments of epidermal tissue, parenchyma and numerous oil cells." *N. F.*

Asarum owes its activity to an acrid bitter resin and a volatile oil. According to Petersen, the chief ingredient of the latter is the methyl ether of eugenol, a compound which has been made synthetically but was not previously found in nature. According to the researches of Power and Lees (*Tr. Chem. Soc.*, 1902), the oil of *Asarum canadense* contains the following substances: a phenol, $C_9H_{12}O_2$; pinene, apparently a mixture of the d- and l- forms; d-linalool, l-borneol, l-terpineol, geraniol, eugenol-methyl-ether, a blue oil, of undetermined composition, consisting of oxygenated substances of alcoholic nature; a lactone, $C_{14}H_{20}O_2$, palmitic acid, acetic acid, and a mixture of fatty acids intermediate between acetic and palmitic acids.

Under the name of *asaron,* or *asarin,* a stereopten from the *A. Europeum* has been recommended as an antiseptic and tonic. *A.*

arifolium Michx. contains a volatile oil having a sassafras odor, sp. gr. 1.0585; see also *Schim. Rep.*, 1902, p. 12; also *Proc. Alabama Pharm. Assoc.*, 1910, 56–58.

Uses.—The medicinal properties of this drug are those of a feeble aromatic. From a half to one drachm (2–3.9 Gm.) may be used. It is employed as an aromatic adjuvant to tonic mixtures and infusions.

The *Asarum Europæum,* known popularly as *asarabacca* or *wild nard,* was formerly used for its local irritant action especially as an errhine and as a sialogogue. In doses of one-half to one drachm it acts as an emetic.

Off. Prep.—Syrupus Asari Compositus, *N. F.*

ASCLEPIAS. N. F.

ASCLEPIAS Asclep. [Pleurisy Root]

" Asclepias is the dried root of the *Asclepias tuberosa* Linné (Fam. *Asclepiadaceæ*). Asclepias contains not more than 5 per cent. of foreign organic matter." *N. F.*

Orange Milkweed Root; Butterfly Weed Root; Pleurisy Root; Wind Root; Orange Swallowwort; Racine d'Asclepiade tubereuse, *Fr.;* Knollige Schwalbenwurzel, *G.*

Asclepias tuberosa is a perennial herb with roughish-hairy stems branching at a summit and bearing umbels of orange flowers in a terminal corymb or scattered in racemes along the branches. The fruit consists of acuminate follicles, each containing numerous comose seeds. It grows from Ontario and Minnesota southward and southwestward. It is the only species of asclepias that is devoid of milk juice.

Besides the official species, various other members of this genus have been used in medicine. The *Asclepias Syriaca* L. (*A. Cornuti* Decaisne)—*milkweed* or *silkweed*—and the *A. incarnata* L. were formerly recognized by the U. S. Pharmacopœia (1840). The *A. Galoides* has been reported as the cause of death of horses and sheep by Marsh (*A. J. P.*, 1921, p. 274).

For microscopical differentiation for the various species of Asclepias see article by Fanchon Hart, *Year Book of American Pharm. Assoc.*, 1916, vol. v. For further description of unofficial species see *U. S. D.*, 19th edition, p. 1400.

Description and Physical Properties.—"*Unground Asclepias.* Irregularly fusiform; when entire 10 to 20 cm. long, 0.5 to 5 cm. thick, occasionally branched, usually cut or in broken pieces of variable size; externally pale orange-brown, or grayish brown; annulate above, the surface roughened by numerous intersecting fine intersecting grooves; bark thin; fracture tough, the broken surface granular and white, with pale yellow wood bundles and white medullary rays. Odor slight; taste bitterish and disagreeable, somewhat acrid.

"*Powdered Asclepias.* — Yellowish - brown; starch grains numerous, simple or 2- to 4-compound, individual grains up to 0.015 mm. in diameter, somewhat spherical or truncate and often with a cleft at center; calcium oxalate in rosettes up to 0.050 mm. in diameter parenchyma abundant, many of the cells with starch grains; stone cells up to 0.075 mm. in diameter, with strongly lignified thick walls, the latter with simple or branching pores; tracheæ with reticulate markings, occasionally bordered pores; fibers few, lignified and mostly with simple pores." *N. F.*

It contains a glucosidal principle, *asclepiadin,* which occurs as an amorphous body, is soluble in ether, alcohol and hot water. It also contains several resins and a trace of volatile oil.

Quackenbush (*A. J. P.*, 1889) isolated from both *A. tuberosa* and *A. Syriaca* a crystalline principle which he believed to be glucosidal. Whether this is the same substance as *asclepiadin,* previously found in *A. incarnata* by Gram (*A. E. P. P.*, 1884, xix, 319) is uncertain.

Uses.—In full doses asclepias is emetic and cathartic. Probably through its nauseating action in smaller doses it acts as a diaphoretic and expectorant. With the group of physicians who call themselves eclectics it was a popular remedy in the treatment of *pneumonia, bronchitis* and other pulmonary complaints. It was also employed in catarrhal *diarrheas,* in acute *rheumatism* and to promote the eruption in exanthematous *fevers.* It is probable that such therapeutic virtues as it may possess depends very largely upon its nauseating effect.

Dose, twenty to sixty grains (1.3–4 Gm.).

Off. Prep.—Fluidextractum Asclepiadis, *N. F.*

ASPIDIUM. U. S. (Br.)

ASPIDIUM [Male Fern]

" Aspidium consists of the rhizome and stipes of *Dryopteris Filix-mas* (Linné), Schott (Fam. *Dryopteris Filix-mas* (Linné), Schott (Fam. *Polypodiaceæ*). Aspidium yields not less than 6.5 per cent. of oleoresin, and not more than 3 per cent. of acid-insoluble ash. Only such portions as have retained their internal green color should be used." *U. S.* " Male Fern is the rhizome of Dryopteris Filix-mas, *Schott.* Collected late in the autumn, divested of its roots, leaves, and dead portions, and carefully dried. Should not be kept more than a year." *Br.*

Filix Mas, *Br.*, and *U. S.*, 1870; Stipites aspidii, Filicis Rhizoma, Male Shield Fern, Knotty or Sweet Brake, Basket Fern, Bear's-paw Root; Fougère Mâle, *Fr.;* Rhizoma Filicis Maris, *P. G.;* Wurmfarnwurzel, Waldfarnwurzel, Johanniswurzel, Farnwurzel, *G.;* Felce Maschio, *It.;* Helecho macho (Rhizoma de), *Sp.*

As the term Dryopteris was first used by Amman in 1739, and applied in 1763 by Adamson, as the name of the genus to which the Aspidium was applied in 1800 by Swartz, the use of the generic term Dryopteris would seem to be necessitated by the ordinary laws of botanic nomenclature. The synonyms for the male fern are extraordinarily numerous. We append some of them: *Aspidium Filix-mas,* of many authors; *Polypolium Filix-mas* Linn.; *Polystichum Filix-mas* Roth.; *Nephrodium Filix-mas* Rich.; *Lastrea Filix-mas* Presl.; *Tectarea Filix-mas* Cavan.; *Dryopteris Filix-mas* (L.) Schott; *Lophodium Filix-mas* Newm.; *Polypodium nemorale* Salisb.; *Polystichum durum et indur-*

atum Schur.; *Polystichum abbreviatum* De Candolle; *Aspidium wildeanum* Göppert; *Dryopteris affinis; Polypodium heleopteris.*

The Male Fern is of very wide distribution occurring in Greenland, Europe, Asia, Northern Africa and in some of the Polynesian Islands; in the Western Hemisphere it is found in the Rocky Mountains in North America and the Andes Mountains in South America.

The U. S. IX also recognized the *marginal fern, Dryopteris marginalis* (L.) Asa Gray (*Aspidium marginale* Sw.; *Polypodium marginale* L.) but it was dropped at the last revision. This fern is differentiated from the preceding by having the sori (fruit bodies) on the margin of the leaves instead of near the midrib. It is found in rocky woods and on banks in eastern North America from Nova Scotia to Alabama.

The male fern has a perennial, oblique rhizome, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe, or footstalk, and midrib are thickly beset with brown, tough, transparent scales; the frond itself is ovate-oblong in outline, the pinnæ being linear-lanceolate, tapering from base to apex. The fructification is in small dots on the back of each lobe, occurring close to the midvein.

Dryopteris Filix-mas yields the commercial variety of drug known as *European Aspidium.* Little of this variety has been imported since the outbreak of the war and none is arriving at the present writing. The oleoresin, however, is being imported from Europe. *Dryopteris marginale* yields the commercial variety known as *American Aspidium.* This variety is collected sparingly in scattered sections of the eastern and central United States but is no longer official.

It is probable that all of the species of this genus possess more or less anthelmintic properties. The activity of the *D. marginalis* is supported by the observations of Cressler (*A. J. P.*, 1878). According to Rosendahl (*P. J.*, 1911, lxxxvii, p. 35) the *Dryopteris dilatata* is indeed four times as active a poison to the tapeworm as the true aspidium. According to V. Penndorf (*Ap. Ztg.*, 1903), in Germany the rhizomes of *D. spinulosum* and *Athyrium Filix-fœmina* are frequently found mixed with those of the true male fern, in quantities varying from five to ninety per cent. The rhizomes of *D. Filix-fœmina* are readily recognized by having only two large dumb-bell-shaped steles. The rhizomes of *D. spinulosum* closely resemble those of the genuine drug, but it is stated that they can be distinguished by the numerous small glands found on the margin of their scales, the scales of *D. Filix-mas* having only two upon each. On account of this substitution, many of the German extracts of the male fern are said to contain *aspidin,* a yellow crystalline substance having a melting point of 124° to 125° C., which is found only in *D. spinulosum.* (*Ap. Ztg.*, 1903.) Lauren of Helsingsfors states that the extract of *D. spinulosum* is a very active tenicide, and is less apt to produce disagreeable sensations in the patient than is the official drug. He gives the dose as sixty grains (3.9 Gm.), followed by a laxative, and states that some Finnish apothecaries are especially noted for their fern extracts, because they use only the rhizome of *D. spinulosum.* (*Ap. Ztg.*, 1903.) Under the name of *filicone* there is used what is asserted to be the active principle of *D. spinulosum.* The dose is thirty grains.

On the Pacific slope the indigneous *D. rigida* Underw. is locally used against the tapeworm, and W. J. Bowman has found in it filicic acid and resin. Popular belief has long ascribed tenicidal virtues to our native *Asplenium Filix-femina,* commonly known as *Lady Fern.* It occurs in conical pieces from 8 to 13 cm. long, 2 to 5 cm. in diameter, of a reddish-brown color, covered with root fibers and leaf scars. According to R. Kürsten (*P. J.*, xxii, 1891), its active principle, *pannic acid,* is closely allied to filicic acid, differing in being especially soluble in strong alcohol, in subliming at 80° C., and is not yielding isobutyric acid when heated in a sealed tube with water. Pannic acid crystallizes is thin, shining, light yellow, rectangular prisms, melting at 187° C.

Under the name of *inkomankomo* or *uncomocomo,* the rhizome of *Aspidium athamanticum* (Hook.) Kuntze, has long been used by the South African Kaffirs, and has entered European commerce as *pannum.* In it Heffter (*A. E. P. P.*, 1897, 458) finds three well characterized and crystallized principles: *flavopannin, albopannin* and *pannol* (*pannic acid* of Kürsten). Heffter compares these three compounds with the three obtained from *D. Filix-mas* by Boehm. According to the experiments of A. Heffter, both *flavopannin* and *albopannin* are powerful muscle poisons, directly affecting the heart. (*A. E. P. P.*, Bd. xxxviii.)

The rhizomes of other species of fern are frequently substituted for the official, and in the dried state it is difficult to distinguish them. The varying results reported by physicians, when using this drug, can undoubtedly be ascribed to the employment of spurious male fern, or old brownish rhizomes which should have been thrown away.

The rhizome of aspidium apparently loses its therapeutic activity very rapidly when kept although Sollmann (*J. P. Ex. T.*, 1918, xii, p. 129) has shown that the oleoresin may retain its activity for many years.

As taken from the ground, the rhizome consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are 2 to 5 cm. in length, from 3 to 8 mm. thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the rhizome with thin silky scales of a light brown color. From near the bases of these remains

UNIVERSITY OF ILLINOIS
LIBRARY-CHEMISTRY

of the footstalks emerge numerous small rootlets. The whole rhizome, thus constituted, presents a somewhat flexible, cylindrical mass, 2.5 to 5 cm. thick, and from 7 cm. to 4 dm. in length. In this form, however, it is not usually found in commerce. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the rhizome attached to their base, where they are surrounded by the silky scales. These fragments, as seen in commerce, often appear as if long kept, and are probably, in general, much deteriorated by time.

Description and Physical Properties.—"*Unground Aspidium.*—Rhizome, 1 to 3 cm. in thickness, cylindraceous and nearly straight, or curved and tapering toward one end, usually split longitudinally, roughly scarred with remains of the stripe bases, or bearing several coarse, longitudinal ridges and grooves. Stipes, nearly cylindrical, but tapering toward one end, nearly straight or somewhat curved, 3 to 5 cm. in length, about 8 mm. in thickness; externally brownish-black, or if peeled, light brown; fracture short; internally pale green, spongy and exhibiting an interrupted circle of from 6 to 12 small vascular bundles; odor slight; taste sweetish, astringent, bitter and acrid.

"*Structure.*—An outer row of epidermal cells and several rows of brown, thick-walled hypodermal cells; parenchyma with intercellular spaces into which project characteristic glandular hairs; vascular bundles bicollateral, each surrounded by an endodermis, the tracheæ large, scalariform or reticulate; starch abundant, ellipsoidal or irregular, 0.002 to 0.025 mm. in length.

"**Assay.**—Aspidium yields not less than 6.5 per cent. of greenish oleoresin when prepared as directed under *Oleoresina Aspidii.*" *U. S.*

"From seven to fifteen centimetres or more in length; the rhizome itself about two centimetres in diameter. Entirely covered with the hard, persistent, curved, angular, dark brown bases of the petioles, which bear numerous brown membranous scales. Petioles green internally and exhibiting in transverse section about eight pale yellow fibrovascular bundles arranged in a diffuse circle (distinction from the petioles of Athyrium Filix fœmina, *Roth.*). Rhizomes brown externally, green internally. In transverse section, stalked secreting glands in intercellular spaces. Margins of the membranous scales with two-celled projections but no glands; at the base two minute glands (distinction from the rhizomes of certain other ferns). Feeble but disagreeable odor; taste sweetish and astringent at first, but subsequently bitter and nauseous." *Br.*

In collecting male fern, all the black, discolored portions should be cut away, the fibers and scales separated, and only the sound green parts preserved. These should be immediately, but carefully, dried and then pulverized; and the powder should be kept in small well-stoppered glass bottles. Powdered althæa leaves are sometimes used as an adulterant of powdered aspidium, giving the desirable light-green tint indicative of a good quality of drug. At other times the powder is said to consist entirely of the chaff and other inert material which the Pharmacopœia directs should be rejected.

Kraemer has reported that much of the aspidium in the American market consists of the large rhizomes of *Osmunda Claytoniana.* For distinction see *Proc. A. Ph. A.*, 1906, p. 345. Capelle discusses the characteristics of genuine aspidium and the differentiation of related species. (*Ap. Ztg.*, 1907, p. 433.)

Microscopic examination of the rhizome shows the following structural peculiarities, passing from periphery toward the center: (1) epidermis composed of brown polyhedral cells, some of which bear scaly hairs; (2) outer cortex (hypodermis) of several layers of thick walled, lignified cells, separating the epidermis from the inner cortex beneath; (3) inner cortex of several layers of isodiametric cells containing starch and separated from each other by intercellular air-spaces, many of which contain internal glandular-hairs; (4) fundamental parenchyma, resembling the last and forming the central matrix. Imbedded in this region are 6–12 fibrovascular bundles of concentric type arranged in an interrupted circle. Each bundle in cross section shows a central xylem consisting mainly of scalariform tracheids that are completely enveloped by a phloem of sieve tubes and phloem cells. Surrounding each bundle as a 1-to 3-layered pericambium and around this an endodermis or bundle sheath.

Microscopic examination of the stipe shows a similar arrangement of the tissues as found in the rhizome, but the bundles range in number from 6 to 10.

Constituents.—The activity of aspidium resides in its oleoresin. This contains as its most important anthelmintic principle an amorphous acid discovered by Kraft (*Ph. Ztg.*, 1903, p. 275) and called *filmaron.* Previous to this research various other principles had been separated. *Filicic acid* was discovered by Luck and later shown by Poulson (*A. E. P. P.*, 1891) to occur in a crystalline and amorphous condition; the former, which he believed to be the lactone of the latter, he found to be inactive and suggested that it be called *filicin.* Boehm, in addition, found *flavaspidic acid, albaspidin* and *aspidinol.* These substances are derivatives of phloroglucinol. By some they are believed to be decomposition products of filmaron.

Filmaron, $C_{47}H_{54}O_{16}$, is a bright, yellowish-brown, amorphous powder, insoluble in water, difficulty soluble in cold alcohol but readily so in most of the organic solvents and, with partial decomposition, in alkaline solutions. It shows a marked tendency to fuse together into masses and hence, is very difficult to pulverize. There is present also a peculiar tannin known as *filicitannic acid.* The rhizome contains about 5 per cent. of *filmaron.*

Aspidium may be assayed by first preparing the oleoresin, then dissolving 5 Gm. of this in ether and shaking out with 100 Gm. of 3 per cent. barium hydroxide solution after allowing to stand until clear, 86 Gm. of the barium hydroxide solution is decanted, acidulated with 3 Gm. of hydrochloric acid and shaken out with 25, 15 and 10 cc. portions of petroleum ether. The residue of filicic acid is dried at 100° C to constant weight. The final weight is multiplied by 25 to obtain the percentage. (See also *Am. Drug.,* 1897, p. 73.)

For further details of composition and assay see under *Oleoresina Aspidii.*

Uses.—Male fern was used by the ancients, and is mentioned as a vermifuge in the works of Dioscorides, Theophrastus, Galen and Pliny, and by some of the earlier modern writers. But it does not appear to have been generally known till about the year 1775, when the King of France purchased from Madame Nouffer, the widow of a Swiss surgeon, a secret remedy for tapeworm, which proved to be the powdered root of the male fern. As was first demonstrated by Straub (*A. E. P. P.,* 1902, xlviii, p. 1) the principles of aspidium paralyze the voluntary muscles of the higher animals as well as the analogous contractile tissue of the invertebrates. In smaller quantities these principles are stimulant to the central nervous system and may cause even tetanic convulsions.

Aspidium is used in medicine almost solely for the purpose of getting rid of various intestinal parasites, especially the *tapeworm.* As to its value in other forms of *helminthiasis* there is difference of opinion. Schultz (*J. A. M. A.,* 1911, lvii) reports 75 per cent. of cures in cases of *hookworm* infection, but Patterson (*T. G.,* 1908, xxxii), on the other hand, states that it has been found absolutely without value in this infection. Its action appears not to be so much to kill the parasite as to paralyze it so that it can be washed out of the alimentary canal with an active purge. For the latter purpose castor oil is often employed, but there is little doubt that its use increases the absorbability of the drug and hence adds to the danger of poisoning. For this reason calomel is generally to be preferred.

Besides its use as a vermifuge, aspidium has been recommended by La Nara (*J. des Pract.,* 1910) as a local application in *eczema* and *acne.*

Aspidium is a violent poison, the relative rarity of serious symptoms from its use being due to its non-absorbability. Under certain conditions, probably when there is a large amount of fatty matter in the bowel, it may be absorbed with unexpected readiness and give rise to serious and even fatal poisoning. Six drachms of it have caused death. (*L. L.,* 1882.) The common symptoms have been vomiting, diarrhea, vertigo, headache, tremors, cold sweats, dyspnea, cyanosis, convulsions and mental disturbances. In nearly half of the cases there was disturbance of vision and even blindness, which in a few instances remained permanently. According to Harnack (*M. M. W.,* 1912, lix, 1941), the blindness is due to spasm of the retinal vessels and subsequent optic atrophy. Prevost and Binet have found that in the lower animals, given hypodermically, the oleoresin produces violent dyspnea and death from arrest of the heart in systole, and Fröhner has found parenchymatous nephritis in animals fatally poisoned by it. The crude drug is to-day rarely used, preference always being given to the oleo-resin.

Filmaron has been used as a clinical vermifuge. Because of difficulties in pharmaceutical manipulation it is marketed in the form of a 10 per cent. solution in castor oil. The dose of filmaron is from eight to twelve grains (0.5 to 0.75 Gm.).

Dose, of aspidium rhizome in powder, sixty to one hundred and twenty grains (3.0–7.7 Gm.).

Off. Prep.—Oleoresina Aspidii, *U. S.* (*Br.*).

ATROPINA. U. S., Br.

ATROPINE Atrop.

"An alkaloid [$C_{17}H_{23}O_3N$] chiefly obtained from belladonna." *U. S.*

"Atropine, $C_{17}H_{23}NO_3$, is an alkaloid obtained from Atropa Belladonna, *Linn.,* and other plants of the natural order Solanaceæ." *Br.*

Atropia; Atropine, *Fr. Cod.;* Atropinum, *P. G.;* Atropin *G.;* Atropina, *It., Sp.*

Atropine is the optically inactive mixture of dextro- and laevo-hyoscyamine. Dextro-hyoscyamine does not occur in nature. Laevo-hyoscyamine occurs in the several species of *Solanaceæ* (see *Belladonnæ Radix*), the most abundant source being the Egyptian *Hyoscyamus muticus,* which also contains atropine. Atropine is manufactured, on the commercial scale, mainly from *Datura Stramonium.*

Description and Physical Properties.—"White, odorless crystals. *Caution.—Atropine is extremely poisonous.* One Gm. of Atropine is soluble in 455 cc. of water, 2 cc. of alcohol, about 27 cc. of glycerin, 1 cc. of chloroform, and in 25 cc. of ether, at 25° C. One Gm. is soluble in 90 cc. of water at 80° C., and in 1.2 cc. of alcohol at 60° C.

"Atropine melts between 114° and 116° C. Atropine is optically inactive. Its saturated aqueous solution is alkaline to litmus paper and to phenolphthalein T.S. Add a few drops of nitric acid to about 0.01 Gm. of Atropine contained in a porcelain dish, and evaporate the mixture to dryness on a water bath: a yellow residue is obtained. Add to the cooled residue a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide: an intensely violet color is produced. (*Hyoscyamine* and *hyoscine* produce the same color as Atropine, but the presence of *other alkaloids masks* the reaction.) Gold chloride T.S. produces in a solution of Atropine (1 in 50) in diluted hydrochloric acid, a lusterless precipitate. (*Hyoscyamine* yields a lustrous precipitate.)

"Five cc. portions of a solution made by dissolving 0.2 Gm. of Atropine in 1 cc. of normal sulphuric acid and 14 cc. of distilled water, do not respond to the platinic chloride test for *most other alkaloids* or the test for *apoatropine* or *belodonnine* described under *Atropinæ Sulphas.* Atropine complies with the tests for *ash* and *readily carbonizable substances* under *Atropinæ Sulphas.*" *U. S.*

"Colorless acicular crystals. Soluble in about 500 parts of *water,* readily soluble in *alcohol* (90 per cent.), in *chloroform,* and in *ether.* Melting point 114.5° to 115.5° C. Its aqueous solution has an alkaline reaction and powerfully dilates the pupil of the eye. 0.05 gramme dissolved in 5 millilitres of *water* acidified with *hydrochloric acid* yields with *solution of auric chloride* a lemon-yellow precipitate which, after recrystallization from boiling *water* acidified with *hydrochloric acid,* has a minutely crystalline character, is dull and pulverulent when dry, and melts at 137° to 139° C. (distinction from hyoscyamine). 0.01 gramme with 5 drops of *nitric acid* yields, when evaporated to dryness on a water bath, a residue scarcely yellow in color which, after cooling, assumes a violet color on moistening with freshly prepared *alcoholic solution of potassium hydroxide.* 0.05 gramme dissolves in 1 millilitre of *sulphuric acid* without coloration, and the solution remains colorless on the addition of 1 drop of *nitric acid.* 10 millilitres of a solution containing 1 part of Atropine in 80 parts of *water* slightly acidified with *hydrochloric acid* does not at once become cloudy on the addition of 4 millilitres of *solution of ammonia* (absence of apoatropine)." *Br.*

It is inflammable, giving off an odor like that of benzoic acid, and, when burned in the open air, leaves no residue. Kraut in 1864 demonstrated that atropine could be broken up by heating with hydrochloric acid or with baryta water in a closed vessel into a base, tropine, and an acid, tropic acid. Ladenburg (*B. Chem. G.,* 1880, xiii) succeeded in effecting the synthesis of atropine from these two constituents, which, when heated over a water bath in the presence of diluted hydrochloric acid, unite to form the alkaloid; later (*Ph. Ztg.,* 1902, 355), he produced tropine by the direct action of hydrobromic acid on tropidine. Willstätter produced tropidine synthetically and the following synthetic chain was completed: Glycerin, glutaric acid, suberone, tropidine, tropine, tropic acid, and atropine.

Tropic acid, $C_9H_{10}O_3$, crystallizes in prisms with a melting point of 117° C. According to King (*Tr. Chem. Soc.,* 1919, cxv, p. 490), it is a mixture of two optical isomers, dextro- and laevo-tropic acid. *Tropine,* $C_8H_{15}ON$, is a strongly basic substance crystallizing in rhombic tablets with a melting point of 63° C., soluble in water and several of the organic solvents. It is optically inert.

Ladenburg and others (see Pyman, *Tr. Chem. Soc.,* 1917, cxi, p. 1104) have formed a large number of esters of tropine to which the general name of *tropeines* has been given. Some of these have pronounced toxic effects, and one (homatropine) has found use as a valuable substitute for atropine.

Hinterberger states that an alcoholic solution of atropine, when cyanogen is passed through it, assumes a blood-red color, and, on spontaneous evaporation, deposits a red, syrupy liquid insoluble in water. The detection of atropine in small quantity is a matter of great difficulty; the best test is the physiological, which consists in placing the suspected liquid in the eye of a cat, or other animal, when, if the alkaloid be present, dilatation of the pupil will occur. According to Brunner, the best chemical test is the aromatic odor which is produced by adding the alkaloid and a little water to a hot mixture of sulphuric acid and potassium dichromate or ammonium molybdate. (*P. J.,* iv, 385.) Fabris believes that strychnine in the presence of atropine interferes with the toxicological identification of the latter by chemical tests, but a physiological test reveals the presence of both alkaloids. (*B. S. Ph. Br.,* 1894.) Wormley made comparative examinations of various tests for atropine, hyoscyamine, and hyoscine. (*A. J. P.,* 1894, 513.)

Uses.—The effects of atropine upon the system are due chiefly to two actions, namely, a stimulation of certain higher nerve centers and a paralysis of the peripheral endings of the nerves known as the autonomic (or parasympathetic) system. The autonomic nerves carry impulses to certain organs of unconscious life; among them are the secretory nerves for salivary, sweat, gastric, and probably all other glands except the kidney and mammæ; the vagus which carries inhibitory impulses to the heart, motor fibers to the bronchi and to a part of the intestines; the oculo-motor nerve which supplies the sphincter pupillæ and ciliary muscle. As atropine affects all of these nerves it is evident that it will produce a large number of changes in the bodily functions.

The earliest symptom of atropine poisoning is usually dryness of the throat. This is due to a paralytic action of the drug not only upon the chorda tympani nerve which supplies the salivary gland, but also probably to an action upon the mucous glands throughout the oral cavity. There is a corresponding decrease—although ordinarily only after somewhat larger dose—in the secretion of the sweat glands, of the digestive glands, and of the lachrymals; neither the kidney nor liver are affected. Concerning the mammary glands there is still some difference of opinion; pharmacologists have failed to demonstrate any effect upon these organs but clinicians continue to believe that the drug will cause a diminution in the secretion of milk. A little later in the action of atropine the pulse rate is increased through a paralysis of the cardio-inhibitory mechanism. [McGuigan (*J. A. M. A.*, 1921, lxvi, 1338) and Platz (*Zeitsch. f. Ges. Exper. Med.*, June 7, 1922) have both found that in man small doses of atropine cause a primary slowing of the pulse.] As a result of the more rapid heart action, but also largely from the effects upon the vasomotor center in the medulla, there is an increase in the blood pressure. The question of whether atropine has a direct stimulant influence upon the heart muscle is as yet undecided, but if it possesses any such action it is a feeble one. Its stimulant action upon the medullary center is also shown in the increased rapidity of breathing while that it possesses an action upon the cerebral centers is manifest by the delirium which follows toxic doses. The action upon intestinal peristalsis is probably a combination of various factors; through its paralytic action upon the branch of the pneumogastric nerve supplying the intestinal muscles it tends to counteract various spasmodic influences. At the same time, as has been shown by Magnus (*A. G. P.*, 1905, cviii, p. 1), it possesses an action upon the so-called Auerbach plexus by virtue of which it increases the size of the peristaltic wave and also tends to restore their rhythmicity. When directly applied in sufficient concentration it is capable of paralyzing the unstriped muscle. The dilatation of the pupil which may be caused by the systemic action of toxic doses of atropine, but is more commonly the result of its local application, is due to an action upon the peripheral endings of the oculomotor nerve. At the same time there is paralysis of accommodation through an effect upon the branches of this nerve which run to the ciliary muscle.

In the lower animals very large doses of atropine may cause increased reflexes, and even convulsions, through its effect upon the motor centers of the spinal cord, but this action is rarely seen in human poisoning. When brought in direct contact with either motor or sensory nerve endings it produces more or less complete abolition of their function.

Atropine is used in medicine for five purposes, namely, to check secretion, stimulate circulation, stimulate respiration, to overcome spasm of the involuntary muscles, locally for its effect upon the eye and externally as a local anodyne.

In the various forms of *colliquative sweating*, such as seen, for example, in *phthisis*, in *salivation*, as for instance, in mercurial poisoning, in *hyperchlorhydria*, atropine ranks as one of our most useful remedies. It is also of service to check the nasal secretions, as for instance in *acute coryza* or *hay fever*. In *galactorrhea* and threatened *mammary abscesses* belladonna plasters are routinely applied with the idea that the atropine in them may diminish the lacteal secretions, but as pointed out above, it is doubtful whether the drug possesses any such power.

As a circulatory stimulant atropine is of great value in severe emergencies, such as *surgical shock* or *collapse*. Its value in these conditions is due in part to the stimulating action on the vasomotor center and also in part to the effect upon the nerves of the skin which tend to check the excessive sweating which is characteristic of these states and thereby prevent the loss of animal heat. In the milder forms of circulatory failure it is ordinarily not to be recommended because the drying up of the secretion is often a source of great discomfort to the patient. As a respiratory stimulant it is of service, especially in the treatment of *poisoning* by various depressants, such as opium, chloral, and the like. It should be borne in mind that large doses of atropine are depressant and the physician should never give more than one-fiftieth of a grain when used either as a circulatory or respiratory stimulant.

In spasmodic affections involving the unstriped muscles, such as the *colica pictonum* and the *asthmatic paroxysm*, atropine is perhaps the most certain symptom remedy which we possess. In the latter affection it is usually best administered by inhalation; for this purpose it may be volatilized by burning one of the plants containing it. (See *Stramonium*.) In *whooping cough* and *dysmenorrhea* it is sometimes of value, but its action is much less certain. Certain cases of nocturnal *enuresis* appear to be due to a hyper-irritability of the muscle in the walls of the bladder and in these patients full doses of atropine are of the greatest service. The injection of atropine into the substance of the trapezius muscle in cases of *wry-neck*, for the purpose of paralyzing the motor nerve supplying it, while commonly recommended in text-books, generally does not prove of avail. Allied to its antispasmodic action is the power of atropine to regulate as well as increase the movements of the bowel. For this purpose it is habitually added to laxative mixtures for the purpose of preventing griping as well as to enhance the aperient effect. Massive doses (as high as one-twentieth grain) have also been used with apparent favorable results in the treatment of *ileus*. Wolf believes that atropine has an effect on the labyrinthine nerves of the ear and therefore recommends it in *sea-sickness*.

In ophthalmology atropine is a remedy of extreme service. It is used both for the purpose of dilating the pupil and of paralyzing the muscles of accommodation. Its action is so slow and persistent that in cases where only temporary effects are desired, as, for example, the fitting of glasses, it has been largely abandoned for more rapidly acting drugs, but in inflammatory conditions of the eye, as in *iritis*, *keratitis*, etc., the very persistency of its effect makes it of extreme usefulness. For this purpose one or two drops of a 1 per cent. solution may be instilled into the eye at such intervals as may be deemed necessary. The same purpose may be accomplished by inserting beneath the eyelid small gelatin disks containing atropine. (See *Lamellæ Atropinæ.*)

Locally atropine in the form of an ointment and the plaster of belladonna is largely used in various painful conditions, but its use does not seem highly rational for this purpose.

Toxicology.—Atropine poisoning may occur from the ingestion of any of the numerous plants of which it is the active principle, most frequently, however, from either belladonna or the widespread stramonium. It should be remembered that severe poisoning may follow the external application either of the ointment or plaster of belladonna. The symptoms are dryness of the throat, dilatation of the pupil, rapid, hard pulse, hurried respirations, the skin warm and dry, the face flushed and frequently there is an erythematous rash somewhat resembling that of scarlet fever. (For description and literature of atropine eruptions see Knowles, *A. J. M. S.,* July, 1911.) The most striking of the symptoms, however, is the peculiar delirium. In the earlier stages this manifests itself simply by profuse and somewhat incoherent talkativeness, but later there is complete obfuscation often with hallucinations, sometimes more or less maniacal in character. After large doses a stage of depression may develop with stupor, weakening of the pulse, and respiratory failure. The condition, though alarming, usually ends in recovery. In case of doubt as to the cause of the condition a presumptive diagnosis can be made by instilling a drop or two of the urine from the patient into the eye of a cat. In most cases of atropine poisoning sufficient of the drug is eliminated through the kidneys to cause dilatation of the pupil.

In the *treatment* after emptying the stomach with the stomach tube or suitable emetics, twenty minims of the compound solution of iodine should be given as the best chemical antidote. Morphine may be used cautiously for the purpose of quieting the delirium, but as the real danger in the case is from respiratory failure it should not be given in large dose. Physostigmine is almost a complete physiological antagonist of atropine and would probably prove useful in cases of poisoning. Symptoms of respiratory and circulatory failure may best be met by the use of strychnine and caffeine.

The hypodermic *dose* of atropine may be set down as one one-hundred-and-fiftieth of a grain (0.0004 Gm.), the dose by the mouth as one one-hundredth of a grain (0.0006 Gm.), although in serious cases these amounts may be much exceeded. Thus in *ileus* German clinicians have given as high as the one-twentieth of a grain (0.003 Gm.) at a dose. On the other hand in susceptible persons, one-hundredth of a grain (0.0006 Gm.) will produce decided dryness of the throat, and one-fiftieth of a grain (0.0013 Gm.) is alleged to have caused toxic symptoms. As atropine itself is nearly insoluble, the sulphate should always be preferred. For application to the sound skin, the form of ointment or oleate is most convenient. The ointment may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. The ointment of belladonna, is, however, usually preferred.

When solution of atropine sulphate is used for dilating the pupil, it may be either dropped into the eye within the lower lid, or introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular disks of gelatin, made by mixing the solution with gelatin and evaporating so as to produce a thin film, which is to be cut into circular pieces. (See *Lamellæ Atropinæ.*) These have the advantage over paper that they do not require to be subsequently removed from the eye.

The solution of atropine or its salts is very prone to have developed in it a fungous growth with consequent decomposition of the alkaloid. Simon (*J. A. M. A.,* 1915, lxiv, 705) has shown that a solution of atropine may become entirely inert in three days.

Dose, of atropine, one two-hundredth to one-fiftieth of a grain (0.0003–0.0013 Gm.).

ATROPINÆ SULPHAS. U. S., Br.

ATROPINE SULPHATE Atrop. Sulph.

"$(C_{17}H_{23}O_3N)_2H_2SO_4.H_2O$." *U. S.*

"Atropine Sulphate, $(C_{17}H_{23}NO_3)_2,H_2SO_4$, is the sulphate of the alkaloid Atropine." *Br.*

Sulphate of Atropia; Sulfate d'Atropine, *Fr. Cod.;* Atropinum Sulfuricum, *P. G.;* Schwefelsaures Atropin, Atropinsulfat, *G.;* Solfato di atropina, *It.;* Sulfato de atropina, *Sp.*

Atropine sulphate may be prepared by the interaction between a solution of atropine in ether and of sulphuric acid in strong alcohol, and a formula for its manufacture was official in the U. S., 1870. Considerable care is necessary in the preparation of the salts of this alkaloid because of the great facility with which atropine is decomposed. For details of the formerly official method see *U. S. D.,* 20th ed., p. 208.

Description and Physical Properties.—"A white, odorless, crystalline powder. It is efflorescent in dry air. *Caution.—Atropine Sulphate is extremely poisonous.* One Gm. of Atropine Sulphate is soluble in 0.4 cc. of water, 5 cc. of alcohol, 2.5 cc. of glycerin, 420 cc. of chloroform, and in 3000 cc. of ether, at 25° C. One Gm. is soluble in 2.5 cc. of boiling alcohol.

"Melting point: not below 188° C. Add a few drops of nitric acid to about 0.01 Gm. of Atropine Sulphate, contained in a porcelain dish, and evaporate the mixture to dryness on a water bath: a yellow residue is obtained. Add to the cooled residue a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide: an intensely violet color is produced. (*Hyoscyamine* and *hyoscine* produce the same color as Atropine, but the presence of *other alkaloids* masks the reaction.) Gold chloride T.S. produces in an aqueous solution of Atropine Sulphate (1 in 50) a lusterless precipitate. (*Hyoscyamine* yields a lustrous precipitate.) Barium chloride T.S. produces in an aqueous solution of Atropine Sulphate a white precipitate which is insoluble in hydrochloric acid.

"An aqueous solution of Atropine Sulphate (1 in 20) is neutral to litmus paper. The ash from 0.1 Gm. is negligible. One-tenth Gm. of Atropine Sulphate dissolves in 2 cc. of concentrated sulphuric acid without producing more than a slightly yellow coloration (*readily carbonizable substances*), and the solution becomes only light yellow upon the addition of 0.1 cc. of nitric acid (*many other alkaloids*). In an aqueous solution of Atropine Sulphate (1 in 50), mixed with a few drops of hydrochloric acid, platinic chloride T.S. produces no precipitate (*most other alkaloids*). An aqueous solution of the salt (1 in 60) is rendered turbid by sodium hydroxide, but no turbidity is produced immediately upon the addition of 2 cc. of ammonia T.S. to 5 cc. of the solution (*apoatropine or belladonnine*)." *U. S.*

"Nearly colorless, crystalline, somewhat hygroscopic. Soluble in less than 1 part of *water*, and in 4 parts of *alcohol* (90 per cent.), the solutions being neutral to *litmus* and, even when largely diluted, dilating the pupil of the eye. Melting point from 189° to 190° C. 0.05 gramme dissolves in 1 millilitre of *sulphuric acid* without coloration, and the solution remains colorless on the addition of 1 drop of *nitric acid.* 10 millilitres of an aqueous solution (1 in 60) do not at once become cloudy on the addition of 4 millilitres of *solution of ammonia* (absence of appoatropine). An aqueous solution, not too dilute, yields with *solution of sodium hydroxide* a white precipitate which, when washed and dried, responds to the tests described under 'Atropina.' Yields the *reaction* characteristic of sulphates. Loses not more than 2 per cent. of moisture when dried at 105° C." *Br.*

Uses.—The effects of the salt on the system are precisely the same as those of atropine, and it may be used in the same dose. Its great advantage over the alkaloid is its solubility in water.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

AURANTII CORTEX INDICUS. Br.

INDIAN ORANGE PEEL

"Indian Orange Peel is the fresh and the dried outer part of the pericarp of varieties of Citrus Aurantium, *Linn.,* grown in India and Ceylon." *Br.*

It is thus described: "Possesses the pleasant aromatic odor and bitter taste characteristic of Bitter Orange Peel derived from Citrus Aurantium, var. Bigaradia, *Hook, f.* Inner surface retains not more than a very small amount of the white spongy part of the pericarp." *Br.*

In India and the Eastern divisions of the Empire, Indian Orange Peel, fresh or dried, may be employed in making the official preparations for which Fresh or Dried Bitter Orange Peel is directed to be used.

AURANTII CORTEX RECENS. Br.

FRESH BITTER-ORANGE PEEL

"Fresh Bitter-Orange Peel is the fresh outer part of the pericarp of Citrus Aurantium, var. Bigaradia, *Hook. f.*" *Br.*

It is thus described: "Outer surface red or deep orange-red in color, and generally rough. Inner surface retains not more than a very small amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." *Br.*

AURANTII DULCIS CORTEX. U. S.

SWEET ORANGE PEEL Aurant. Dulc. Cort.

"Sweet Orange Peel is the fresh, outer rind of the ripe fruit of *Citrus Aurantium* var. *sinensis* Linné (Fam. *Rutaceæ*)." *U. S.*

The citrus trees, lemon and orange, appear to have been cultivated in ancient India as far back as history goes, the names of the fruits being of Sanskrit etymology. There is considerable difficulty in classifying the species of this genus, partly because of similarities and partly because of tendency to hybridization; some regard the different fruits as distinct species, while others consider them as merely varieties. Engler (*Die naturlichen Pflanzenfamilien,* 1897) divides the species *Citrus Aurantium* L. into a number of sub-species, some of which have been considered by others as distinct species, as follows:

C. aurantium amara L. (*C. Bigaradia* Duhamel; *C. aurantium* var. *Bigaradia* Hook. f.) known as the *bitter* or *Seville orange,* or *Bigarade; C. aurantium sinensis* Gallesi (*C. aurantium* var, *dulcis* L.), *sweet orange* or *Malta orange; C. aurantium Bergamia* (Risso et Poyteau) Wight et Arnott which is the *Bergamot;* and several other varieties which are not of medicinal importance.

In all its varieties the orange tree is a beautiful evergreen growing to the height of about 30 feet and having the fruit mingled in every stage of its growth with blossoms and foliage. It is a native of China and India, was introduced into Europe by the Arabians about the ninth century and is now cultivated in subtropical lands all over the world. The American supply is grown chiefly in California, Florida and the West Indies. The stem of the tree is rounded, much branched, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green color. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with volatile oil, and when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and have wings or lateral appendages. The flowers, which have a delightful odor, are large, white, and attached by short peduncles, singly or in clusters, to the smallest branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct groups, and support yellow anthers. The ovary is roundish, and bears a cylindrical style, terminated by a globular stigma. The fruit is a hesperidium, often somewhat flattened at its base and apex, rough, of a yellow or orange color, and divided internally into a number of vertical loculi, each containing from two to four seeds, surrounded by a pulp. The rind of the fruit consists of a thin exterior layer, abounding in schizo-lysigenous cavities filled with a fragrant volatile oil, and of an interior one, which is thick, white, spongy, bitterish, and inodorous.

The fruit of the bitter orange is smaller than that of the sweet orange and of a deeper color, more acid and slightly bitterish in taste. It is round but flattened above and below, and has a smooth, thin, delicate rind. The commercial supplies come chiefly from the south of Spain and Sicily, but it is also cultivated in Florida. The flowers of this tree yield a very fragrant oil (see *Oleum Aurantii Florum*). They were formerly recognized by the U. S. P. (1880) and were described as follows: "about half an inch (12 mm.) long; calyx small, cup-shaped, five-toothed; petals five, oblong, obtuse, rather fleshy, white and glandular-punctate; stamens numerous, in three or more sets; ovary globular, upon a small disk, with a cylindrical style, and a globular stigma; odor very fragrant; taste aromatic and somewhat bitter." *U. S.,* 1880. The dried flowers were formerly used on the continent of Europe as a gentle nervous stimulant. The fresh flowers may be kept for some time by mixing them well with half their weight of sodium chloride, pressing the mixture in a suitable jar, and keeping it well closed in a cool place.

The leaves, which are bitter and aromatic, also yield a volatile oil which is often mixed with the oil of the blossoms.

The fruit of the sweet orange is larger and of a lighter color, and the pulp is less acid and free from bitterness. Because of its superior flavor this orange is usually given the preference for eating, and several variations have been produced. Among these are the seedless variety called the *navel orange,* so popular in this country, and the *blood orange,* the pulp of which has a red instead of yellow color.

The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning-lathe, are sometimes found in commerce under the name of *orange berries.* They are sub-globular, 5 to 20 mm. in diameter, of a grayish or greenish-brown color, fragrant odor, and bitter taste, and are said to be used for flavoring cordials. A volatile oil is obtained from them by distillation, known to the French by the name of *essence de petit grain,* and employed for similar purposes with that of the flowers. The oil, however, which now goes by this name is said to be distilled from the leaves, and those of the bitter orange yield the best. The oils from the unripe and the ripe fruit have a rotating power to the right, the latter much greater than the former; and this property might serve to distinguish them from the oil of the leaves. Several of the oils from the *Rutaceæ* deposit a crystalline substance, differing from camphor.

The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, as one pares an apple. When the object is to use the fresh rind for certain pharmaceutical purposes, as for the preparation of the *confection of orange peel,* it is best separated by a grater, carefully avoiding the grating of the white portion which contains the bitter principle. The dried peel sold in the shops is usually that of the Seville orange, and is brought chiefly from countries adjacent to the Mediterranean.

Bitter orange peel has a grateful aromatic odor, which depends upon the volatile oil contained in its schizo-lysigenous cavities, and a warm, bitter taste.

Description and Physical Properties.—"*Unground Bitter Orange Peel.*—Thin, irregular bands (ribbons) or quarters; outer surface yellowish- or reddish- or greenish-brown with numerous, minute pits and fine reticulate ridges; inner surface whitish with many slight conical projections and fine anastomosing lines formed by the vascular bundles; fracture hard, short; odor fragrant and aromatic; taste aromatic and bitter.

"*Structure.*—An epidermis of small, angular cells; an outer parenchyma of thick-walled cells containing chloroplasts or chromoplasts and occasionally calcium oxalate prisms, and bearing the large oil reservoirs, arranged mostly in two irregular rows; an inner spongy parenchyma of branched cells surrounding large intercellular spaces, and bearing delicate, anastomosing vascular bundles.

"*Powdered Bitter Orange Peel.*—Yellowish-gray or light brown; fragments of parenchyma abundant, the cells walls from 0.004 to 0.012 mm. thick; tracheæ very small with close spiral markings or simple pores; calcium oxalate prisms from 0.020 to 0.045 mm. long.

"Powdered Bitter Orange Peel is colored yellow upon the addition of sodium hydroxide T.S." *U. S.*

"In thin strips. Outer surface deep orange-red and rough. Inner surface retains not more than a very small amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." *Br.*

The Br. Pharmacopœia requires that the other surface both of the fresh and of the dried bitter orange peel shall be of a deep orange-red color, and rough and glandular.

The *sweet orange peel* is described officially as follows:

"*Unground Sweet Orange Peel.*—The outer, orange-yellow layer recently separated by grating or paring and consisting of epidermal cells, parenchyma and oil reservoirs with globules of volatile oil; odor highly fragrant; taste pungently aromatic. The inner, white portion of the rind should not be used." *U. S.*

For the preparation of powdered bitter orange peel the German Pharmacopœia directs that the drug should be previously dried over freshly burnt lime. Bitter orange peel is sometimes adulterated with sweet orange peel. The latter is distinguished by the pieces being thinner and of a more orange-red color. They are less aromatic and less bitter. The following test which is distinctive for bitter orange peel is recognized by the Netherland Pharmacopœia: the section of the fruit is mounted in a solution of potassium bichromate slightly heated when the tissues become colored brown. This reaction does not take place with sweet orange peel. A distinctive test for the latter is the use of fuming nitric acid (containing 55 per cent. N_2O_5) which gives a dark green color distinguishing it from bitter orange peel which is colored brown.

Constituents.—Tanret found in the rind of the bitter orange, (1) a crystalline acid, $C_{44}H_{28}O_{14}$; (2) a non-crystalline resinous body; (3) the glucoside *hesperidin;* (4) *isohesperidin,* a crystalline glucoside isomeric with hesperidin; (5) *aurantiamarin,* another glucoside to which, in part, the bitterness of the peel is due. (*P. J.*, 1886, 839.) *Hesperidin,* $C_{22}H_{26}O_{12}$, was discovered by Lebreton in 1828. Treated with diluted acids it yields *hesperetin,* $C_{16}H_{14}O_6$, and glucose. Hesperidin has a fusing point 250° to 251° C., and may be prepared by Paterno and Briosi's process, as follows: The cut and bruised oranges are covered with diluted alcohol, solution of potassium hydroxide added in excess, the liquor filtered after two days, and impure hesperidin precipitated by hydrochloric acid; the precipitate is boiled with acetic acid for ten minutes, and, after cooling, filtered from the resinous mass left. The hesperidin gradually separates from the filtrate upon standing, in white fine needles. From 4000 oranges about 6 ounces av. of the principle were obtained. (*B. Chem. G.*, 1876, 250.)

Orange peel contains also albumen, pectin, resin, a trace of fixed oil, volatile oil, and a principle resembling tannin in its action on salts of iron and notable amounts of certain vitamins, according to recent investigations. Fresh orange peel, the waste material from the orange oil industry, has become one of the sources of commercial pectin. The bitter principles are much more abundant in the white spongy inner portion of the peel than in the outer yellowish layer. For description of the volatile oil see *Oleum Aurantii.*

Uses.—Bitter orange peel is a mild tonic, carminative, and stomachic; the sweet is simply aromatic; but neither is much used alone. They are chiefly employed to communicate a pleasant flavor to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. They are a frequent and useful addition to bitter infusions and decoctions, such as those of gentian, quassia, calumba, and Peruvian bark. It is obviously improper to subject orange peel to the action of heat, as the volatile oil is thus driven off. Violent colics, convulsions, and even death have been caused in children by eating large quantities of the rind. When orange peel is used simply for its agreeable flavor, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

Dose, from half a drachm to a drachm (2.0–3.9 Gm.).

Off. Prep.—Syrupus Aurantii, *U. S., Br.* (from Tincture); Tinctura Aurantii Dulcis, *U. S.;* Vinum Aurantii (from Fresh Peel), *Br.*

AVENA SATIVA. N. F.

OAT Even. Sat.

"Oat is the grain of *Avena Sativa* Linné (Fam. *Graminæ*). Oat contains not more than 5 per cent. of other seeds or of foreign organic matter." *N. F.*

Oatmeal; Avenæ Farina; Oatmeal; Avoine, Farine d'Avoine *Fr.*; Hafermehl, *G.*; Farina dell' Avena, *It.*; Harina de Avena, *Sp.*

Avena sativa L., or the common cultivated oat (Fam. *Gramineæ*), is so well known that a minute description would be superfluous. It is an annual, specifically distinguished by its loose panicle of spikelets and its elongated hairy grain, firmly enveloped by a "hull" consisting of a lemma and palet. It was known to the ancients, and is now cultivated in all civilized countries; but its original locality has not been satisfactorily ascertained. It grows wild in Sicily, and is said to have been seen by Anson in the island of Juan Fernandez, off the coast of Chili. The seeds deprived of their husks are sometimes known as *groats.* As a human food coarsely ground oatmeal is usually preferred to the fine meal, and the grain grown in a northern climate is superior to that produced further south. The market preparations at present are hardly to be called meals for instead of being ground the grain is crushed between heavy rollers sometimes with heat and moisture as accompaniments of the process.

Description and Physical Properties.—"*Unground Oat.*—Pale yellow or pale yellowish-green; up to 1.5 cm. in length and about 3 mm. in diameter, tapering toward each end, the base somewhat contracted, slightly protruding and with an elliptical scar, the apex pointed, showing the more or less broken upper part of the lemma and palet, the former surrounding the grain except on the ventral side where there is a distinct longitudinal groove, the latter usually exhibiting a minute stalk at the base; outer surface of the lemma glabrous with five or more longitudinal veins on the dorsal surface; above the center, a scar or, rarely, remains of a straight or slightly twisted awn (presence of strongly twisted awn indicates *Wild Oat*); within the groove a narrow, thinly-membranous, two-veined palet or scale; fruit or naked grain tapering toward either end, a distinct longitudinal groove on the ventral side, at the micropylar end of which occurs a wart-like excrescence or caruncle, at the opposite end a dense mass of long slender hairs which also occur less abundantly over the surface of the fruit. Odor slight; taste starchy.

"*Structure.*—Lemma; outer epidermis chiefly of elongated cells with beaded and heavily salicified and lignified walls and rounded ends, between the elongated cells a few crescent-shaped or circular cells, the latter fitting into the concave side of the former and each with heavily salicified walls, a few elliptical stomata and near the margin straight or slightly curved unicellular non-glandular hairs with thick lignified walls; hypodermis composed of about five layers of fibers with thick, partially beaded, lignified walls, the cells with taper-pointed ends and up to about 1 mm. in length and spongy parenchyma composed of irregularly shaped cells with large intercellular spaces. Palet; margins with numerous sharp pointed, straight or slightly curved, unicellular hairs with lignified walls; elliptical stomata up to about 0.040 mm. in length and in rows parallel to the keel; hypodermis of about three layers of cells otherwise resembling the glume but with thinner, less heavily developed tissue. Fruit: epicarp of longitudinally elongated cells, some of which give rise to unicellular, lignified-walled, pointed hairs, other layers of tissue of pericarp and seed coat of more or less collapsed cells, outer layer of endosperm usually one cell thick, the cells filled with protein, remaining tissue of endosperm composed of parenchyma chiefly filled with starch grains; broad spindle-shaped embryo about 2 mm. in length embedded in the endosperm near the micropylar end.

"*Powdered Oat.*—Whitish; fragments of epicarp with thin-walled cells up to about 0.400 mm. in length, from some of the latter arising slender pointed hairs up to 2 mm. in length, 0.020 mm. in diameter at the base, larger at the middle and with lumina up to 0.009 mm. in diameter and walls up to 0.008 mm. in thickness; fragments of glume with characteristic tissues; occasional fragments of palet with coarse unicellular hairs up to 0.250 mm. in length; irregular portions of endosperm tissue with cells containing rounded or ellipsoidal, many-compound starch grains, the compound grains up to 0.060 mm. in diameter with individual grains polygonal or spindle-shaped up to 0.010 mm. in diameter." *N. F.*

Constituents.—A very elaborate report on the composition of American cereals by Clifford Richardson (*Department of Agriculture, Bulletin* No. 9) gives as the average ratio in oats from all parts of the country 70 per cent. of kernel to 30 per cent. of husk. According to the same authority, the composition of the kernel (average of 179 analyses) is as follows: Water, 6.93 per cent.; ash, 2.15; oil, 8.14; carbohydrates, 67.09; fiber, 1.38; albuminoids, 14.31; corresponding to nitrogen per cent. 2.28. The nitrogenous principle has been called *avenin,* and somewhat resembles legumin. Ritthausen (*Die Eiweisskörper, Bonn,* 1872, 135) considers Nortin's avenin to have been a mixture of legumin or vegetable casein and a vegetable gluten containing sulphur, to which he gives the name *gliadin,* the legumin, however, predominating.

Uses.—Gruel made with fine oatmeal affords a nutritious, bland aliment, which, from its somewhat laxative tendency, is often preferable to other amylaceous preparations. *Oatmeal gruel* may be prepared by boiling an ounce of the meal with three pints of water, to a quart, straining the decoction, allowing it to stand until it cools, and then pouring off the clear liquor from the sediment. Sugar, lemon juice, or wine may be added to improve its flavor.

Diuretic properties have been attributed to the oatmeal, but probably incorrectly. It probably has no therapeutic properties not possessed by all cereal grains.

The N. F. gives the *dose* as sixty grains (4 Gm.) but indefinite amounts may be used.

Off. Prep.—Elixir Hydrastis Compositum, *N. F.;* Fluidextractum Avenæ Satival, *N. F.*

BALSAMUM PERUVIANUM. U. S., Br.

BALSAM OF PERU Bals. Peruv. [Peru Balsam]

"Balsam of Peru is obtained from *Toluifera Pereiræ* (Royle) Baillon (Fam. *Leguminosæ*)." *U. S.* "Balsam of Peru is a viscid balsam exuded from the trunk of Myroxylon Pereiræ *Klotzsch,* after the bark has been beaten and scorched." *Br.*

Balsamum Peruvianum Nigrum; Balsamum Indicum; Baume du Pérou *Fr. Cod.*; Baume de Sonsonate, *Fr.*; Balsamum peruvianium, *P. G.*; Peruvianischer Balsam, Perubalsam, *G.*; Balsamo peruviano, Balsamo del Peru, *It.*; Bálsamo del Peru liquido, Bálsamo de San Salvador, Bálsamo Peruviano negro, *Sp.*

The name "*Toluifera Pereiræ*" assigned to the tree yielding Balsam of Peru by Baillon seems inappropriate in respect to its generic part, since it means Tolu bearing. We are, accordingly, inclined to prefer the name for this plant as given in the British Pharmacopœia, *Myroxylon Pereiræ* Klotzsch. There is a difference of opinion as to the classification of this plant. Baillon and also Hartwich and Jama (*Schweiz. Woch. Chem. Pharm.*, 1909, xlvii, 641) consider that it is a variety of the *M. Balsamum.*

The term Balsam of Peru is a survival of the times when the products of the Spanish colonial coast were assembled at Callao, Peru, for shipment to Europe. This fact has caused Gane and Webster to assert that Balsam of Peru is misbranded under the Foods and Drugs Act in that it does not come from Peru. (*Drug Topics,* 1910, p. 4.)

Myroxylon Pereiræ is a tall tree with ash-colored bark which attains the height of 50 feet. At about 5 feet above ground the trunk divides into horizontal or slightly obliquely ascending branches which combine to form an egg-shaped crown. These bear alternate, imparipinnate leaves with the usually 5, at least 4, less frequently 6, coupled leaflets and an extra terminal one. The leaflets almost always are alternate along the midrib, oblong to oval-oblong in shape, acute at apex and rounded at the base. The blooming axillary twigs are marked by a scattering of point-shaped bright lenticels. Each of these terminates in a loose raceme of nodding flowers. Each of the flowers possesses a green cup-shaped slightly toothed calyx, a bluish-white, papilionaceous corolla, 10 stamens with white filaments and red anthers (the latter constituting the most showy portion of the flower) and a green pistil. The fruit is a yellowish-brown legume. This tree grows in Central America, in the State of San Salvador, upon the Pacific coast. It is found in the wild forests, singly or in groups, but the trees are owned by individuals. Charles Dorat states that it is never found at a greater height on the mountains than one thousand feet, that it begins to be productive after five years, and continues to yield for thirty years or more, and that the aroma of its flower is perceived at the distance of one hundred yards. The tree has been introduced into the island of Ceylon.

The balsam is collected within a small district denominated the Balsam Coast, extending from Acajutla to La Libertad. Early in November or December the bark is beaten on four sides of the trunk, so as to separate it from the wood without breaking it, intermediate strips being left sound, in order not to destroy the life of the tree. The bruised bark soon splits, or cuts are made in it. Five or six days after the beating the injured surface is set on fire, and about a week later the bark, if it has not fallen off spontaneously, is removed. The juice now begins to exude freely from the exposed wood, which the natives cover with rags. The latter, when saturated, are boiled in water in large jars, and the liquid allowed to stand, whereupon the water rises to the top, and is poured off, leaving the balsam, which is put into calabashes or bladders. Seven to ten days later a second flow of balsam occurs, and is secured as before. Subsequently the exposed parts are scraped or otherwise wounded, and a third balsam is obtained. These three grades of balsam are said to be known respectively as *Tagauzonte, balsamo de trapo, balsamo de contrapique.* The balsam is then taken for sale to the neighboring towns, where it is purified by subsidence and straining and put into jars or metallic drums for exportation. The destroyed bark is said to renew itself in two years, so that by care a tree can be worked for a long time; two pounds is stated to be the average yearly yield.

It is exported to the United States from San Julian, San Salvador, usually in tin canisters, and shows a whitish scum on the surface with more or less deposit which may be dissolved with the aid of heat.

A substance called *white balsam* (*Bálsamo blanco*) is procured from the fruit. This has been confounded with the balsam of Tolu, but is wholly distinct. It is of a semi-fluid or soft-fluid consistence, somewhat granular, and, on standing, separates into a white, resinous crystalline deposit, and a superior, transulcent more fluid portion. The odor, though quite distinct from that of the balsams of Tolu and Peru, is not disagreeable. Stenhouse in 1850 obtained from it a crystallizable resin, which he denominated *myroxocarpin.* (*P. J.*, x, 290.) Tschirch (*Harze und Harzbehälter,* 1900, p. 166) gives the compound the name *myroxoresene,* and the formula, $C_7H_{10}O$. Another substance obtained from the same tree, and much used in Central America, is a tincture of the fruit made by digesting it in rum. It is called *balsamito* by the inhabitants, and is used by them both internally and externally. Neither this nor the white balsam reaches the markets of this country.

Besides the official species, there are several allied trees which furnish products possessing more or less similar properties. The *M. peruiferum* L. fil. yields an oleoresin sometimes known as *Brazilian balsam.* It resembles Peru balsam but is harder and redder in color. A balsam is also derived from the *M. punctatum* Klotzsch. This tree is by some considered as identical with the *M. Toluiferum* which yields the Tolu balsam. The bark of this species has been used in Paraguay under the name of *quinoquino* as a remedy for wounds and ulcers.

From the pods of the related *Myrospermum frutescens* Jacq. which grows in Trinidad is prepared a tincture used as a lotion in rheumatic pains, and also from the incisions in the stem a balsam very similar to that of Tolu balsam. In bulk it is of a dark brown color, but in thin layers it is dark red. Its odor is smoky, feebly fragrant; its taste slightly pungent, leaving a choking, disagreeable, persistent feeling. It is entirely soluble in ether and in rectified spirits. It also mixes with castor oil in all proportions, and forms with carbon disulphide a clear, light brown solution with residue, also a deposit, in its chloroform solution, which becomes a powdery precipitate upon standing. At 17° C. its specific gravity is 1.031. Its general constitution is very similar to that of balsam of Peru, containing volatile oil, myroxylin, cinnamic and tannic acids, and resin. It is especially to be distinguished from Peru balsam by its behavior with sulphuric acid. When Peru balsam is treated with sulphuric acid, and cold water poured upon it, a beautiful violet color is imparted to the surface, and the whole mass has a bright shade. The same procedure yields with the oleo-balsam a gray mass. For further information, see *P. J.*, xv, 771.

Description and Physical Properties.—"A dark brown, viscid liquid, transparent, and appearing reddish-brown in thin layers. It has an agreeable, vanilla-like odor, and a bitter, acrid taste, with a persistent after-taste, and is free from stringiness or stickiness. It does not harden on exposure to air. The Balsam is nearly insoluble in water, but is soluble in alcohol, chloroform, and glacial acetic acid, with not more than an opalescence. It is only partly soluble in ether and in petroleum benzin.

"Specific gravity: 1.130 to 1.160 at 25° C. Water becomes acid to litmus paper when agitated with the Balsam. One Gm. of the Balsam forms a clear solution when shaken with a solution of 3 Gm. of chloral hydrate in 2 cc. of distilled water (*fixed oils*). Shake about 1 Gm. of the Balsam with 5 cc. of purified petroleum benzin, and warm the mixture on a water bath for ten minutes, adding a sufficient quantity of the solvent to replace the loss by evaporation. On evaporating 2 cc. of the benzin solution, no odor of oil of turpentine is noticeable (*turpentine*). Balsam of Peru does not show the presence of *rosin.* Dissolve about 1 Gm. of the Balsam, accurately weighed, in 100 cc. of neutral alcohol, add 1 cc. of phenolphthalein T.S., and titrate the solution with half-normal sodium hydroxide: the acid number thus obtained is not less than 56 and not more than 84. Mix about 3 Gm. of the Balsam, accurately weighed, with 30 cc. of sodium hydroxide T.S. in a separator, shake the mixture for a few minutes with 60 cc. of ether, and allow to stand until complete separation into two layers has taken place. Draw off the lower, aqueous layer and quickly filter the ethereal layer into a flask. Transfer 50 cc. of the ether filtrate (representing five-sixths of the weight of the Balsam taken) to a tared, conical flask, evaporate the ether, and dry the residue at 100° C. for thirty minutes. The weight of the residue of cinnamein so obtained corresponds to not less than 50 per cent. and not more than 60 per cent. of the weight of the Balsam represented by the 50 cc. of ethereal solution taken. Dissolve this residue in 25 cc. of alcohol, add 25 cc. of half-normal alcoholic potassium hydroxide, and heat the mixture carefully on a water bath for one-half hour, in a flask provided with a reflux condenser. Then add 1 cc. of phenolphthalein T.S., and titrate the excess of alkali with half-normal hydrochloric acid. The amount of half-normal alcoholic potassium hydroxide consumed corresponds to a saponification value for the cinnamein of not less than 235 and not more than 238." *U. S.*

"A viscid liquid, in bulk nearly black but in thin layers deep orange-brown or reddish-brown and transparent. Agreeable balsamic odor; taste acrid, leaving when swallowed a burning sensation in the throat. Insoluble in *water;* soluble in *chloroform.* 1 volume is soluble in 1 volume of *alcohol* (90 per cent.), but on the further addition of 2 or more volumes of the *alcohol* the mixture becomes turbid. Specific gravity between 1.140 and 1.158. Does not diminish in volume when shaken with an equal bulk of *water* (absence of ethylic alcohol). When tested by the following method it yields not less than 57 per cent. of cinnamein, the saponification value of which is not less than 235:—Dissolve 1 gramme of the Balsam in 30 millilitres of *ether* and shake in a separating funnel with two successive quantities of 20 and 10 millilitres of *N/2 solution of sodium hydroxide.* Separate the alkaline solution, mix and shake with 10 millilitres of *ether.* Draw off and reject the alkaline solution. Add the second ethereal solution to that previously obtained. Wash the mixed ethereal solution with two successive quantities of 5 millilitres of *water.* Transfer the ethereal solution thus washed to a tared wide-mouthed flask, evaporate at a gentle heat until the odor of ether has disappeared, add 1 millilitre of *absolute alcohol,* dry at 100° C. for half an hour, and weigh. The weight of the cinnamein thus obtained is not less than 0.57 gramme. To this residue add 20 millilitres of *N/2 alcoholic solution of potassium hydroxide* and 20 millilitres of *alcohol* (90 per cent.). Attach a reflux condenser, boil for half an hour, and tirate back with *N/2 solution of sulphuric acid, solution of phenolphthalein* being used as indicator. Each gramme of the residue thus treated requires not less than 8.4 millilitres of the alkaline solution for complete saponification (corresponding to a saponification value of not less than 235)." *Br.*

Constituents.—Balsam of Peru is a very complex mixture, and the composition is doubtless somewhat variable. Parry (*Chemistry of Essential Oils and Artificial Perfumes,* 1919) states that the principal constituents are *benzyl cinnamate,* $C_9H_2O_2.C_7H_7$ (*cinnamein*), *benzyl benzoate, benzyl alcohol, cinnamyl cinnamate* (*styracin*) and esters of an alcohol called *peruresinotannol.*

Thoms discovered a constituent called by him *peruviol* ($C_{13}H_{22}O$), which Parry believes to be identical with *nerolidol.* Tschirch states that in the sample of Peru balsam investigated by him benzyl benzoate was the main constituent, but small amounts of benzyl cinnamate were also present, and he considers that the relative proportions of the two esters may vary greatly in different samples of the balsam. The odor of the balsam Tschirch considers to be due to the *peruviol.*

The volatile oil from Balsam of Peru, according to Parry, has the following characteristics: Sp. gr. 1.10 to 1.125; optical rotation, +0 to +3; refractive index, 1.5710 to 1.5800; acid number, 25 to 48; ester number, 200 to 254. This oil is said to contain free benzoic and cinnamic acids, benzyl cinnamate, and benzyl benzoate, farnesol, dihydrobenzoic acid, and vanillin. The resinous constituent of Peru balsam, which is precipitated by hydrochloric acid from the alkaline solution of the balsam, was found by Tschirch to be the peruresinotannol referred to above, combined with cinnamic acid.

Formerly Peru balsam was much adulterated with castor oil, copaiba, turpentine, gurjun balsam, etc., but during recent years the rigid inspection has excluded most of the grossly adulterated samples from importation. Dodge and Sherndal (*J. A. Ph. A.,* 1915, p. 1222) assert that the assay for peruviol is the most reliable means for determining the authenticity of the balsam and give a method therefore. Heiduschka and Rheinberger (*Ph. Centralh.,* 220) give a method for determining the bromine value and state that a pure balsam shows a value of 17 while the adulterated samples show considerably higher values.

A synthetic substitute known as *synthetic balsam of Peru,* or *Perugen,* made by mixing benzyl benzoate with storax, benzoic and Tolu balsams so closely resembles the genuine that Enz (1913) states that the only constants useful for its detection are the acid number, iodine number, isolated cinnamein nitric acid reaction, and behavior in contact with benzin; the other pharmacopœial constants are of no value. Cæsar and Soretz state that the characteristic odor and taste of the natural balsam are absent in the substitute.

A color test to distinguish true Peru balsam from the factitious variety is as follows: One drop of Peru balsam is shaken with 5 cc. of petroleum benzin, and to 2.5 cc. of this liquid 5 cc. of ether is added. Sulphuric acid is then added, drop by drop, until from 10 to 15 drops have been added. Genuine Peru balsam gives beautiful violet to cornflower blue color in the lower layer, while the artificial products give either no color or very different shades.

For additional tests of purity of Peru balsam, see van Itallie, *Ph. Wb.,* 1920, lvii, 1383; also *Proc. A. Ph. A.,* 1894, 903; and 1895, 866; *D. C.,* 1898, 60.

Grote's test consists in shaking 3 drops of balsam with 2 cc. of official ammonia water; if, after standing, the mixture solidifies, rosin or other adulterant is present; benzoin, storax, and certain other substances cannot be detected by this test. (*A. J. P.,* 1881, 302, 361.)

Cocking and Kettle (*P. J.,* 1918, p. 90) propose an assay for the valuation of Peru balsam and give figures obtained upon various samples.

Uses.—Balsam of Peru is useful internally as a stimulating expectorant in *asthma* and *chronic bronchitis,* especially when of tuberculous origin. Although not so agreeable as balsam of Tolu it is much more active. Externally it affords a valuable stimulating dressing in indolent *ulcers* and local *tuberculosis* of the skin, bone, larynx, etc. It has also been highly lauded by Malannik (*M. M. W.,* 1912) as a first dressing for military *wounds.* He asserts that it is not only bactericidal of itself but that it stimulates the local resistance of the tissues and and that it exercises a valuable protective action. Extensive erythema has followed its local application. (Hazen, *J. A. M. A.,* 1910, liv.) Internally it is best administered in emulsion.

Dose, five to fifteen minims (0.3–1 cc.).

Off. Prep.—Mistura Oleo-balsamica, *N. F.;* Solutio Mastiches Chloroformica Compositura, *N. F.*

BAPTISIA. N. F.

BAPTISIA Baptis. [Wild Indigo]

"Baptisia is the dried root of *Baptisia tinctoria* (Linné) R. Brown (Fam. *Leguminosæ*). Baptisia contains not more than 10 per cent. of its stem bases, overground parts or foreign organic matter." *N. F.*

Wild Indigo; *N. F.* Indigo sauvage, *Fr.;* Baptisie, *G.*

This is an indigenous, perennial herb, abundant throughout the Eastern United States, in woods and dry, barren uplands. Its leaves are trifoliate with cuneate-obovate leaflets. Its inflorescence is a short raceme of yellow flowers. Its fruit is a subcylindric, many seeded legume.

Description and Physical Properties.—"*Unground Baptisia.*—Fleshy, 0.5 to 4 cm. thick, usually cut into elongated cylindrical pieces, the crown 5 to 8 cm. thick, more or less warty and marked by stem scars; outer surface dark brown; usually longitudinally wrinkled, the thicker pieces covered with a soft friable corky layer, bearing few branching rootlets; fracture tough the fractured surface whitish; bark section radially striate, wood section inconspicuously radiate, porous. Nearly odorless, the bark bitter and acrid, the wood nearly tasteless.

"*Powdered Baptisia.*—Light grayish; starch grains numerous, rounded, simple or 2- to 4-compound, up to 0.016 mm. in diameter, the larger grains sometimes with a cleft through the center; tracheæ up to 0.090 mm. in diameter and with bordered pores; numerous fibers, long, thick-walled, non-porous, more or less lignified and up to 0.024 mm. in width; fragments of medullary ray tissue composed of cell with lignified walls and numerous simple pores; groups of parenchyma, many of the cells filled with starch; few epidermal and cork cells with brownish walls." *N. F.*

Baptisia contains, according to Gorter (*A. Pharm.*, 1897, ccxxxv, p. 321), a non-toxic glucoside *baptisin,* and an alkaloid *baptitoxine;* the latter appears to be identical with cytisine (see *Cytisus,* Part II). There is present also a blue dye which has been used as a substitute for indigo, to which it is, however, greatly inferior.

Uses.—Baptisia is used both locally and internally in the treatment of various septic conditions. Thus, it has been recommended as a gargle in ulcerative *pharyngitis,* as an application to foul *ulcers* and internally in the treatment of various infectious *fevers.* Its value, however, is open to question. In over-doses it acts as an emetic and cathartic.

Dose, from five to twenty grains (0.3–1.3 Gm.).

Off. Prep.—Dentifricium, *N. F.;* Fluidextractum Baptisiæ, *N. F.*

BARBITALUM. U. S. (Br.)

BARBITAL Barbital. [Diethylbarbituric Acid, Barbitone]

"Diethylmalonylurea [$CO(HN.CO)_2C(C_2H_5)_2$]." *U. S.*

"Barbitone, $C_8H_{12}N_2O_3$, may be obtained by the interaction of the diethyl ester of malonic acid, and carbamide." *Br.*

Barbitonum, *Br.;* Acidum Diaethyl-barbituricum, Diethyl Malonyl-urea, Malonurea; Veronal; Veronalum, *Fr. Cod.;* Malourea.

This compound is chemically related to urea. It is prepared by the condensation of diethylmalonic ester and urea in the presence of sodium. The sodium salt is first produced and the acid is then set free by the hydrochloric acid. In another method diethyl cyano-acetic ester is heated with sodium and urea in absolute alcohol solution. This produces iminodiethylmalonylurea which is heated with hydrochloric acid in weak solution which hydrolizes it to barbitone. In a third method diethyl malonyl chloride and urea are heated together to form barbitone by direct combination, hydrochloric acid being evolved.

Description and Physical Properties.—"Colorless or white crystals, or a white crystalline powder. It is odorless, has a slightly bitter taste, and is stable in the air. One Gm. of Barbital is soluble in 130 cc. of water, 14 cc. of alcohol, 75 cc. of chloroform, and in 35 cc. of ether, at 25° C. One Gm. is soluble in 13 cc. of boiling water. It is also soluble in acetone, and in ethyl acetate.

"Barbital melts between 187° and 190° C. A saturated aqueous solution of Barbital is acid to litmus paper. A saturated aqueous solution of Barbital yields with mercuric nitrate T.S. a white precipitate which is soluble in an excess of the reagent. When Barbital is boiled with an excess of sodium carbonate T.S. for thirty minutes, or when fused with sodium hydroxide, it is decomposed with the evolution of ammonia.

"The ash from 0.5 Gm. is negligible. A solution of 0.2 Gm. of Barbital in 2 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Another portion of 0.2 Gm. of Barbital is not colored by shaking with 2 cc. of nitric acid." *U. S.*

It is described by the British Pharmacopœia as: "A white crystalline powder. Inodorous; taste faintly bitter. Slightly soluble in cold *water,* the solution being neutral to *litmus;* more soluble in hot *water,* and in *alcohol* (90 per cent.); freely soluble in aqueous solutions of the alkalies. Melting point 191° C. When fused with a caustic alkali, ammonia is evolved; and, when the cooled residue is dissolved in *water* and the solution acidified with *diluted sulphuric acid,* carbon dioxide is liberated, and a characteristic odor resembling that of fatty acids is developed. A few drops of *solution of mercury nitrate* added to 25 millilitres of a saturated aqueous solution acidified with *nitric acid,* produces a gelatinous precipitate. No appreciable ash." *Br.*

Barbital may be detected in the urine of persons taking it, by treating the urine with lead acetate solution, filtering and shaking out with ethyl acetate.

Barbitone unites with various bases to form salts, many of which are soluble. One of these, the sodium salt, is official.

Uses.—Barbital is absorbed with moderate rapidity through the intestinal mucous membrane, its effects generally being manifest in about thirty minutes after its ingestion. It is eliminated solely through the kidneys, although Bachem (*A. E. P. P.*, 1910, lxiii, p. 228) believes that a considerable proportion is destroyed in the system. After small doses it is practically all eliminated within twelve hours, but when large quantities have been taken it may be retained in the system for long periods of time and when used repeatedly tends to accumulate in the body. In small doses it produces in the lower animals usually no symptoms but sleep, although after even moderate quantities the blood pressure may be reduced. In large doses it causes decided fall in the blood pressure through dilatation of the abdominal blood vessels, muscular weakness in the posterior extremities without loss of reflex, muscular fibrillation which may be sufficiently violent to simulate convulsions, diminution of respiration, and fall of bodily temperature. After very large poisonous doses there is loss of pain perception and diminution of reflex. (Roemer, *J. P. Ex. T.*, 1911, vi, p. 241.)

Barbital is a powerful somnifacient useful in many forms of *agrypnia* when not due to pain. Its effects are generally manifest in from a half to one hour and last over the greater portion of the night. Generally the patients awake without showing any symptoms of veronal action, but House (*T. G.*, May, 1913) reports that occasionally patients complain of slight vertigo in the morning, which he attributes to the reduction in blood pressure.

Diethylbarbituric acid has also been used as a general sedative in *hysteria, chorea,* and especially in *sea-sickness.* Hildebrandt (*Zeitschrift für ärztliche Fortbildung,* 1913, No. 12, p. 366) recommends it for the relief of *night sweats* in pulmonary tuberculosis.

While in the proper doses barbital is usually a satisfactory somnifacient it is by no means the harmless drug that it has been sometimes considered. A considerable number of fatal cases of poisoning have been reported (see *P. J.*, 1911, lxxxvi, p. 235, and Boenheim, *Med. Klin.*, 1921, xvii, p. 1263). While in most of these cases the dose has been very large—more than 5 Gm. (75 grains), Wilcox (*B. M. J.*, 1913, ii, p. 663) states that fifteen grains has proven fatal. On the other hand, according to Gautier (*R. M. S. R.*, 1918, xxxviii, 641), recoveries are known after doses of 10 Gm. There have also been reported a number of cases of veronal addiction.

There are apparently a considerable number of people who have marked idiosyncrasy against the drug, in whom even doses as small as 0.3 Gm. (5 grains) produce violent eruptions of the skin, usually scarlatinaform in character, often accompanied with considerable fever and followed by desquamation.

In ordinary cases of *barbital poisoning* the most striking symptom is profoundly stuporous sleep from which, in severe cases, no external excitation can arouse the patient. The pupils are neither dilated nor contracted, the respiration is usualy quiet and, although somewhat slower than normal, not much slower than is often seen in natural sleep. In many cases there is marked fever. There is frequently also a manifest tendency towards pneumonia or pulmonary edema. The treatment, after washing out of the stomach, is purely symptomatic.

The *dose* is from five to ten grains (0.32–0.65 Gm.), stirred up in water or enclosed in a gelatin capsule. It should not be given in pill form.

BARBITALUM SOLUBILE. U. S.

SOLUBLE BARBITAL Barbital Sol.

BARBITAL SODIUM. [Sodium Diethylbarbiturate, [Sodium Diethylmalonylurea Barbitone Sodium]

"Soluble Barbital, when dried to constant weight at 100° C., contains not less than 98.5 per cent. of $CO(NaN.CO)(HN.CO)C(C_2H_5)_2$." *U. S.*

Veronal Sodium; Veronal Soluble; Medinal; Sodii Diæthyl barbituras; Barbital Sodium.

This compound is the mono-sodium salt of diethyl-barbituric acid and represents 89.3 per cent. of barbital. Its chief advantage is its solubility in water.

Barbital sodium is officially described as follows:

Description and Physical Properties.—"A white powder. It is odorless, has a bitter taste, and is stable in the air. One Gm. of Soluble Barbital is soluble in about 5 cc. of water at 25° C., and in 2.5 cc. of boiling water. It is slightly soluble in alcohol and is insoluble in ether.

The barbital obtained in the assay melts between 187° and 190° C., and responds to the other identity tests given under *Barbitalum.* An aqueous solution of Soluble Barbital is alkaline to litmus paper. The addition of diluted hydrochloric or sulphuric acid to an aqueous solution of the salt (1 in 20) produces a precipitate of barbital.

"A solution of 0.2 Gm. of the salt in 2 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Ten cc. portions of an aqueous solution of Soluble Barbital (1 in 100) acidulated with a few drops of nitric acid yield no opalescence at once on the addition of a few drops of silver nitrate T.S. (*chloride*), and no turbidity within one minute on the addition of 1 cc. of barium chloride T.S. (*sulphate*). An aqueous solution of the salt meets the requirements of the test for *heavy metals.* When dried to constant weight at 100° C., it loses not more than 1 per cent. (*water*). Shake 0.5 Gm. of Soluble Barbital with 20 cc. of dehydrated ether for ten minutes, filter, evaporate the ether, and dry at 100° C.: the weight of the residue does not exceed 0.003 Gm. (*uncombined barbital*).

"**Assay**—Dissolve about 1 Gm. of Soluble Barbital, previously dried at 100° C. and accurately weighed, in 10 cc. of distilled water in a separator, add to the solution 15 cc. of diluted hydrochloric acid, and extract the liberated barbital by shaking successively with eight portions of 25 cc. each of ether. Evaporate the combined ether solutions at as low a temperature as possible, and dry at 100° C. The weight of the barbital so obtained is not less than 88 per cent. and not more than 90 per cent. of the dried Soluble Barbital. About 0.2 Gm. of the barbital, obtained in the assay, leaves a negligible residue upon ignition." *U. S.*

Because of its freer solubility, this drug acts more promptly than barbital. It may be used for the same purposes as veronal. Munk (*Med. Klin.*, iv, p. 1834) has also employed it hypodermically in the form of a ten per cent. solution. The injections are somewhat painful, because of the large volume of the injection.

Dose, from five to fifteen grains (0.3–1.0 Gm.).

BARII SULPHAS. U. S.

BARIUM SULPHATE

"Barium Sulphate [$BaSO_4$], freed from soluble barium salts. *Caution.—In prescribing Barium Sulphate the title should never be abbreviated, to avoid confusion with the poisonous barium sulphide or sulphite.*" *U. S.*

Sulphate of Barytes, Synthetic Barytes, Precipitated Barium Sulphate, Artificial Heavy Spar, Permanent White, Baroselenite, Terra Alba, Constant White, Terra Ponderosa, Baric Sulphate, New White, Mineral White, Snow White; Baryte Sulfate, Baryte Sulphurique, Blanc Fixé, *Fr.*; Barytspath Schwefelsaurer Baryt, *G.*; Baryum Sulfuricum.

A native barium sulphate, known as *barytes* or *heavy spar,* is the most abundant of the natural salts of barium and is mined extensively in the United States. The medicinal salt, however, is usually produced by precipitation in order to provide a purer article. The native variety of barium sulphate is a heavy, lamellar, brittle mineral, usually translucent, sometimes transparent or even opaque; color white or pale pink. It sometimes occurs in flat rhombic prisms. Artificial barium sulphate, obtained as a by-product in many chemical manufactures, is much used in the arts as a pigment, and as a weighting and filling material in paper manufacturing, etc. When prepared with especial care and subsequently purified it forms one of the most insoluble and inert substances known to chemistry, and is especially valuable in the outlining of the alimentary tract for X-ray work.

Description and Physical Properties.—"A fine, white, odorless, tasteless and bulky powder, free from grittiness. Barium Sulphate is insoluble in water, in organic solvents, and in aqueous solution of acids and alkalies.

"Mix 0.5 Gm. of Barium Sulphate with 2 Gm. each of anhydrous sodium carbonate and anhydrous potassium carbonate, heat the mixture in a crucible until fusion is complete, treat the resulting fused mass with hot water, and filter. Acidulate a portion of the filtrate with hydrochloric acid, and add 1 cc. of barium chloride T.S.: a white precipitate forms. Dissolve in acetic acid a portion of the well-washed precipitate, obtained in the preceding test: the solution responds to the reactions for barium.

"Boil 10 Gm. of Barium Sulphate with a mixture of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water for ten minutes, and add sufficient distilled water to restore the original volume. During boiling there should be no evolution of hydrogen sulphide, recognizable by the darkening of lead acetate paper exposed to the vapor (*sulphide*). Cool the mixture, and filter through paper which has been previously washed with a solution of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water, returning the first portions if necessary until a perfectly clear filtrate is obtained. Evaporate 50 cc. of the filtrate to dryness on a water bath, add two drops of hydrochloric acid and 10 cc. of hot distilled water. Filter through acid-washed paper, wash with 10 cc. of hot distilled water, and evaporate the combined filtrate and washings to dryness in a tared dish on a water bath. The residue, when dried to constant weight at from 100° to 110° C., should not be fine, white, odorles, tasteless and bulky powder, more than 0.3 per cent. (*limit of acid-soluble substances*). Treat this residue with 10 cc. of distilled water, filter the solution through a filter previously washed with a mixture of 10 cc. of diluted hydrochloric acid and 90 cc. of distilled water, and add 0.5 cc. of diluted sulphuric acid: no turbidity should develop within one-half hour (*soluble barium salts*). Boil 1 Gm. of Barium Sulphate with a mixture of 3 cc. of nitric acid and 5 cc. of distilled water during five minutes. Filter, and add to the warm filtrate an equal volume of ammonium molybdate T.S.: no yellow precipitate is formed (*phosphate*). Digest 1 Gm. of Barium Sulphate with 20 cc. of distilled water during five minutes: the latter remains neutral to litmus paper (*free acid or alkali*). Boil 5 Gm. of Barium Sulphate with 50 cc. of diluted acetic acid, and filter while hot: the filtrate meets the requirements of the test for *heavy metals.* Triturate 2 Gm. of Barium Sulphate with 5 cc. of concentrated hydrochloric acid, and add 10 cc. of a freshly made, saturated solution of stannous chloride: no dark coloration occurs with one-half hour (*arsenic*)." *U. S.*

Uses.—Barium sulphate is used in medicine solely because of its opacity to the X-ray. Because of this property and its insolubility it is of great value in making roentgenograms of internal cavities, especially the alimentary canal. The advantages claimed for it over the bismuth salts, which are used for similar purposes, are its relative inexpensiveness and that slightly smaller quantities are required. For X-ray examination of the alimentary canal it is usually given suspended in water by some mucilaginous substance. The following formula for this purpose has been suggested: barium sulphate 50 Gm., corn flour 5 Gm., sugar 5 Gm., cocoa 7 Gm., water 150 cc. (*A. J. P.*, 1918, xc, 284).

Toxicology.—It should be remembered that the soluble barium salts are actively poisonous. The safety of barium sulphate in such large doses is due to its insolubility. Karaoglanow (*Pharm. Weekblad.*, 1918, lv, 47) has found that from 2.5 milligrammes to 4.3 milligrammes of barium sulphate dissolve in a liter of water, according to the degree of fineness of the powder. The same author has also shown that the solubility is decreased by the presence of the sulphuric ion and increased by nitric or hydrochloric acid. The exact lethal dose of barium is not definitely known but Aloy and Kournet (*J. P. C.*, 1918, xvii, p. 76) have found that the barium chloride is fatal to dogs in doses by mouth of from 0.025 to 0.09 Gm. per kilo of body weight which would correspond to approximately 27 to 98 gr. for the ordinary adult man (1.7 to 6.3 Gm.). A number of fatal cases of poisoning by other salts, especially the sulphide, of barium, which have been mistakenly used for X-ray work have been recorded. In a case reported by Bensaude and Antoine (*B. Hôp. Par.*, 1919, xliii, 369), the patient was seized immediately after drinking the suspension of barium and was dead in 10 minutes. In other cases the appearance of symptoms has been delayed as much as an hour and death until the following day. The characteristic symptoms are; burning pain in the stomach, nausea and vomiting, the latter often bilious followed by diarrhea with violent abdominal cramps. Post-mortem examination shows intense congestion of the alimentary canal, with sometimes minute hemorrhages, also congestion of the liver and kidney.

The proper *treatment* consists in the immediate administration of large quantities of magnesium sulphate followed by repeated washings of the stomach. Unfortunately, however, many of these cases occur where medical attention is not to be had immediately and the progress of the poisoning is so rapid that the patient is dead before proper aid can reach him.

In view of the considerable number of fatalities that have been recorded from the substitution of barium sulphide for the sulphate we would urge—upon the medical profession: 1. That no abbreviation be used in prescribing the drug; the official name should be written out in full, *Barii Sulphatis.* 2. The addition of sulphuric acid to the suspension which would tend to increase the insolubility of the drug—and on the pharmacist: 3. That in labelling all stock bottles he avoid the use of the abbreviation so common as Bar. Sulph.; like the physician's prescription his label should bear the official name written out in full. 4. That he never dispense large amounts of barium sulphide without definite information of the purpose for which it is to be used. 5. If he carries barium sulphide in stock it be kept on the poison shelf. 6. That barium sulphide, which may be called for as a depilatory, be labeled "Poison."

BELÆ FRUCTUS. Br.

BAEL FRUIT

"Bael Fruit is the fresh half-ripe fruit of Ægle Marmelos, *Correa.*" *Br.*

Fructus Baël, Béla; Bael fruit, Indian Bael, Bhel, Bengal Quince; Marmelos de Benguala, Cirifole, Beli; Indische Quitten, Marmelosbeeren, Marmelosfrüchte, *G.*

The so-called *Bengal quince* is a rather large tree (Fam. *Rutaceæ*), extensively cultivated in India, with an erect stem, few and irregular branches, an ash-colored bark, strong, very sharp, axillary thorns, single or in pairs, trifoliate leaves and large white flowers. The fruit is a berry of delicious flavor, of about the size of a large orange, with a hard, smooth, greenish shell, and from ten to fifteen loculi containing besides the compressed, wooly seeds a large quantity of exceedingly tenacious mucilage, which when dried is hard and transparent. "Fruit about 7 or 8 cm. in diameter, globular, ovoid or pyriform, grayish or yellowish-brown. Outer surface hard, nearly smooth. Rind about three millilitres in diameter, and adherent to a pale-reddish juicy pulp in which are ten to fifteen cells, each containing several woolly seeds. Faint aromatic odor; taste mucilaginous, acidulous, and slightly astringent." *Br.* The mucilage about the seeds is applied to various purposes in the arts, on account of its viscid properties. The rind is used in dyeing. The flowers are deemed refrigerant by the native physicians. The fresh leaves yield by expression a bitterish and somewhat pungent juice, which, diluted with water, is occasionally used in the early stage of catarrhal and other *fevers.* The bark of the stem and root is thought to possess febrifuge properties.

The difficulty of obtaining bael in England is said to have led to the substitution for it of *mangosteen,* the fruit of *Garcinia Mangostana* L. (Fam. *Guttiferæ*). This is in irregular fragments of the rind, without adhering pulp. The pieces are convex, three or four lines or more in thickness, externally covered with a smooth, deep reddish-brown, easily separable coating, and internally pale reddish-brown or reddish-yellow, smooth, with projecting vertical lines. Another substitute which has appeared is the wood apple, *Feronia Elephantum* Correa (Fam. *Rutaceæ*).

The most important constituent of bael fruit appears to be its mucilage. It also contains pectin, sugar and traces of tannic acid and of an essential oil (see Badakow, *Ap. Ztg.*, 1894, p. 773).

Uses.—Bael fruit has been used in India in the treatment of *diarrhea* and *dysentery* for many years. It is also asserted to have laxative properties. Whether it has any real therapeutic activity is, at present, very doubtful. The *decoction,* two ounces of dried fruit in a pint of water boiled down to four fluidounces, is used in *doses* of one to two fluidounces (30–60 cc.) every two to six hours.

Off. Prep.—Extractum Belæ Liquidum, *Br.*

BELLADONNÆ FOLIA. U. S., Br.

BELLADONNA LEAVES Bellad. Fol. [Belladonnæ folium P. I.]

"Belladonna Leaves consist of the dried leaves and tops of *Atropa Belladonna* Linné (Fam. *Solanaceæ*). Belladonna Leaves yield not less than 0.3 per cent. of the alkaloids of Belladonna Leaves, and contain not more than 3 per cent. of their stems over 10 mm. in diameter, and yield not more than 3 per cent. of acid-insoluble ash." *U. S.*

"Belladonna Leaves are the leaves of Atropa Belladonna, *Linn.*, collected when the plant is in flower, and dried." *Br.*

BELLADONNÆ RADIX. U. S., Br.

BELLADONNA ROOT Bellad. Rad.

"Belladonna Root is the dried root of *Atropa Belladonna* Linné (Fam. *Solanaceæ*). Belladonna Root yields not less than 0.45 per cent. of the total alkaloids of Belladonna Root, and contains not more than 10 per cent. of its stem bases and woody crowns, and not more than 2 per cent. of other foreign organic matter, and yields not more than 4 per cent. of acid-insoluble ash." *U. S.* "Belladonna Root is the root of Atropa Belladonna, *Linn.*, collected in the autumn and dried." *Br.*

Racine de Belladone, Belladone, *Fr.*; Gemeine Tollkirsche, Wolfskirschen-Wurzel, *G.*; Radice di Belladonna, *It.*; Raiz de Belladona, Belladama, *Sp.*

The belladonna, or *deadly night-shade* (*Atropa Belladonna*) is an herbaceous perennial, with a fleshy, creeping root, from which rise several erect, round, purplish, branching stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendant, of a brownish-purple color, with solitary peduncles, rising from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately deep purple and containing, in two loculi, numerous seeds and a sweetish violet-colored juice. The calyx adheres to the base of the fruit.

The plant is a native of Central and Southern Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. It grows vigorously under cultivation in England, France and the United States. During the past few years there has been very great interest in the cultivation of belladonna in the United States. The results of all experiments show that a high grade of belladonna can be grown in this country. (Consult Borneman, *A. J. P.*, 1909, p. 1; Miller, *A. J. P.*, 1913, p. 291; Carr, *Ibid.*, 1913, p. 487; Sievers, *A. J. P.*, 1914, p. 483, also 1917, lxxxix, 203; Newcomb, *A. J. P.*, 1915, p. 1; Kock, *J. A. Ph. A.*, 1919, p. 390.) Plants cultivated in California are very rich in active constituents. The yield per acre of stems and leaves is somewhat less than one ton. The experiments in California seemed to show that the alkaloidal contents of belladonna stems is equal to that of the leaves, ranging from 0.51 to 0.82 per cent. of total alkaloids. (*Pacific Pharmacist*, 1909; 1910, p. 295.) Belladonna leaves grown in the shade are uniformly larger, though somewhat thinner. It is quite likely that the percentage of alkaloids can be increased through selection. (*A. J. P.*, 1914, p. 483, and 1917, lxxxix, 254.) All parts of it are active. The leaves and roots are directed by the United States and British Pharmacopœias, the latter including the branches, which, if young, are probably not less efficient. The leaves should be collected in June or July, when the plant is in flower, the roots in the autumn or early in the spring, and from plants three to four years old. Leaves which have been kept long should not be used, as they undergo change through absorption of atmospheric moisture, emitting ammonia, and probably losing a portion of their active nitrogenous matter. Sievers (*A. J. P.*, 1916, lxxxviii, 193) has found that no relation exists between the appearance of the leaves and the percentage of alkaloid. He found the amount of alkaloid in leaves of cultivated plants varied from 0.30 to 0.76 per cent. Specimens which contain much stem or are musty should always be rejected, as weak in active principle. Holmes has found in the English market the root of *Medicago sativa* used as an adulterant. (*P. J.*, 1882.)

Both herb and root drugs are obtained for the most part from plants cultivated in the United States, Central Europe and England.

Description and Physical Properties.—"*Unground Belladonna Leaves.*—Usually matted together, crumpled or broken; leaves mostly light green, from 5 to 20 cm. in length, and from 4 to 12 cm. in width, broadly ovate, apex acute, margin entire, narrowed into the petiole, with few hairs, the latter more abundant along the veins, and numerous whitish dots (crystal cells) visible with a lens; stems more or less hollow and flattened, finely hairy when young; flowers with campanulate corolla, yellowish-purple, becoming faded, usually subtended by the calyx; fruits nearly globular, green to brown or purplish-black with numerous, flattened somewhat reniform seeds, up to 2 mm. in width; odor slight, somewhat tobacco-like when moistened; taste somewhat bitter and acrid.

"*Structure.*—Leaves of simple structure; epidermis with wavy vertical walls and distinctly striated cuticle; stomata more numerous on the lower surface and usually with 3 neighboring cells; non-glandular hairs 2- to 6-celled; glandular hairs, short-stalked with 1- to many-celled heads; crystal cells large, filled with microcrystalline calcium oxalate, numerous in the mesophyll. Stem with long, thin-walled, slightly lignified bast, crystal cells and a few hairs. Pollen grains narrow ellipsoidal, with three meridional furrows. Seed epidermis with convolute, thickened cell walls.

"*Powdered Belladonna Leaves.*—Green to brownish-green in color. The following are among the elements of identification: the separate microcrystals, the dark gray crystal cells, the cuticular striping of the epidermal cells, the tracheæ with bordered pores, the bast- and wood-fibers of the stem, and, rarely, the hairs and pollen grains.

"In Belladonna Leaves rosette aggregates of calcium oxalate are absent (*stramonium leaves*). In Belladonna Leaves raphides are absent (*phytolacca leaves*).

"**Assay.**—Proceed by Type Process B, using 10 Gm. of Belladonna Leaves in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloid from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Belladonna Leaves (Proximate Assays)." *U. S.*

"Eight to twenty centimetres long, broadly ovate, acute, entire, glabrous or nearly so. Transverse section exhibits bi-collateral vascular bundles; mesophyll contains numerous cells filled with very minute crystals of calcium oxalate; epidermal cells of both surfaces possess a delicately striated cuticle. Yields not less than 0.30 per cent. of alkaloids when assayed as directed below." *Br.*

The roots are described as follows:

"*Unground Belladonna Root.*—Cylindrical or tapering, sparingly branched, often split longitudinally or broken transversely; from 0.5 to 4 cm. in thickness; light grayish-brown externally, nearly white internally; somewhat wrinkled longitudinally and the soft periderm frequently abraded; fracture short, mealy and emitting a puff of dust consisting chiefly of starch grains; nearly odorless when dry, but characteristic when moistened; taste sweetish, then bitterish and acrid.

"*Structure.*—Cork, a few layers of thin-walled cells; large crystal cells, filled with microcrystalline calcium oxalate, and relatively numerous in the younger roots, scattered through the abundant, starch-bearing parenchyma of the bark and wood; large porous or reticulate tracheæ in scattered groups and, in the older roots, associated with wood-fibers; cambium layer conspicuous; the medullary rays 1 to 5 cells wide.

"*Powdered Belladonna Root.*—Ash-gray to light brown; starch grains numerous, simple and compound, the single grains up to 0.030 mm. in diameter and with a distinct somewhat excentric hilum, the polarizing bands increasing in distinctness in direct ratio to the size of the grains; numerous sphenoidal microcrystals from 0.003 to 0.010 mm. in length; fragments of tracheæ and wood-fibers few; long, thin-walled, slightly lignified bast-fibers from belladonna stem very few. Old fibrous roots contain an excess of lignified tissue.

"**Assay.**—Proceed by Type Process B, using 10 Gm. of Belladonna Root in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloids from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Belladonna Root (Proximate Assays)." *U. S.*

"Nearly cylindrical pieces, entire or longitudinally split, usually ten to twenty millimetres in diameter, and fifteen to thirty centimetres or more in length. Externally pale greyish-brown, and finely wrinkled longitudinally. Transverse fracture short. Internally whitish and starchy. Within and mostly near to the cambium ring are numerous scattered groups of vessels and fibers which do not exhibit a prominently radiate arrangement. Most of the parenchymatous cells contain small compound starch grains; some are filled with numerous very minute, crystals of calcium oxalate. Taste slightly bitter." *Br.*

The British assay process is as follows:

"Into a small, stoppered, glass percolator provided with a glass tap and suitably plugged with cotton wool introduce 10 grammes of Belladonna Leaves in No. 60 powder and 50 millilitres of a mixture of *chloroform* 1 volume and *ether* 4 volumes. Shake; set aside for ten minutes; then add 2 millilitres of *solution of ammonia* diluted with 3 millilitres of *water,* and set aside for one hour, shaking frequently, Then allow percolation to proceed slowly, receiving the percolate in a separator containing 6 millilitres of *N/1 solution of sulphuric acid* diluted with 20 millilitres of *water.* When the liquid ceases to pass continue the percolation with a further 50 millilitres or more of the ether-chloroform mixture, added in small quantities, until the Leaves are exhausted. Shake the separator well and, after separation, draw off the acid liquid into a second separator. Repeat the extraction of the ether-chloroform solution with two successive portions, each of 10 millilitres, of the diluted acid. Make the mixed acid solutions alkaline with *solution of ammonia,* and shake out with three successive portions of 15, 15, and 5 millilitres of *chloroform.* Evaporate the mixed chloroformic solutions to dryness, dissolve the residue in 3 millilitres of *ether,* and again evaporate to dryness. Dissolve the residue in 10 millilitres of *N/20 solution of sulphuric acid,* and titrate with *N/20 solution of sodium hydroxide, tincture of cochineal* being used as indicator. Deduct the number of millilitres of the alkaline solution required from 10, multiply the difference by 0.1446; the product will be the percentage of alkaloids in the Leaves." *Br.*

For other assays of belladonna leaves and root, and comments, see Keller (*Ph. Ztg.,* 1894, 345); Moerk (*A. J. P.,* 1899, 105); LaWall and Pursell (*A. J. P.,* 1899, 394); Puckner (*Ph. Rev.,* 1902, 457); Bird (*P. J.,* 1900, 195); Kebler (*Am. Drug.,* 1902, 215); Schmidt (*Ap. Ztg.,* 1900, 13).

The usual adulterants of belladonna leaves are the leaves of *Phytolacca* and *Ailanthus* and the leaves and tops of *Solanum nigrum* and *Scopola carniolica.* Phytolacca leaves may be detected by the presence of numerous raphides as well as crystal sand. Scopola leaves and tops show characteristic barrel-shaped reticulate tracheæ as well as short calyx tubes, each having a contained pyxis. Solanum nigrum or black nightshade has ovate, wavy-toothed leaves and a white rotate corolla. For distinction between belladonna and scopola leaves see article by Kraemer. (*Proc. A. Ph. A.,* 1908, p. 819.) Guérin and Guillaume describe the anatomical difference in the leaves of belladonna, phytolacca and ailanthus. (*Bull. Soc. Pharmacol.,* 1908, p. 213.)

Belladonna root is not infrequently of inferior quality because of the presence of large quantities of the stem-bases of the plant. Reports still come in that the root is adulterated with phytolacca and replaced by 15 to 20 per cent. of scopola. Rusby has reported the presence of 25 per cent. of some inert root, apparently wild althæa, or a relative of that plant. Youngken reports the main adulterants of belladonna root as roots of *Phytolacca decandra,* unpeeled roots of *Althæa officinalis* and rhizomes of *Scopola carniolica.* Phytolacca roots possess a tough fibrous fracture and exhibit in transverse sections series of concentric circles of open collateral fibrovascular bundles; the diagnostic tracheæ have diamond-shaped bordered pores; as in the case of the leaves, raphides and crystal sand are present. Althæa roots show numerous mucilage sacs, sclerenchyma fibers, ellipsoidal starch grains and a few rosettes of calcium oxalate. Scopola rhizomes possess characteristic reticulate tracheæ.

Scopola rhizome has been largely used by manufacturers of belladonna plasters in the place of belladonna root.

Constituents.—Belladonna contains volatile bases both of an alkaloidal and a non-alkaloidal type. They are pyridines, pyrrols and diamines. It is generally recognized that the following mydriatic alkaloids are found in the solanaceous plants; *atropine, hyoscyamine, scopolamine, atroscine, apoatropine, tropacocaine, meteloidine* and *belladonine.* The first two of these, atropine and hyoscyamine, are isomeric, having the formula $C_{17}H_{23}O_3N$, and yield the same decomposition products. They differ, however, in their physical constants, especially in their relation to polarized light; whereas hyoscyamine is strongly lævo-rotatory, atropine is optically inert. Will (*B. Chem. G.,* 1888, p. 1717) has shown that hyoscyamine is readily changed into atropine and that varying proportions of the two alkaloids may be obtained from the same specimen of belladonna, according to the method of extracting from the crude drug. His conclusions have been confirmed by Gorio and Coty (*Bull. d. Sciences Pharmacol.,* 1921, xxviii, 545). The studies of the latter as well as those of Schutte (*A. Pharm.,* 1891, ccxxix, No. 7) demonstrate that atropine, if it occur at all in belladonna, is in much smaller amount than hyoscyamine. Atropine appears to be a mixture of lævo-rotatory and dextro-rotatory hyoscyamines. The dextro-hyoscyamine does not appear to occur in nature, but has been prepared artificially. Of these, atropine occurs in the *Atropa Belladonna* and in *Datura Stramonium,* hyoscyamine in these plants and also in *Hyoscyamus niger, Hyoscyamus muticus* and *Duboisia myoporoides;* scopolamine is found in *Hyoscyamus niger* and in *Scopola carniolica,* and belladonine in belladonna root alone.

For differentiation between atropine and hyoscyamine see under *Atropina.*

Apoatropine, $C_{17}H_{21}O_2N$, or *atropamine,* was discovered by Pesci in 1881 (see also Hesse, *An. Chem.,* 1893, cclxxvii, p. 290). It crystallizes in prisms and has a melting point of 60° C. It decomposes into tropine and *atropic acid,* the latter being related to tropic acid. *Belladonine* discovered by Hübschmann in 1858 is isomeric with apoatropine. According to Hesse, the latter changes into belladonine when heated with hydrochloric acid in sealed tubes. It is an uncrystallizable resinous base whose chemical individuality is questioned by some authorities.

Uses.—All parts of the belladonna plant are poisonous. It is not uncommon in countries where it grows wild, for children to pick and eat the berries, allured by their fine color and sweet taste. The symptoms of belladonna poisoning are precisely the same as those of atropine poisoning.

The conclusion of chemists that the active principle of belladonna is hyoscyamine rather than atropine, harmonizes with clinical experience because practical experience has shown that, although qualitatively indistinguishable in its action from atropine, belladonna is efficacious in doses considerably smaller than might be expected from its content of alkaloid if the latter were atropine. For description of the physiological and therapeutic properties of belladonna, see under *Atropine.*

The various preparations are much used locally. Rubbed upon the areola of the breast, it has been believed to arrest the *secretion of milk* and is frequently employed in *mastitis.*

The decoction or extract, applied to the neck of the uterus, is asserted to have hastened *tedious labor* dependent on rigidity of the os cervicis; and spasmodic *stricture of the urethra, neck of the bladder,* and *anal fissures* and *painful uterine affections* have been relieved by the local use of the extract, either smeared upon bougies or administered by injection. It is asserted also to be useful in *paraphimosis.* The inhalation of the vapor from a decoction of the leaves or extract has been recommended in *spasmodic asthma.* For this purpose, two drachms of the leaves, or fifteen grains of the aqueous extract, are employed to the pint of water. A much better plan is to smoke the dried leaves in the form of a cigarette or in a pipe.

Belladonna should never be given in substance, but in the form of extract or tincture, or, when accuracy or quickness of action is desired, of atropine. (See *Atropina.*)

Dose, one grain (0.065 Gm.).

"Benzaldehyde contains not less than 85 per cent. of $C_6H_5.CHO$." *U. S.*

Benzoic aldehyde; Oleum Amygdalarum Æthereum Artificiale; Aldéhyde Benzoique, *Fr.;* Benzaldehyd, Künstliches Bittermandelöl, *G.*

Preparation.—Benzaldehyde is the first in the series of aromatic aldehydes, being the first oxidation product of benzyl alcohol, $C_6H_5.CH_2OH$, and going in turn into the fuller oxidation product, benzoic acid, $C_6H_5.COOH$. It is mainly produced artificially from toluene by the following reactions:

$$C_6H_5.CH_3 + 2Cl_2 = C_6H_5.CHCl_2 + 2HCl$$
$$C_6H_5.CHCl_2 + HOH = C_6H_5.COH + 2HCl$$

By the action of chlorine upon the hot hydrocarbon, benzyl chloride, $C_6H_5CH_2Cl$, results, and this yields benzoic aldehyde on distillation with lead nitrate and water in an atmosphere of carbon dioxide gas. More generally, however, *benzal chloride,* $C_6H_5CHCl_2$, is taken, as this, when heated under pressure with water or sulphuric acid, readily yields the benzaldehyde. The product is purified by conversion into the acid sulphite compound.

It may be obtained pure by agitating it strongly with calcium hydroxide and a solution of ferrous chloride, submitting the mixture to distillation, and drying the oil which comes over by digestion with calcium chloride. Whipple (*A. J. P.,* xxvi) obtained benzaldehyde by treating the oil of bitter almond with a solution of silver nitrate—thus precipitating silver cyanide—and distillation.

Exposed to the air, benzaldehyde tends to pass by oxidation into benzoic acid, which latter is therefore liable to be found as a contamination of the sample of benzaldehyde if not freshly rectified.

Description and Physical Properties.—"A colorless or yellowish, strongly refractive liquid, having an odor resembling that of oil of bitter almond, and a burning aromatic taste. Benzaldehyde is soluble in about 350 volumes of water, and is miscible with alcohol, ether, and with fixed or volatile oils.

"Specific gravity: about 1.045 at 25° C. Shake 0.5 cc. of Benzaldehyde with 5 cc. of distilled water, add 0.5 cc. of sodium hydroxide T.S. and 0.1 cc. of ferrous sulphate T.S., and warm the mixture gently. Upon the addition to the mixture of a slight excess of hydrochloric acid, no greenish-blue color or blue precipitate is produced within fifteen minutes (*hydrocyanic acid*). Wind the end of a copper wire into a spiral about 6 mm. in diameter and 6 mm. in length, and hold it in a non-luminous flame until it glows without coloring the flame green. Cool the wire, dip the spiral in the Benzaldehyde, ignite, allow it to burn outside of the flame, and then bring the spiral into contact with the lower, outer edge of the non-luminous flame: not even a transient green color is imparted to the flame (*chlorinated compounds*). Dissolve 1 cc. of Benzaldehyde in 20 cc. of alcohol, and add distilled water until a slight turbidity is produced. Add zinc and diluted sulphuric acid, maintaining a brisk evolution of hydrogen for one hour. Filter, evaporate the liquid to about 20 cc., and boil 10 cc. of the evaporated liquid with 1 drop of potassium dichromate T.S.: no violet color is produced (*nitrobenzene*).

"**Assay.**—Dissolve about 3 cc. of freshly redistilled phenylhydrazine in 60 cc. of alcohol, and titrate 25 cc. of the solution (this solution must always be freshly prepared) with half-normal hydrochloric acid, using 1 or 2 drops of methyl orange T.S. as indicator. To about 1 Gm. of the Benzaldehyde, accurately weighed, add 25 cc. of the phenylhydrazine solution, and allow the mixture to stand for thirty minutes. Add 1 or 2 drops of methyl orange T.S., acidify with a measured excess of half-normal hydrochloric acid, and add 20 cc. of distilled water. Filter, and wash the precipitate with small portions of distilled water until the washings cease to redden blue litmus paper. Titrate the excess of hydrochloric acid in the filtrate with half-normal sodium hydroxide. Subtract the number of cc. of half-normal hydrochloric acid consumed from the number of cc. of half-normal hydrochloric acid used in titrating the 25 cc. of phenylhydrazine solution. The difference, multiplied by 0.05304, indicates the weight of $C_6H_5.CHO$ present.

"Preserve in small, well-stoppered bottles, protected from light." *U. S.*

Uses.—Benzaldehyde is used as a flavoring agent, in place of the oil of bitter almond, from which it differs in containing no hydrocyanic acid; it is often called *artificial* or *synthetic oil of bitter almond.* (See *Oleum Amygdalæ Amaræ.*) It is much less poisonous than the true oil of bitter almonds.

Dose, one-half to one minim (0.03–0.06 cc.).

BENZAMINÆ LACTAS. Br.

BENZAMINE LACTATE

"Benzamine Lactate, $C_{15}H_{21}NO_2,C_3H_6O_3$, is the lactate of benzoyl-vinyl-diaceton-alkamine, from which it may be obtained by neutralising with lactic acid." *Br.*

Betaeucaine Lactate; Eucaine Lactate.

"A white crystalline powder. Taste slightly bitter followed by a sensation of numbness. Soluble in 5 parts of *water,* and in 8 parts of *alcohol* (90 per cent.). Its aqueous solution yields with an aqueous solution of *salicylic acid* a white precipitate, and with *solution of ammonia* a white precipitate readily soluble in excess of the reagent. Treated with *nitric acid* and *alcoholic solution of potassium hydroxide* as rescribed under 'Cocainæ Hydrochloridum' a characteristic odor is evolved, recalling peppermint. Does not darken in color when moistened with *alcohol* (90 per cent.) and triturated with *mercurous chloride* (distinction from cocaine and α-eucaine). An aqueous solution (1 in 100) gives no precipitate with *solution of potassium iodide* (distinction from α-eucaine). Dissolves in *sulphuric acid* and in *nitric acid* without coloration. No appreciable ash." *Br.*

For further information concerning the chemistry and uses of this salt see *Eucainæ Hydrochloridum.*

BENZENUM. Br.

BENZENE

"Benzene, C_6H_6, is a liquid hydrocarbon obtained from light coal-tar oil." *Br.*

Benzene, Benzole, Phenyl Hydride, Benzen; Benzenum-Medicinale, *N.N.R.;* Benzinum, *Fr. Cod.;* Benzine, *Fr.;* Benzol *P. G.;* Phenylwasserstoff, Steinkohlenbenzin, *G.;* Benzolo, *It.*

It is to be regretted that the British Pharmacopœia (1914) has abandoned the name "Benzol" and adopted the name "benzene" for this product, and that the French Codex uses the word "Benzine" for crystallizable benzene. Benzol (Benzene, Br. Pharm. and U. S. P. reagent) must not be confounded with the commercial article *benzin,* which is a mixture of various hydrocarbons of light specific gravity, obtained in the distillation of petroleum. (See *Benzinum Purificatum.*) Originally the two names benzol and benzin were applied to the same substance, but after the discovery of petroleum it was found that the liquid obtained by distillation from coal tar was quite different from that obtained from petroleum. In the United States it has become the custom to call the liquid obtained by the fractional distillation of petroleum, having the specific gravity 0.638 to 0.660 at 25° C., *benzin.* It is unfortunate that in Europe, and on the Continent especially, the term benzin was used for both liquids. The two substances are essentially different although resembling each other somewhat in their solvent powers. Benzol is a definite hydrocarbon of fixed constitution, petroleum benzin a complex body of varying constitution. Benzol can be frozen; petroleum benzin has never yet been congealed. Petroleum benzin boils at from 45° to 60° C., while benzol boils at 79° to 80° C. Benzol can be converted into nitrobenzol, and by further treatment into aniline colors; petroleum benzin cannot. The term *benzene* is gradually becoming limited to the pure hydrocarbon, C_6H_6, while *benzol* is applied to the mixture of benzene with its homologues *toluene, paraxylene, metaxylene, mesitylene, pseudocumene,* etc. This view was probably in the minds of the revisers of the British Pharmacopœia (1914) and caused them to abandon the name "Benzol" and adopt "Benzene," thus signifying the purified product.

Benzene was discovered by Faraday in 1825 in the liquid obtained upon compressing illuminating gas. Hoffmann afterwards found a more abundant source in coal tar. For many years coal tar furnished the major portion of the benzene of commerce, but during the war the scarcity of the substance led to a search for new sources of supply. One of these, which furnishes much of the commercial product, is the by-product from coke ovens in which the volatile products of destructive distillation are collected and fractionated. Still another source is petroleum benzine. The aliphatic compounds in petroleum benzine are converted into cyclic compounds by heating the vapors under pressure. In this way benzene, toluene and other similar cyclic hydrocarbons are produced. Commercial benzol is found of varying degrees of purity on the market, as for many industrial purposes it is not necessary to free it from volatile impurities. The purest benzene, such as is used for reagent purposes, is obtained by the dry distillation of benzoic acid with lime. Benzene finds many uses in the industries for its solvent effect, and also has been employed as one of the immiscible solvents in the manufacture of alkaloids.

Benzol may be distinguished from benzin by the use of dracorubinresin which is dissolved by the former with a deep red color but is completely insoluble in the latter. When petroleum benzin is shaken in the cold with one-third of its volume of fused crystals of absolute phenol, the latter remains undissolved, while benzol is miscible with absolute phenol in all proportions. (Allen.) According to Pusch, benzol can be distinguished from petroleum benzin by the fact that benzol forms a violet-red and petroleum benzin a raspberry-colored solution with iodine.

Commercial benzol is always contaminated with more or less toluene and xylene. It is graded by such terms as "90 per cent. benzol" or "50 per cent. benzol." (See *Ph. Era,* 1918, p. 280.)

In consequence of the great volatility and extreme inflammability of benzol and its attendant hydrocarbons, much care is necessary both in their preparation and in their subsequent use in order to avoid any possible exposure to flame. Very serious accidents have taken place from want of the proper caution in this respect. Benzene vapor and air when mixed produce a highly explosive combination. The limit of maximum explosibility is from about 3 to 6 per cent. of benzene vapor in the air.

Properties.—The British Pharmacopœia describes benzene as "a colorless, mobile, inflammable liquid. Insoluble in *water,* but miscible with *absolute alcohol* or *ether.* Specific gravity 0.880 to 0.887. 95 per cent. distils between 79° and 82° C. It solidifies when cooled to 0° C., and if the temperature be allowed to rise, does not entirely re-melt below 4° C." *Br.*

"A colorless, transparent, liquid. Boiling point, 79° to 81° C. Congealing point, about 5° C. Specific gravity, about 0.876 at 25° C. Insoluble in water, miscible with alcohol, ether, and with fixed or volatile oils. When equal volumes of benzene and sulphuric acid are shaken together in a glass cylinder during fifteen minutes, the acid upon separation is not colored. Add a few mgm. of isatin, shake well, and allow to stand for thirty minutes. The acid does not acquire a blue or green color (*thiophene*). Non-volatile residue at 100° C., not over 0.01 per cent." *U. S.* (*Reagents.*)

Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine, and most resins and fats. It dissolves quinine, but not cinchonine, with which it forms a bulky gelatinous mass. Morphine and strychnine are sparingly soluble. Its solvent power over some of the organic alkaloids led John Williams, of London, to employ it in extracting them. Dragendorff has corroborated and extended this use of benzol for obtaining the alkaloids, whose salts are, however, not usually soluble in the menstruum. Benzol is also a solvent of many of the resins, of mastic, camphor, wax, fatty and oily substances, essential oils, caoutchouc, and gutta-percha. It often becomes a matter of great importance commercially to test the purity of commercial benzol, and a very thorough method of assay based on fractional distillation is found in Allen's commercial organic analysis. The following method, originating with Schorlemmer, is based on the conversion of this hydrocarbon into aniline, and of that into one of the characteristic colors derived from it. That part of the mixture which volatilizes at 150° C. is operated on. This is treated with fuming nitric acid, which, if benzol be present, gives rise to a nitrobenzol with its bitter-almond odor. The nitrobenzol is then converted by the action of granulated tin and hydrochloric acid into aniline, which is isolated by distilling the product with potassium hydroxide. The aniline floats on the top of the liquid that passes. A little of this gives with sodium hypochlorite a fine purple color; and a drop of it, if heated with a little corrosive sublimate, will yield the beautiful color of rosaniline. (*J. P. C.,* 4e sér., ii, 177.) According to Balls, magnesium ribbon, with the addition of a few drops of solution of platinic chloride, rapidly and completely reduces nitrobenzene in alcoholic solution to aniline, giving a solution which can be at once decanted and tested with bleaching powder. (Allen.)

Uses.—Benzol has been shown by Chassevant (*Archiv. de Pharmacodyn,* 1896, ii) to be depressant to the central nervous system and to the vasomotor system. It was experimented with as an anesthetic by Simpson, but was found scarcely capable of producing unconsciousness. In 1897 Guyot reported that habitual exposure to the fumes of benzol during its manufacture produced a chronic poisoning characterized by uncertainty of gait, mental disturbance, loss of sexual power, and epileptiform convulsions. Sanlessen found that, in lower animals, after death from benzol poison, there were hemorrhages into the lungs and the stomach, with various fatty degeneration, and a plastic bone-marrow. Selling (*J. H. H. B.,* 1910, xxi) reported fatal cases of human poisoning, showing the same lesions. His studies of these cases led Von Koranyi (B. K. W., 1912, xlix) to the use of benzol in the treatment of *leukemia.* Since this a large number of authors have reported favorable results in this intractable disease. Ravenna (*Rif. Med.,* 1920, xxxvi, 86) concludes, however, that its effects are only palliative, not curative. Barker has also reported favorable effects (*J. H. H. B.,* 1913) in *Hodgkin's disease* and McLester (*J. A. M. A.,* 1914, lxii) in *polycythemia.* It is best administered by mixing with equal parts of olive oil and emulsifying with mucilage of acacia. Bordarampé (*Rivista d. l. Assoc. Med. Argentina,* 1919, xxx, 237) has used it locally with asserted excellent results in inoperable *cancer.*

The remedy is evidently not harmless. Neumann (*Ther. Geg.,* 1913, p. 56) reports a case of leukemia in which benzol was given for thirty-six days with great reduction in the number of leukocytes, but after the drug was stopped the action continued, the leukocytes fell to 200, the patient developed fever, weakness, diarrhea and epistaxis, and died thirty-nine days after the last dose. A number of cases of serious poisoning, some of them fatal, have been reported by Ronchetti (*Giorn. di Clin. Med.,* Sept. 20, 1922) and by Hamilton (*J. A. M. A.,* 1922, lxxviii, 628) among workers in rubber factories where benzene was used as a solvent. Pappenheim (*W. K. W.,* 1913, p. 48) from experiments upon the lower animals finds that benzol is injurious to both the liver and kidney. Koranyi, however (*W. K. W.,* 1913), insists that in quantities of not over 3 Gm. per day benzol is perfectly safe, but generally smaller quantities are sufficient for therapeutic purposes. It should be noted that commercial benzol often contains toxic impurities, especially nitrobenzol and aniline. A crystallizable benzol is described in the N. N. R., under the name of *Benzenum medicinale;* it is liquid at ordinary temperatures.

The beginning *dose* is generally fifteen minims (0.9 cc.) cautiously increased to forty-five minims (2.8 cc.).

BENZINUM PURIFICATUM. U. S.

PURIFIED PETROLEUM BENZIN Benzin. Purif. [Petroleum Ether]

"Purified Petroleum Benzin is a purified distillate from American petroleum consisting of hydrocarbons, chiefly of the Methane series." *U. S.*

Benzin, Petroleum Ether; Æther Petrolei; Esprit (naphte, Ether) de Pétrole, *Fr.;* Benzinum Petrolei, *P. G.;* Petroleumbenzin, Petroläther, *G.;* Benzina del petrolio, *It.*

Purified petroleum benzin was introduced into the U. S. Pharmacopœia VIII and IX, and is used mainly as a solvent. The process of purification was not introduced into the U. S. IX, as the liquid is very inflammable and not suited for purification on the small scale by the pharmacist. The U. S. VIII process was as follows: "Potassium Permanganate, *ten grammes;* Sodium Hydroxide, *two grammes;* Sulphuric Acid, *sixty cc.;* Petroleum Benzin, *one thousand cc.;* Water, *a sufficient quantity.*

"Add the Acid to *five hundred and fifty cc.* of Water, and when the mixture has become cold, pour it into a bottle having the capacity of about two liters. Add *eight grammes* of Potassium Permanganate and agitate until it is dissolved, then add the Petroleum Benzin, in four portions, shaking the liquid after each addition. Allow the liquids to remain in contact for twenty-four hours, shaking the bottle at frequent intervals; then decant the Petroleum Benzin into another bottle of the same capacity, and having dissolved *two grammes* of Potassium Permanganate in *two hundred and forty cc.* of Water, in which the Sodium Hydroxide has previously been dissolved, mix the liquids and agitate the mixture frequently during several hours, then decant, repeat the washing with Water, and again decant the Purified Petroleum Benzin." *U. S. VIII.*

Description and Physical Properties.—"A clear, colorless, non-fluorescent, volatile liquid, having an ethereal or faint, petroleum-like odor, and a neutral reaction. *Caution.—It is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently.* Purified Petroleum Benzin is practically insoluble in water. It is freely soluble in alcohol, and is miscible with ether, chloroform, benzene, and with fixed or volatile oils, with the exception of castor oil.

"Specific gravity: 0.634 to 0.660 at 25° C. Purified Petroleum Benzin distils completely between 35° and 80° C., when determined by method II, page 433. Pour 10 cc. of Purified Petroleum Benzin in portions upon clean, odorless filter paper laid on a warm glass plate: no disagreeable or notably sulphureted odor becomes apparent as the last portions disappear from the paper, and no greasy stain remains. Not more than 0.001 Gm. of residue remains on evaporating 50 cc. of Purified Petroleum Benzin at a temperature not exceeding 40° C. Boil 10 cc. of Purified Petroleum Benzin for a few minutes with one-fourth its volume of alcoholic ammonia T.S. and a few drops of silver nitrate T.S.: the liquid does not turn brown (*pyrogenous products or sulphur compounds*). Add 5 drops of Purified Petroleum Benzin to a mixture of 40 drops of sulphuric acid and 10 drops of nitric acid in a test tube, warm the liquid for about ten minutes, set it aside for half an hour, and dilute it with water in a shallow dish: no odor of nitrobenzene is evolved (*benzene*).

"Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

Benzin is a very inflammable liquid. This inflammability may be somewhat reduced by the addition of carbon tetrachloride, but it has been found that even as high an admixture as 70 per cent. of carbon tetrachloride will not make benzin entirely uninflammable. When benzin vapor is mixed with air it becomes highly explosive.

This useful product of petroleum was first introduced into the U. S. Pharmacopœia (1880); it is obtained in the process of purifying petroleum by fractional distillation. (See *Petroleum,* Part II.) Petroleum benzin must be carefully distinguished from benzene (official in the British Pharmacopœia under the name of *Benzenum* and a reagent in the U. S. P.), a product derived from coal tar. Although the U. S. Pharm. gives a test to distinguish an admixture with benzene, this adulteration of petroleum benzin is hardly likely to take place here in the near future, because of the great difference in price. The principal consumption of petroleum benzin at present is in the arts as a solvent, especially as a substitute for oil of turpentine, which it resembles very much in its solvent properties. In pharmacy it has been used to deprive powdered drugs of their fixed oil by percolation; to obtain volatile oils by percolating the oily drug with the benzin and subsequently evaporating the mixture spontaneously; as a substitute for ether in making oleoresins; and for many other purposes to which it is adapted on account of its powers as a solvent. Petroleum benzin is a good solvent for fats, resins, rubber, and some of the alkaloids.

Dragendorff recommends the rectification of benzin by fractional distillation from lard, collecting the portion which distils below 45° C. Petrolatum has also been found to be efficient in retaining the impurities in the still.

Uses.—Not only benzin, but various other commercial mixtures derived from petroleum, such as gasoline and naphtha, have been used by depraved humanity for the purpose of producing intoxication. (See *Petroleum,* Part II.)

Jaffé (*M. M. W.,* 1914, lxi) concludes from an experimental investigation, as well as from the study of cases of human poisoning, that the most marked effect of benzin is extensive hemorrhage in the lungs, which he believes is due to an effort at elimination. It has been largely used as a solvent for iodine in the disinfection of the skin, but if evaporation is prevented it has a marked irritant effect and even a caustic action, indeed Sehrwald (*D. M. W.,* 1913, p. 318) has recommended it clinically as a counter-irritant.

Purified benzin is official in the Pharmacopœia purely for pharmaceutical properties. It is not used in medicine. It was at one time suggested by Schleich as a diluent for chloroform in producing surgical anesthesia, but H. C. Wood, Jr. (*P. M. J.,* April 15, 1899), showed that it was a direct depressant to both the heart and vasomotor system far beyond its power as a narcotic, and the method practically yielded such unfavorable results that it was soon abandoned.

A number of cases of benzin poisoning, both acute and chronic, have been reported. In the acute cases the most constant symptom has been disturbance of intellection, or unconsciousness, with slowing of the respirations. The pulse is generally somewhat slower than normal, pupils dilated, the surface cold, and frequently there has been cyanosis and occasionally convulsions. In most of the cases whether the poison has been swallowed or inhaled, the benzin odor can be peceived upon the breath. (For report of cases see Wichern, *M. M. W.,* lvi, p. 11.) In the chronic cases the symptoms have been headache, giddiness, numbness and paresthesia of the extremities, vomiting, loss of memory, general weakness, especially in the legs, tenderness and pain along the nerve trunks, and progressive anemia. In acute cases it causes a peculiar intoxication, having the appearance, at the onset, of an attack of hysteria, with laughing, tremors, mydriasis, nystagmus, loss of power in the legs and bladder, failing heart action, delirium, coma and death. In nine fatal cases of chronic poisoning by petroleum benzin, Santesson found a widespread fatty degeneration affecting especially the liver, kidneys and cardiac muscles.

Off. Prep.—Used as a solvent for the fatty substances in various drugs.

BENZOINUM. U.S., Br.

BENZOIN Benzoin.

"Benzoin is a balsamic resin obtained from *Styrax Benzoin* Dryander and other species of *Styrax* (Fam. *Styraceæ*), and known in commerce as Sumatra Benzoin and Siam Benzoin.

"Sumatra Benzoin yields not less than 75 per cent. of alcohol-soluble extractive and not more than 1 per cent. of acid-soluble ash. Siam Benzoin yields not less than 90 per cent. of alcohol-soluble extractive, contains not more than 1 per cent. of foreign organic matter, and yields not more than 0.5 per cent. of acid-soluble ash." *U. S.*

"Benzoin is a resinous solidified balsam obtained from the incised stem of Styrax Benzoin *Dryand.* Known in commerce as Sumatra Benzoin." *Br.*

Resina Benzoe, Asa Dulcis; Gum Benjamin; Benjoin, *Fr.;* Benzoë, *P. G.;* Benzoëharz, *G.;* Benzoino, *It.;* Benjui, *Sp.*

It is generally believed that Siam Benzoin is obtained from *Styrax Benzoin* Dryander. It appears to closely resemble the tree growing in Sumatra, which yields a balsamic resin bearing this name. Tschirch considers that the trees yielding Siam and Sumatra Benzoin are physiological varieties of the same species. (Tschirch, *"Harze,"* II. Aufl., p. 195.) Rordorf (*Schweiz. Apoth. Ztg.,* 1917) concludes that the tree producing Siam Benzoin, while very similar to the *S. Benzoin,* offers distinct differences and proposes a new species, *S. Siamensis* (Rordorf.) Strueff presents a careful morphological paper on the trees of *Styrax Benzoin,* growing in Siam, Sumatra and Java, in *A. Pharm.,* 1911, p. 10.

Styrax Benzoin, or *Benjamin Tree,* is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above and downy beneath. The bowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang, all on the same side, upon short slender pedicels. The tree is a native of Sumatra, Java, Borneo, and other islands in the vicinity. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure and forms the *Sumatra Benzoin* of commerce. According to the researches of A. Tschirch (*Journ. Roy. Microscop. Soc.,* 1890), the exudation is purely the result of pathological processes, the plant containing no resin receptacles. The trees, which are either wild or cultivated, are deemed of a proper age to be wounded at six years, when the trunks are usually about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin.

The tree which yields the Siam Benzoin is not certainly determined. According to E. M. Holmes its leaves are thinner and less distinctly venated than those of the Styrax Benzoin. Hartwich believes it to be a new species, *Styrax benzoides* Carib (see *Kew Bulletin,* 1912, p. 391). Holmes (*P. J.,* 1916) attributes it, however, to the *S. tonkinense.* Rordorf (*P. J.,* 1917, xcix, p. 111) received some fruits which were sent him from Bangkok as specimens supposedly derived from the Benzoin tree; these do not agree with any species previously described and he proposed a new species, *S. Siamensis* Rordorf. The territory from which the balsam is derived is a quite limited district in the Province of Laung Probang along the River Mekong.

The *Siam Benzoin* appears in commerce either in the form of separate tears or in masses composed of tears cemented together by a rich amber-colored translucent resin, these masses usually being in cubical blocks which take their form from the wooden boxes in which the soft resin has beeen packed. The tears are small, mostly less than 2 or 3 cm, in length, opaque, brittle and milky white on the interior, but on keeping gradually oxidize into the brownish translucent resin. The finest variety is composed almost entirely of these tears, loosely agglutinated together. *Sumatra Benzoin* is sent into commerce chiefly from Acheen in Sumatra. It differs from the Siam varieties in having a much grayer color; the resin is grayish-brown, the tears are usually fewer than in the finer variety, and the bits of wood, etc., more abundant. The odor differs from, and is less agreeable than, that of Siam Benzoin. *Palenbang Benzoin* resembles Sumatra Benzoin, but is somewhat more transparent, and is stated to yield a larger percentage of benzoic acid. It is also asserted that is can be distinguished by its tincture, when dropped into water, not producing milkiness, but a flocculent deposit. *Penang Benzoin* also resembles Sumatra Benzoin, but has an odor which is more like that of storax, and it is probably yielded by the *Styrax Benzoin;* possibly it is the product of one of the Sumatran species, *S. subdenticulata* Miq. For an account of the cultivation and collection of benzoin in Sumatra, by L. M. Vonck, see *C. D.,* 1891, 486–488; also *D. C.,* 1891, 258. Lüdy made an investigation of the bark and wood of a benzoin tree which was brought from Java by Tschirch. He reached the conclusion that benzoin balsam was produced from the tannin of the bark. (*A. Pharm.,* 1893, 43, 95.) A variety of benzoin known as *Estoraque* or *Benjui,* is produced in Bolivia from the *Styrax Pearcei* Perk. var. *bolivianus.* This has been shown by Wichmann (*S. W. P.,* 1912, p. 237) to be of similar composition to the Asiatic resin. According to this author resins are also collected from a number of other species of *Styrax* in South America.

Properties.—Benzoin has a fragrant odor, with very little taste, but when chewed for some time leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish-brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. After long storage it becomes covered with a thin yellow transparent film which Reinitzer finds is due to oxidation of the proper resin (*Schim. Rep.,* April, 1915). In the inferior kinds the white spots are very few, or entirely wanting. Benzoin is easily pulverized, and, in the process of being powdered, is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. The U. S. Pharmacopœia recognizes both Sumatra and Siam Benzoins. The official descriptions of these follow:

"*Unground Sumatra Benzoin.*—Blocks or lumps of varying size, made up of tears, compacted together with a reddish-brown, reddish-gray, or grayish-brown resinous mass; tears externally yellowish or rusty-brown, milky-white on fresh fracture; hard and brittle at ordinary temperatures, but softened by heat and becoming gritty on chewing; odor aromatic. When digested with boiling water the odor suggests cinnamic acid or storax; taste aromatic and slightly acrid.

"*Unground Siam Benzoin.*—Pebble-like tears of variable size, compressed, yellowish-brown to rusty-brown externally, milky-white on fracture, separate or very slightly agglutinated, hard and brittle at ordinary temperatures but softened by heat and becoming plastic on chewing; odor agreeable, balsamic, vanilla-like; taste aromatic and slightly acrid.

"The solution of Benzoin in alcohol becomes milky upon the addition of water and is acid to litmus paper. Heat a few fragments of Benzoin in a test tube: Sumatra Benzoin evolves a sublimate consisting of plates and small, rod-like crystals that strongly polarize light. Siam Benzoin evolves a sublimate directly above the melted mass consisting of numerous long, rod-shaped crystals, which do not strongly polarize light. Treat about 0.25 Gm. of Benzoin with 5 cc. of ether, decant about 1 cc. of the ethereal solution into a porcelain dish, and add to it 2 or 3 drops of sulphuric acid: the solution of Sumatra Benzoin produces a deep red-brown coloration of the sulphuric acid and the solution of Siam Benzin produces a deep purplish-red cloration. Heat about 0.5 Gm. of Benzoin in a test tube with 10 cc. of potassium permanganate T.S.: only the Sumarta variety develops in odor of benzaldehyde. Treat about 1 Gm. of powdered Benzoin with 15 cc. of warm carbon disulphide, filter, wash the filter with an additional 5 cc. of carbon disulphide, and allow the filtrate to evaporate spontaneously: the residue does not exceed 12.5 per cent. This residue responds to the tests for identity under *Acidum Benzoicum.* Benzoin does not show the presence of *rosin.*

"**Assay.**—Proceed as directed under alcohol-soluble extractive." *U. S.*

"Hard brittle masses consisting of numerous whitish tears embedded in a greyish-brown translucent matrix. Odor agreeable, similar to that of storax; taste slightly acrid. When cautiously heated in a dry test-tube it melts and evolves whitish fumes with an irritating odor. When 0.5 gramme is slowly heated to about 40° C. with 10 millilitres of *solution of potassium permanganate* an odor of benzaldehyde is evolved (distinction from Siam Benzoin). Not more than 15 per cent. insoluble in *alcohol* (90 per cent.). Ash not more than 5 per cent." *Br.*

When heated it melts, and emits thick, white, pungent fumes, which excite coughing when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol, and is precipitated by water from the solution, rendering the liquid milky. It yields to boiling water a notable proportion of benzoic acid. Lime water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of other acids.

The percentage of alcohol-soluble matter require to be present by the U. S. P. in benzoin is very high, and if rigidly enforced by the customs would exclude Sumatra Benzoin in all but its very finest varieties. Robt. C. Pursel and Willard Graham obtained from five commercial varieties of Sumatra Benzoin, in the American market, an average of 86 per cent. of soluble matter. (*Proc. Pennsylvania Pharm. Assoc.*, 1902.) John Barclay, in England, found the average of ten samples to be 69.9 per cent. (*P. J.*, Jan., 1903.)

Benzoin retards the oxidation of fatty matters, and thus tends to prevent rancidity.

Constituents.—The chief constituents of benzoin are resin, benzoic and cinnamic acids and their esters. The resinous portion, which constitutes about three-fourths of the drug, is made up of esters of *benzoresinol* (*siaresinol*), constituting from 7 to 8 per cent. of the resin, and of an undetermined alcohol. This latter has been stated to be *sumaresinotannol.* Zinke and Dzrimal (*J. P. C.*, 1921, xxiv, 350) report the presence of a distinctive compound *lubanyl benzoate*, $C_6H_3OH.OCH_3.CH{=}CH.CH_2O.CO{-}C_6H_5$. This occurs in crystalline masses melting at 72° C.

The total amount of free acids is from 15 to 17 per cent. In the Sumatra Benzoin cinnamic acid predominates, and in the Siam Benzoin benzoic acid is more abundant; indeed Beckurts and Brueche state that Siam Benzoin contains no cinnamic acid (see also Tschirch and Lüdy, *A. Pharm.*, 1893, 500). There is present also some 9 or 10 per cent. of esters of these acids, cinnamyl, cinnamate, phenylpropyl cinnamate, and traces of vanillin, benzaldehyde, *styrol* and *styracin.*

Benzoin may be rapidly tested for cinnamic acid by heating a small quantity with a little soda and water and warming the filtrate with potassium permanganate, when the odor of bitter almond will be developed. (*A. Pharm.*, 1892, ccxxx.)

Aschoff recommends the following method of detecting cinnamic acid. Boil the benzoin with milk of lime, filter, decompose with hydrochloric acid, and add either potassium dichromate with sulphuric acid, or potassium permanganate, when, if cinnamic acid be present, the odor of oil of bitter almond will be perceived.

According to T. T. Cocking and J. D. Kettle (*Tr. Br. Ph. Conf.*, 1914, 357), the important analytical data to be considered in valuing benzoin are (1) the percentage soluble in 90 per cent. alcohol, and (2) the quantity of aromatic acids present, both free and combined. Methods of obtaining these factors are given in detail and also tables giving the results of such examinations of a number of commercial samples. Reinitzer (*A. Pharm.*, cclii) has made an exhaustive study of Siam Benzoin, in which he contradicts some of the previously published statements of Tschirch and Lüdy. He claims that the resinotannol of these authors does not exist in the drug, but is an oxidation product created during the analysis.

Rump (1878) treated Siam Benzoin with caustic lime, precipitated the benzoic acid with hydrochloric acid, and agitated the liquid with ether. The latter on evaporating afforded a mixture of benzoic acid and vanillin, $C_8H_8O_3$. Subjected to dry distillation, benzoin affords, as the chief product, benzoic acid, together with empyreumatic products, among which Berthelot has proved the presence (in Siam Benzoin) of *styrol*, C_8H_8. The latter was also obtained in 1874 by Theegarten from Sumatra Benzoin by distilling it with water. (*B. Chem. G.*, 1874.)

Sumatra Benzoin is sometimes heavily adulterated with stony débris, sand and bark. Schneider reports finding as much as 75 per cent. of bark in a commercial article.

Uses.—Benzoin acts as a stimulating expectorant, and was formerly employed in pectoral affections, but, except as an ingredient of the compound tincture of benzoin, it has fallen into disuse. Trousseau and Pidoux recommend strongly its inhalation in *chronic laryngitis.* Either the air of the chamber may be impregnated with its vapor by placing a small portion upon some live coals, or the patient may inhale the vapor of boiling water to which the balsam has been added. It is occasionally employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); the milky liquor resulting from the addition of water to its alcoholic solution is sometimes used as a cosmetic, under the impression that it renders the skin soft. A tincture has been strongly recommended in *anal fissure.* In the East Indias, the balsam is burnt by the Hindus as a perfume in their temples of worship.

Dose, fifteen to thirty grains (1–2 Gm.).

BERBERIS. N. F., Br.

BERBERIS Berber [Oregon Grape Root]

"Berberis consists of the dried rhizome and roots of species of the section *Mahonia* (Nuttall) De Candolle of the genus *Berberis* Linné (Fam.

Berberidaceæ). Berberis contains not more than 5 per cent. of the overground parts of the plant or other foreign organic matter. Reject pieces of the rhizome or root over 45 mm. in diameter or with the bark removed." *N. F.*

Oregon grape root; Nepaul Barberry; Barberry; Epine-vinette, Vinettier, Ecorce de Racine de Berbérides, *Fr.;* Fauerach, Gemeiner Sauerdorn, Berberitze, Berberitzen-(Saurach-) Wurzelrinde, *G.;* Berbero, *It., Sp.*

The genus *Berberis* (Fam. *Berberidaceæ*) is a large one, comprising shrubs or trees which are widely distributed throughout temperate regions and in the mountains of the tropics. There are three well-defined medicinal groups: (1) The Rocky Mountain group, including *Berberis Aquifolium,* which yields the Oregon Grape Root. (2) The Asiatic group, which includes *B. aristata* DC., a shrub indigenous to India and Ceylon, and is recognized by the British Pharmacopœia. (3) The European group, which includes the common Barberry (*B. vulgaris* L.), which is naturalized in New England. According to Dragendorff (*Die Heilpflanzen*), about forty different species of berberis have been used in medicine.

Lycium, or *λύκιον* of the ancients, highly valued as a local application in affections of the eye and eyelids, and used for various other purposes, is supposed to be the medicine still used in India for the same affections, under the name of *rusot* or *ruswut,* which is an extract from various species of berberis combined with opium.

Berberis aristata, which furnishes the berberis of the British Pharmacopœia, is a shrub indigenous to the temperate Himalayas, extending from Bhután to Kanawar, the Nilgiri Hills, and Ceylon. It is erect and branching, the leaves being evergreen, obovate or oblong, entire, sometimes possessing spinose teeth. The flowers are yellow and occur in compound, often corymbose racemes. The stigmas are distinguished by being small and subglobose. The berries are few-seeded and taper into a short style. Several varieties of this species are recognized, viz., *floribunda* and *micrantha.* The type *B. aristata* closely resembles *B. asiatica* Roxb., *B. Lycium* Royle and *B. vulgaris* L., and consequently are mistaken throughout India. The same vernacular names are frequently applied to each of these plants and the same medicinal properties attributed to all.

The N. F. IV recognizes, under the title Berberis, "the rhizome and roots of species of the section *Mahonia* Nuttall of the genus Berberis." This section corresponds to the genus *Odostemon* of Rafinesque, and includes *B. Aquifolium* and *B. Nervosa.*

Berberis Aquifolium Pursh., *Berberis,* U. S. VIII, *Oregon Grape Root, Rocky Mountain Grape, California Barberry, Holly-leaf Barberry, Trailing Mahonia.*

The *Oregon grape* is a tall shrub, about six to seven feet high, with evergreen, coriaceous, bright and shining leaves, and having numerous small, yellowish-green flowers in the early Spring, and later clusters of purple berries containing an acid pulp. It is a native in woods from Colorado to the Pacific Ocean, especially abundant in Oregon and northern California.

Rusby believes that a large part of the berberis collected in Oregon is obtained from *B. Nervosa.* (*Ph. Era,* 1909, p. 633.)

Nepaul Barberry (*Berberis vulgaris* L.) is a native of Europe, but grows wild in waste ground in the eastern parts of New England, and is sometimes cultivated in gardens on account of its berries. It is a spreading shrub, from four to six feet or more in height, with thorny branches, a light gray bark and a fine yellow wood.

The *berries* of *B. vulgaris,* which grow in loose bunches, are oblong and of a red color, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent and antiscorbutic, and are used in Europe, in the form of drink, in *febrile diseases* and *diarrheas.* An agreeable syrup is prepared from the juice, and the berries are sometimes preserved for the table. The bark of the root of *B. vulgaris* L. was formerly included in the secondary list of the U. S. Pharmacopœia, under the name of *Berberis.* The root and inner bark have been used for dyeing yellow. The bark of the root is grayish on the outside, yellow within, very bitter, and stains the saliva when chewed.

Algerita Root, which has been used by Mexicans and old settlers in Western Texas, is derived from *Berberis trifoliatus* Moric [*Odostemon trifoliatus* (Moric.) Heller]. The shrub grows in Western Texas and New Mexico and extends into Mexico. The root contains, according to Hart (*A. J. P.,* 1916, p. 301), 1.3 per cent. of berberine and 0.1 per cent. of associated alkaloids. Hydrastine is absent. Infusions of algerita root are used for *eye sores,* while chewing the roots is considered reliable as a corrective for *sore mouths.* Injections of an infusion have been used for *gonorrhea.*

The commercial supplies of berberis used in the United States are obtained from Trieste and Oregon.

For a description of the bark of *B. aristata* DC., by Hartwick, see *Ph. Rev.,* 1896, 232.

Description and Physical Properties.—"*Unground Berberis.*—Cylindrical, more or less knotty, strongly branched, usually cut into pieces of varying length and up to 45 mm. in diameter; usually splitting somewhat on drying; externally light yellowish brown, longitudinally wrinkled and short scaly; fracture hard and tough; bark 1 mm. in thickness, easily separable into layers; wood yellow, the color more pronounced upon wetting, distinctly radiate, and showing rings of growth; pith of rhizome small, sometimes excentric. Odor slight; taste distinctive, very bitter; on chewing it tinges the saliva yellow.

"*Powdered Berberis.*—Yellowish-brown; composed chiefly of fragments of medullary rays, and wood fibers associated with a few tracheæ; wood fibers yellowish, with large, simple, transverse pores; tracheæ chiefly with bordered pores, occasionally reticulate; starch grains simple or 2- to 3-compound, the individual grains being irregularly spherical, 0.003 to 0.020 mm. in diameter, or occasionally larger." *N. F.*

The berberis of the British Pharmacopœia occurs "in undulating pieces from two and a half to five centimetres in diameter. Cork orange-brown, removed in places showing the subjacent darker brown cortex; marked with slightly wavy longitudinal striæ and occasional shallow transverse depressions. Transverse section shows a narrow brown cork; a broad, dark brown bast traversed by conspicuous yellow medullary rays; a bright yellow wood composed of numerous narrow vascular rays, containing many vessels, separated by narrow, paler medullary rays. Slight odor; taste bitter." *Br.*

Constituents.—Both the *B. vulgaris* and *B. aquifolium* contain three alkaloids of which the most important is *berberine*, $C_{20}H_{17}O_4N$. This alkaloid is found in numerous other plants of several natural orders, including *Hydrastis, Argemone, Coptis, Xanthoxylum*, etc. It occurs as golden-yellow crystalline needles, differing from most other alkaloidal bases in being soluble in water, yielding yellow solutions. It is also soluble in chloroform or benzol, but almost insoluble in ether or petroleum benzin.

Besides berberine Hesse (*B. Chem. G.*, 1886, xix, 3190) found *berbamine*, $C_{18}H_{19}O_3N$, and *oxyacanthine*, $C_{19}H_{21}O_3N$. For general properties and color reactions of these alkaloids see Rudel (*J. Chem. S.*, 1892, p. 641) and Pommerehne (*A. Pharm.*, 1895, ccxxxiii, p. 127).

Uses.—The various species of berberis appear to have similar medical properties. The alkaloid berberine is physiologically very feeble. (See *Hydrastis.*) Antiperiodic properties have been attributed to it, and T. Lascarato (*La Grèce médicale*, 1899, No. 2) affirms that it has a specific action upon the spleen which renders it very valuable in the treatment of malarial *splenic enlargement*, and that it is so powerful in producing contraction that when the spleen is softened large doses may produce splenic rupture, with *fatal hemorrhage.* The crude drug probably has no real medicinal effect, except that of a bitter tonic and mild laxative. It is by some believed to have an especial tendency towards the liver and hence is used in *jaundice* and *chronic hepatitis.* It is also stated to have alterative powers and has been employed in *syphilis* and *scrofula.*

Dose, from fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Tinctura Berberidis, *Br.;* Fluidextractum Berberidis, *N. F.*

BETANAPHTHOL. U. S. (Br.)

BETANAPHTHOL Betanaph. [Naphtol, U. S. 1890, Naphthol]

"Beta-monohydroxy naphthalene [$C_{10}H_7$-OH]." *U. S.* "Beta-naphthol, or beta-monohydroxy-naphthalene, $C_{10}H_7OH$, may be obtained from naphthalene-sulphonic acid." *Br.*

Naphthol, *Br.;* β-Naphthol, Beta-mono-hydroxy-naphthalene, Iso-naphthol; Naphtol β, *Fr. Cod.;* Naphtylol-β, *Fr.;* Naphtholum, *P. G.;* Beta-Naphtholum, *G.;* Naftol β, *Sp.*

On digesting four parts of naphthalene with three parts of sulphuric acid at 80° C. there is formed α- and *β-naphthalene sulphonic acids,* $C_{10}H_7SO_3H$, which may be separated by means of the barium or lead salts. When heated with sulphuric acid, the α acid passes into the β variety; therefore the latter acid is exclusively produced at higher temperatures, 160° C. Both of the naphthalene sulphonic acids, when fused with alkaline hydroxides, yield the corresponding naphthols, which are designated as α- and β *naphthol,* respectively. The second of these, betanaphthol, is the official naphthol, $C_{10}H_7OH$. It bears to naphthalene the same relation that phenol does to benzene.

Description and Physical Properties.—"Colorless or pale buff-colored, shining crystalline leaflets, or a white or yellowish-white, crystalline powder. It has a faint, phenol-like odor, and is stable in the air. One Gm. of Betanaphthol is soluble in about 1000 cc. of water, 0.8 cc. of alcohol, 17 cc. of chloroform, and in 1.3 cc. of ether, at 25° C. One Gm. is soluble in 80 cc. of boiling water. It is soluble in glycerin and in olive oil and is readily dissolved by solutions of alkali hydroxides. It sublimes readily when heated, and volatilizes with the vapors of alcohol and of water.

"Betanaphthol melts between 120° and 122° C. A cold, saturated, aqueous solution of Betanaphthol, when mixed with ammonia water, develops a faint, bluish fluorescence. Add about 0.1 Gm. of Betanaphthol to 5 cc. of an aqueous solution of potassium hydroxide (1 in 4), then add 1 cc. of chloroform, and gently warm the mixture: the aqueous layer acquires a blue color, changing afterwards, successively, to green and brown. Ferric chloride T.S. produces a greenish color in a cold, saturated, aqueous solution of Betanaphthol, and after some time causes the separation of whitish flakes, which turn brown upon the application of heat.

"Shake 1 Gm. of Betanaphthol with 100 cc. of distilled water at frequent intervals for fifteen minutes, and filter: the filtrate is neutral to litmus paper. Ash: not more than 0.05 per cent. Dissolve 0.5 Gm. of Betanaphthol in 25 cc. of ammonia water: no residue remains (*naphthalene*), and the solution does not have a deeper color than pale yellow (*other organic impurities*). Boil 0.1 Gm. or Betanaphthol with 10 cc. of distilled water until dissolved, allow the solution to cool, and then filter: the addition to the filtrate of 0.3 cc. of normal sodium hydroxide, followed by 0.3 cc. of tenth-normal iodine, produces no violet color (*alphanaphthol*).

"Preserve in well-closed containers, protected from light." *U. S.*

The British Pharmacopœia describes it as "white, or nearly white, crystalline lamellæ, or in powder. Odor resembling that of phenol; taste sharp, pungent. Soluble in about 1000 parts of *water,* and in 75 parts of boiling *water,* the solutions being neutral to *litmus;* soluble in less than 2 parts of *alcohol* (90 per cent.); very soluble in *ether,* in *chloroform,* and in *solution of sodium hydroxide.* Melting point 122° C. A hot saturated aqueous solution develops a blue fluorescence on the addition of 1 drop of *solution of ammonia.* A cold saturated aqueous solution yields a white turbidity with *solution of chlorine,* which, on the addition of excess of *solution of ammonia,* gives place to a green or brown coloration. 0.1 gramme dissolved in 10 millilitres of boiling *water* yields with 10 drops of an aqueous solution (1 in 30) of *ferric chloride* a white precipitate becoming brown, but not violet (absence of alpha-naphthol). No appreciable ash." *Br.*

Gugliamelli finds an arseno-tungstic reagent to give an intense blue color with alphanapthol and no color with bentanaphthol. Deniges employs a sulphotitanic reagent for differentiating between the two naphthols. This gives a green color with the alpha and a red color with the beta variety.

For Yvon's tests to distinguish between alpha- and betanaphthol, see *Proc. A. Ph. A.,* 1892, 955; see also *Chem. News,* 1892, 18. For Liebman's test for the presence of alphanaphthol, see *M. R.,* 1897, 281. See *Alphanaphthol* (Part II).

Uses.—Betanaphthol is locally irritant to mucous membranes, but on account of its insolubility cannot exercise a caustic effect in aqueous solutions. It is powerfully germicidal. Sternberg found that a solution of 1 part in 2000 would destroy the cholera spirillum after 15 minutes' exposure, and Schneider (*Z. Hyg.,* 1906, lii) finds that it is four times as active as lysol. As an antiseptic it is still more efficient, 1 part in 10,000, according to Maximovitch, being sufficient to prevent the development of all bacteria tested.

As a surgical disinfectant it is not commonly used but has been widely employed in *skin diseases* such as *favus, scabies,* etc., for its parasiticide effect. For this purpose it may be applied in the form of an ointment in strengths of from ½ to 5 per cent. Sloboziano (*G. M. P.,* 1920) highly recommends a 5 to 10 per cent. alcoholic solution of betanaphtol in the treatment of itch; he asserts that the betanaphthol has an anesthetic effect which allays the itching and a positive germicidal effect which destroys the parasite.

The most important uses of betanaphthol, however, are based on its relatively low toxicity which makes it one of the most valuable intestinal antiseptics that we possess in the treatment of *enteritis, intestinal fermentation* and similar conditions. More recently it has been considerably used as a vermifuge, especially in the treatment of *uncinariasis.* Schultz (*J. A. M. A.,* 1911, lvii, p. 1103) recommended for this purpose the administration of fifteen to thirty grains (1–2 Gm.) mixed with one-third its weight of milk sugar and enclosed in a capsule, followed by a cathartic. Certain South American physicians have recommended much larger doses, as high as 6 Gm. (90 gr.). From these quantities from 75 to 85 per cent. of cures have been reported, but Smille (*J. A. M. A.,* 1920, lxxiv, p. 1503) in seventy-nine cases had four in which there was severe destruction of the red blood cells and concludes that such doses are too toxic to be justifiable.

It has also been used as a food preservative, both under its proper name and under fanciful trade names, but this use is forbidden by law. The calcium salt known as abrastol, which is used for the same purpose, is described in Part II.

Dose, as an intestinal antiseptic, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Pasta Betanaphtholis, *N. F.;* Petroxolinum Betanaphtholis, *N. F.*

BETEL. Br.

BETEL

"Betel consists of the dried leaves of Piper Betle, *Linn.*" *Br.*

Betel, Betle, Pawn, or *Pinang* are popular Oriental names for *Piper Betle* L. and *P. Siriboa* L., the leaves of which are used by the Malays as a masticatory. The leaves are usually admixed with scrapings of the Areca nut and lime. The betel plants are indigenuous throughout the entire Indian-Malay region and cultivated in Madagascar, Bourbon and West Indies. The plants are climbing shrubs and trained upon trellises and poles in shady but hot places. The leaves are picked while green, pressed together by means of stones and dried.

Betel leaves of the British Pharmacopœia are described as follows: "About fifteen centimetres long, broadly ovate, acuminate, obliquely cordate at base; thin and brittle, upper surface glossy, five or seven conspicuous lateral veins. Mesophyll contains abundant oil-cells filled with brown oleo-resin. Taste warm, aromatic, bitter. As found in commerce the leaves are frequently tied up or stitched together into packets." *Br.*

The warm aromatic taste of the betel leaves is due to an essential oil known as *betel oil.* This is of a color varying from clear yellow to dark brown and of aromatic, somewhat creosote-like odor and burning sharp taste. The specific gravity ranges from 0.958 to 1.044, the lighter oil being that obtained from the fresh leaves. The alcoholic solution of the oil gives a greenish to bluish-green color with ferric chloride.

The betel oil from Siam contains cadinene and a characteristic phenol named *betelphenol,* isomeric with eugenol; the oil from Java contains in addition to the betelphenol, chavicol and a sesquiterpene; while the Manila oil contains betelphenol as the sole phenolic constituent. (Gildemeister and Hoffmann, *Die Ætherische Oele,* 1899.)

Uses.—The essential oil of betel is an active local stimulant and has been used in *doses* of one to two minims (0.06–0.12 cc.) in the treatment of various respiratory *catarrhs,* and as a local application, either by gargle or inhalation, in *diphtheria.* It is said that the juice of four leaves is equivalent in power to one drop of the oil. In India betel leaves are used locally to a considerable extent for the purpose of counter-irritation and applied to the mammary glands for the purpose of suppressing the secretion of milk in *mammary abscesses.* The essential oil has been given internally in doses of from one to two minims (0.06–0.12 cc.).

BISMUTHI SUBCARBONAS. U. S. (Br.)

BISMUTH SUBCARBONATE Bism. Subcarb. [Basic Bismuth Carbonate, Bismuth Oxycarbonate]

" Bismuth Subcarbonate is a basic salt of varying chemical composition, which, when dried to constant weight at 100° C., yields upon ignition not less than 90 per cent. of bismuth oxide [Bi_2O_3]." *U. S.* " Bismuth Oxycarbonate, $(Bi_2O_2CO_3)_2,H_2O$, may be obtained by the interaction of bismuth nitrate and ammonium carbonate." *Br.*

Bismuthi Carbonas, *Br.;* Carbonate of Bismuth, Oxycarbonate of Bismuth, Bismuthyl carbonate; Bismuthum Subcarbonicum, Subcarbonas Bismuthicus; Souscarbonate de Bismuth, *Fr.;* Basisches Kohlensaures Wismutoxyd, Wismutsubcarbonat, *G.*

A process for this salt is no longer official; that of the U. S. P., 1870, will be found in *U. S. D.,* 19th edition, p. 239.

Description and Physical Properties.—" A white or pale yellowish-white powder. It is odorless and tasteless, and is stable in the air. Bismuth Subcarbonate is insoluble in water and in alcohol. It is completely dissolved by nitric and hydrochloric acids with copious effervescence. Bismuth Subcarbonate responds to the reactions for bismuth and for carbonates.

" One Gm. of Bismuth Subcarbonate shows no more *chloride* than corresponds to 1 cc. of fiftieth-normal hydrochloric acid. Dissolve 3 Gm. of the salt in a sufficient quantity (about 4 cc.) of warm nitric acid, and pour the solution into 100 cc. of distilled water: a white precipitate is produced. Filter, evaporate the filtrate on a water bath to 30 cc., again filter the liquid, divide the latter filtrate into portions of 5 cc. each, and subject these several portions to the following tests: Mix one portion with an equal volume of diluted sulphuric acid: the liquid does not become cloudy (*lead*). Precipitate another portion with a slight excess of ammonia T.S.: the supernatant liquid does not exhibit a bluish tint (*copper*). Another portion is not immediately affected by barium nitrate T.S. (*sulphate*). In another portion, hydrochloric acid produces no precipitate which is insoluble in a slight excess of hydrochloric acid, but soluble in ammonia T.S. (*silver*). Boil 1 Gm. of Bismuth Subcarbonate with 20 cc. of a mixture of equal volumes of acetic acid and distilled water, cool the solution, and filter. Add 2 cc. of diluted hydrochloric acid, remove the bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*). Agitate about 0.05 Gm. of Bismuth Subcarbonate with 5 cc. of a solution of equal volumes of distilled water and ferrous sulphate T.S., and cautiously superimpose the mixture upon 5 cc. of concentrated sulphuric acid, no brownish-red zone forms at the line of contact of the two liquids (*nitrate*). The residue resulting from the ignition of 2 Gm. of Bismuth Subcarbonate does not respond to Bettendorf's Test for *arsenic.*

" **Assay.**—Dry about 1 Gm. of Bismuth Subcarbonate to constant weight at 100° C., weigh accurately in a tared porcelain crucible, ignite at a red heat, and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 90 per cent. of the original weight of Bismuth Subcarbonate taken.

" Preserve protected from light." *U. S.*

" A whitish, inodorous powder. Insoluble in *water;* soluble in *nitric acid* diluted with half its volume of *water.* Yields the *reactions* characteristic of bismuth and of carbonates. Yields when strongly heated from 89 to 91 per cent. of bismuth oxide. Yields no characteristic *reactions* for silver, lead, copper, calcium, selenium, tellurium, or chlorides, and not more than the slightest *reaction* for sulphates. *Arsenic limit* 2 parts per million. On mixing 0.02 gramme with 5 drops of *phenoldisulphonic acid,* adding after five minutes, 10 millilitres of *solution of ammonia,* filtering, washing the precipitate with *water* and adding *water* to the filtrate until it measures 100 millilitres, the color of the filtrate is not deeper than that obtained by similarly treating 0.00013 gramme of *potassium nitrate* (limit of nitrate). The solution obtained by exhausting 5 grammes with boiling *water* requires for neutralisation not more than 1 millilitre of *N/10 solution of sulphuric acid* (limit of alkaline carbonates)." *Br.*

Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9.5 per cent. of its weight in consequence of the escape of carbon dioxide, and is converted into the anhydrous trioxide, of a slight yellow color.

Uses.—Bismuth subcarbonate has the general properties of the insoluble salts of bismuth. (See under *Bismuthi Subnitras.*) In cases of *gastritis* and especially in *gastric ulcer* the fact that it acts as an alkali gives it preference over the subnitrate which is usualy acid in reaction. Loeper (*J. A. M. A.,* 1920, lxxv, 903) has found it valuable for the expulsion of *oxyuris vermicularis.* It is especially preferred over the subnitrate when large quantities are to be taken, as in röntgenography, because of its lower toxicity. For the purpose of rendering opaque to the X-ray the walls of the intestines it is the habit to give one to two ounces of an insoluble salt of bismuth. This quantity of the subcarbonate produces absolutely no disturbances of either the general system or the alimentary canal.

Dose, ten to thirty grains (0.65–2.0 Gm.).

BISMUTHI SUBGALLAS. U. S.

BISMUTH SUBGALLATE Bism. Subgal. [Basic Bismuth Gallate, Bismuth Oxygallate, Dermatol]

"Bismuth Subgallate is a basic salt of varying chemical composition which, when dried to constant weight at 100° C., yields, upon ignition, not less than 52 per cent. nor more than 57 per cent. of bismuth oxide [Bi_2O_3]." *U. S.*

Bismuthyl Gallate; Bismuth Monogallate; Dermatolum; Gallas Bismuthi Basicum; Gallate Basique de Bismuth, *Fr. Cod.;* Sousgallate de Bismuth, *Fr.;* Bismutum subgallicum, *P. G.;* Basisches Wismutgallat, *G.;* Galato basico de bismuto, *Sp.*

Preparation.—Bismuth Subgallate was originally prepared by Bley in 1841; Fischer again prepared and described it in 1891. It was introduced to the medical profession under the proprietary name of *Dermatol.* Its composition has been stated to be $C_6H_2(OH)_3.COOBi(OH)_2$. F. T. Greene proposes the following process: Normal bismuth nitrate, 1 oz. av.; glacial acetic acid, 2 fl. oz. or q. s.; gallic acid, 250 grains. Dissolve the normal bismuth nitrate in the glacial acetic acid; add a pint of water. If bismuth salts should precipitate, add more glacial acetic acid until clear. Filter off impurities. Dissolve the gallic acid in a pint of warm water; mix the solutions; allow the precipitate to subside; decant; wash by decantation with warm water until washings no longer show acid reaction. Dry at 100° C.; rub to powder. See *Ph. Rund.,* 1896, 85; *Ph. Ztg.,* 1901, 1033.

Description and Physical Properties.—"An amorphous, bright yellow powder. It is odorless and tasteless, and is stable in the air. Bismuth Subgallate is practically insoluble in water, alcohol and ether. It is readily dissolved with decomposition by warm, moderately dilute hydrochloric, nitric or sulphuric acid, insoluble in very dilute mineral acids. It is readily dissolved by solutions of alkali hydroxides, forming a clear, yellow liquid, which rapidly changes to a deep red.

"When heated to redness, Bismuth Subgallate at first chars, leaving finally a yellow residue, which is blackened by hydrogen sulphide T.S. A solution of this residue in a slight excess of warm nitric or hydrochloric acid produces a white turbidity when added to twenty-five volumes of distilled water. Agitate thoroughly about 0.1 Gm. of Bismuth Subgallate with an excess of hydrogen sulphide T.S., filter, boil the filtrate to remove the dissolved gas, cool, and add one drop of ferric chloride T.S.: a blue-black color is produced.

"Shake 1 Gm. of Bismuth Subgallate with 20 cc. of alcohol for one minute, filter, and evaporate the filtrate to dryness on a water bath: not more than 0.005 Gm. of residue remains (*free gallic acid*). Boil 1 Gm. of Bismuth Subgallate with 20 cc. of a mixture of equal parts of acetic acid and distilled water, cool the solution, and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*). Mix thoroughly about 0.05 Gm. of Bismuth Subgallate with 5 cc. of diluted sulphuric acid and 5 cc. of ferrous sulphate T.S., filter the mixture, and carefully superimpose the filtrate, without mixing, on 5 cc. of concentrated sulphuric acid, in a test tube: no brownish-red zone forms immediately (*nitrate*). Ignite 3 Gm. of Bismuth Subgallate in a porcelain crucible, cool, and cautiously add, drop by drop, just sufficient nitric acid to dissolve the residue when it is warmed. Evaporate the solution to dryness, again ignite, and cool. Cautiously dissolve this residue in just sufficient nitric acid by the aid of gentle heat, concentrate the solution to about 4 cc., pour it into 100 cc. of distilled water, filter, evaporate the filtrate on a water bath to 20 cc., again filter, and divide this filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper or silver* under *Bismuthi Subcarbonas.* The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subgallate, as described in the following test, meets the requirements of Bettendorf's Test for *arsenic.*" *U. S.*

Uses.—Bismuth subgallate was originally introduced into medicine as a substitute for iodoform in the treatment of *eczema* and other skin diseases and in surgical dressings. It does not, however, act like iodoform, and is only a feeble germicide. It resembles closely in all its medicinal activities the older insoluble preparations of bismuth, than which it is, however, thought by some practitioners to be more astringent, and therefore preferable in *diarrhea;* otherwise its rank in internal medicine is precisely that of the subnitrate.

Dose, seven to thirty grains (0.45–2.0 Gm.).

BISMUTHI SUBNITRAS. U. S., Br.

BISMUTH SUBNITRATE Bism. Subnit. [Basic Bismuth Nitrate, Bismuth Oxynitrate]

"Bismuth Subnitrate is a basic bismuth nitrate of varying chemical composition, which, when dried for twenty-four hours over sulphuric acid, yields upon ignition not less than 79 per cent. of bismuth oxide [Bi_2O_3]." *U. S.* "Bismuth oxynitrate, $BiONO_3,H_2O$, may be obtained by the interaction of bismuth nitrate and water." *Br.*

Subnitrate of Bismuth; Bismuthum Album, *Br.* 1864; Bismuthyl Nitrate; Magistery of Bismuth; White Bismuth; Nitras Bismuthi Basicus, Magisterium Bismuthi, Subazotas (s. Subnitras) Bismuthicus; Azotate (sous) de Bismuth, *Fr. Cod.;* Sous-nitrate de Bismuth, *Fr.;* Bismutum subnitricum, *P. G.;* Basisches Salpetersaures Wismutoxyd, Basisches Wismutnitrat, Wismutsubnitrat, *G.;* Nitrato basico di bismuto, *It.;* Nitrato (sub) bismutico, Magisterio de bismuto, *Sp.*

A process for bismuth subnitrate is no longer official in either the U. S. or Br. Pharmacopœias. In the U. S. formula of 1870 bismuth was dissolved in nitric acid added to a solution of sodium, carbonate, the resulting precipitate dissolved in nitric acid and precipitated with ammonia water, the object of this repeated precipitation being to get rid of arsenic which often contaminates metallic bismuth. The former British process (1867) dissolved purified bismuth in nitric acid, concentrated the solution by evaporation and poured it into a large volume of distilled water collecting the consequent precipitate. For details of these methods see *U. S. D.*, 19th edition, p. 242.

A. de Schulten obtained *crystallized bismuth subnitrate,* $5Bi_2O_3.5N_2O_5.9H_2O$, by dissolving 50 Gm. of bismuth subnitrate in 50 cc. of nitric acid (sp. gr. 1.2) and adding 300 cc. of water while stirring; the crystals which are produced are pressed between folds of filter paper and dried. (*Chem. News,* 1904, 87.) *Bismuth trinitrate,* the salt which is formed by dissolving metallic bismuth in nitric acid, forms colorless crystals of the formula, $Bi_3NO_3.5H_2O$, which are soluble in glycerin and acids but are changed by water to the insoluble subnitrate. This salt was at one time used for medicinal purposes but has been almost completely abandoned. Bismuth nitrate was used by Balmanno Squire dissolved in glycerin, under the name of *Glycerole of Nitrate of Bismuth.* W. W. Moorhead prepares it by taking two troyounces of crystalline bismuth nitrate and dissolving in sufficient glycerin to make eight fluidounces. No heat should be used. This preparation can be diluted with an equal bulk or less of water, or one part can be added to forty-eight of water without precipitation, but one part to twelve, eight, or six of water soon precipitates. (*A. J. P.*, 1877, p. 98.)

Description and Physical Properties.—"A white, slightly hygroscopic powder. Bismuth Subnitrate is practically insoluble in water, insoluble in alcohol, but is readily dissolved by hydrochloric or nitric acid. Bismuth Subnitrate responds to the reactions for bismuth and for nitrates. When heated to redness, it evolves brown vapors of nitrogen oxides, leaving a yellow residue. When brought in contact with moistened blue litmus paper, Bismuth Subnitrate shows a slightly acid reaction.

"Boil 1 Gm. of Bismuth Subnitrate with 20 cc. of a mixture of equal volumes of acetic acid and distilled water, and cool: a clear solution should result. Add 2 cc. of diluted hydrochloric acid, remove the bismuth by the addition of hydrogen sulphide, boil the mixture, and filter: the filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*zinc, iron, alkali earths or alkalies*). Boil about 0.1 Gm. of the salt with 5 cc. of sodium hydroxide T.S.: no odor of ammonia is perceptible nor does the vapor turn moistened red litmus paper blue. One Gm. of the salt shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid. The residue resulting from the ignition of 2 Gm. of the salt meets the requirements of Bettendorf's Test for *arsenic.* Add 3 Gm. of Bismuth Subnitrate to 3 cc. of warm nitric acid: no effervescence occurs (*carbonate*), and no residue remains (*insoluble foreign salts*). A white precipitate is produced when this solution is poured into 100 cc. of distilled water. Now filter, evaporate the filtrate on a water bath to 30 cc., again filter the liquid, and divide the new filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper, sulphate or silver* under *Bismuthi Subcarbonas.*

"**Assay.**—Dry about 1 Gm. of Bismuth Subnitrate over sulphuric acid for twenty-four hours, weigh accurately in a tared porcelain crucible, ignite at red heat, and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 79 per cent. of the original weight of Bismuth Subnitrate taken.

"Preserve protected from light." *U. S.*

"A white, inodorous, microcrystalline powder, with not more than a slight action on *litmus.* Yields the *reactions* characteristic of bismuth and of nitrates. Yields when strongly heated, from 79 to 82 per cent. of bismuth oxide. Yields no characteristic *reactions* for silver, lead, copper, calcium, selenium, or tellurium, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic* limit 2 parts per million." *Br.*

For examination of commercial bismuth subnitrate by Curtman, see *A. J. P.*, 1896, 422; *Ph. Era,* 1896, 43; also a paper by F. A. Upsher Smith (*P. S.*, 1900, 15).

Bismuth subnitrate is incompatible with potassium iodide (slowly forming a brick-red bismuth iodide) and with alkaline bicarbonates.

Uses.—The almost complete insolubility of the bismuth subnitrate has led to the belief that it is incapable of being absorbed from the gastrointestinal tract, but a number of chemists have found traces of bismuth in the urine and in various internal organs after its oral exhibition. It is evident, therefore, that it may be slowly absorbed from the bowels, but apparently unlimited quantities can be given by the mouth without enough of the metal being absorbed to produce any sign of bismuth intoxication. Although serious symptoms have been reported from the ingestion of doses of two ounces of bismuth subnitrate administered for röntgenographic purposes, it has been shown that the condition was due to the formation of nitrous acid in the intestinal tract and not to the bismuth. When applied to raw surfaces, however, the subnitrate of bismuth undergoes some chemical change and sufficient of the metal may be absorbed to cause fatal poisoning The symptoms of bismuth poisoning which have followed the surgical use of bismuth subnitrate are as follows: There appears first a bluish line on the edges of the gum which spreads and becomes darker in color until the whole tongue and pharynx are almost black. There also develops ulcerative stomatitis with salivation, nephritis, vomiting, and in some cases mental disturbances and methemoglobinemia. The mortality in this poisoning is high. (See David and Kauffmann, *J. A. M. A.*, 1909, lii.)

The insoluble salts of bismuth because of their heaviness, as well as their insolubility, tend to cling to any surface to which they are applied; therefore when they are brought in contact with the mucous membrane they form over it a coating which protects the membrane against the action of a local irritant. Chiefly because of this protective action, but probably also in part because of a feeble antiseptic influence, the insoluble salts of bismuth are of great value in the treatment of all forms of *catarrh,* especially of the acuter types, such as *rhinitis, gastritis,* or *enteritis.* Although in no proper sense an antemetic, in cases of *vomiting* dependent upon irritation of the stomach, bismuth by its sedative influence upon the mucous membrane may relieve the emesis. In the same way in cases of *gastric ulcer* it assuages the pain by protecting the ulcerated surface from the irritant secretion of the stomach. When used in cases of gastric disease it should be given when the stomach is empty, preferably in the form of a suspension or as a dry powder, so that it will spread of itself out over the mucous membrane of this organ before it is carried out into the duodenum, by peristaltic movements. On the other hand, in *enteritis* it should be given after meals. The bismuth salts are also useful as topical applications in the treatment of *coryza, gonorrhea, dysentery,* and similar conditions. For this purpose from 1 to 4 per cent. should be suspended by means of mucilage of acacia. When administered by mouth in fairly large quantities bismuth often causes blackish discoloration of the stools. As a form of suspension of bismuth subnitrate less liable to produce bismuth poisoning, it has been suggested to use 20 Gm. of bismuth subnitrate, 70 Gm. of liquid petrolatum, and 10 Gm. of petrolatum. This preparation is not readily absorbed and may be sweetened and flavored and used for a bismuth meal for radioscopy.

As was first shown by Kocher the insoluble salts of bismuth possess considerable antiseptic virtues when applied to raw surfaces. The subnitrate of bismuth was at one time largely, and it still is to a less extent, used as a dusting powder in various *wounds* and *ulcers.* In 1908 Beck (*J. A. M. A.,* March 14, 1908) described the favorable results following the injection of a mixture containing one part of bismuth subnitrate and two parts of petrolatum into the chronic *fistulas* of *bone tuberculosis.* His method has been followed by a large number of surgeons with mostly favorable results, although in a number of cases the injection of the bismuth paste into abscess cavities has led to bismuth poisoning. This mixture is known as *Beck's bismuth paste,* and it is important that it shall be sterile. Under the title of *Bipp* an ointment of bismuth and iodoform was introduced as a wound dressing during the World War and has been largely used by English surgeons. The formula recommended by Morison is iodoform 440 Gm., bismuth subnitrate 220 Gm., petrolatum 220 Gm.

The bismuth and petrolatum are sterilized by dry heat at temperature of 120° C. for half an hour, the bismuth after cooling is mixed with the iodoform in a mortar that has been sterilized by means of boiling water and solution of formaldehye. The petrolatum is added to the mixture at a temperature of 90° C. and thoroughly mixed. Care must be taken in sterilizing that the temperature does not rise to high, otherwise nitrous fumes will be evolved.

For further information on this paste see *J. A. M. A.*, 1918, lxxi, 300.

The acidity of bismuth subnitrate sometimes leads to the development of explosive mixtures in prescriptions containing sodium bicarbonate.

Dose, five to thirty grains (0.32–2.0 Gm.).

BISMUTHI SUBSALICYLAS. U. S. (Br.)

BISMUTH SUBSALICYLATE Bism. Subsalicyl.

[Basic Bismuth Salicylate, Bismuth Oxysalicylate]

"Bismuth Subsalicylate is a basic salt of varying chemical composition, which, when dried to constant weight at 100° C., yields upon ignition not less than 62 per cent. and not more than 66 per cent of bismuth oxide [Bi_2O_3]." *U. S.* "Bismuth Salicylate, or oxysalicylate, $BiOC_7H_5O_3$, may be obtained by the interaction of bismuth hydroxide and salicylic acid." *Br.*

Bismuthi Salicylas, *Br.;* Bismuth Salicylate; Bismuthyl Salicylate, Bismuth Oxysalicylate; Salicylate Basique de Bismuth, *Fr. Cod.;* Sous-salicylate de Bismuth, *Fr.;* Bismuthum subsalicylicum, *P. G.;* Basisches Wismutsalicylat (salicylsaures Wismutoxyd,) Wismutsubsalicylat, *G.;* Salicilato de bismuto, *Sp.*

Preparation.—This salt is a bismuthyl salicylate of somewhat variable composition, the bismuth oxide resulting from its ignition being about 64 per cent. Samples which show a higher percentage than this either contain bismuth subnitrate or hydroxide. It may be made by Wolff's process, by diluting a glycerin solution of crystallized bismuthous nitrate with one or two parts of water, and decomposing this with a concentrated aqueous solution of sodium salicylate, then washing the precipitate well with hot water and carefully drying. Another method for its preparation will be found in *A. J. P.,* 1891, 401. Fischer and Grützner (*A. Pharm.,* 1894, 680) object to the variable composition of commercial bismuth salicylate, and recommend the following process for making a basic salt of constant composition. Crystallized bismuth nitrate is dissolved in four times its weight of diluted acetic acid, the solution diluted with about forty times its weight of water, and the bismuth precipitated as hydroxide by ammonia water. The precipitate is washed and mixed with the molecular proportion of salicylic acid. After heating on a water bath, a magma of crystals of basic bismuth salicylic is formed; these are drained and dried. B. Fischer recommended the following process: one molecule each of salicylic acid and freshly precipitated bismuth hydroxide are heated together with the necessary amount of water on the water bath; filter, collect and dry the residue at 80° to 100° C. on porous tiling. (*Ph. Centralh.*, 1895, 92, 169.) Duyk perpares bismuth salicylate as follows: 100 Gm. of pure bismuth subnitrate are treated for one or two days with one liter of water, to which 50 Gm. of ammonia water have been added. After shaking sufficiently the subnitrate is completely changed into an oxide, which is collected and carefully washed with water. This oxide, after expression, is heated, under constant stirring, with 25 Gm. powdered salicylic acid on a water bath. After the union has been effected, the salicylate is washed and dried at a gentle heat. (*B. S. Ph. Br.*, 1891.) Thibault prefers the use of crystallized bismuth nitrate and solution of sodium hydroxide to precipitate the bismuth hydroxide. (*Bull. Soc. Chem.*, xxv, No. 16.) The bismuth is combined not only with the hydrogen of the carboxyl group but with the hydrogen of the phenolic group as well. Hence it is not a true salt of bismuth and salicylic acid and the name *salicylated bismuth* would be more correct.

Description and Physical Properties.—"A white, or nearly white, amorphous or crystalline powder. It is odorless, and is stable in the air. Bismuth Subsalicylate is practically insoluble in cold water. Upon prolonged boiling with water, a portion of the salicylic acid passes into solution with the formation of a more basic bismuth salicylate. When treated with a slight excess of warm nitric or hydrochloric acid, it is decomposed, a flocculent white precipitate of salicylic acid separating.

"When heated, Bismuth Subsalicylate at first chars, and above 300° C., leaves a yellow residue, which is blackened by hydrogen sulphide. This residue responds to the reactions for bismuth. Agitate about 0.1 Gm. of Bismuth Subsalicylate with a solution of five drops of ferric chloride T.S. in 10 cc. of distilled water: a deep violet-blue coloration is produced.

"Agitate 1 Gm. of Bismuth Subsalicylate with 20 cc. of chloroform, filter the liquid, and evaporate the filtrate to dryness: not more than 0.005 Gm. of residue remains (*free salicylic acid*). Ignite 3 Gm. of Bismuth Subsalicylate in a porcelain crucible, cool and cautiously add, drop by drop, just sufficient nitric acid to dissolve the residue when it is warmed. Pour the acid solution into 100 cc. of distilled water, filter, evaporate the filtrate on a water bath to 30 cc., again filter, and divide the filtrate into portions of 5 cc. each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* under *Bismuthi Subcarbonas.* Boil 1 Gm. of Bismuth Subsalicylate with 20 cc. of a mixture of equal parts of acetic acid and distilled water, cool the solution, and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture, and again filter: the latter filtrate on evaporation and ignition leaves not more than 0.005 Gm. of residue (*alkalies or alkali earths*). Triturate about 0.05 Gm. of Bismuth Subsalicylate with 0.1 Gm. of sodium salicylate and 5 cc. of distilled water, and superimpose the mixture upon 5 cc. of concentrated sulphuric acid, no pink or brownish-red zone is observed at the line of contact (*nitrate*). The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subsalicylate, as described in the test below, meets the requirements of Bettendorf's Test for *arsenic.*

"**Assay.**—Dry about 1 Gm. of Bismuth Subsalicylate to constant weight at 100° C., and weigh accurately. Ignite in a porcelain crucible, and, after cooling, add 5 cc. of nitric acid, drop by drop, to the residue, warming until solution has been effected. Evaporate this solution to dryness, and carefully ignite it at red heat and weigh the resulting bismuth oxide. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 62 per cent. and not more than 66 per cent. of the original weight of Bismuth Subsalicylate taken.

"Preserve protected from light." *U. S.*

"A white or nearly white amorphous powder, insoluble in *water.* Yields the *reactions* characteristic of bismuth. When shaken with diluted *T. Sol. of ferric chloride* a violet color is produced. Yields not more than the slightest characteristic *reaction* with the copper test for nitrates. *Arsenic limit* 2 parts per million. When 5 grammes are shaken with 50 millilitres of *ether*, the ethereal solution filtered off and evaporated to dryness leaves not more than 0.005 gramme of residue (limit of free salicylic acid). Yields when strongly heated from 62 to 65 per cent. of bismuth oxide. Free from the impurities indicated under 'Bismuthi Carbonas.'" *Br.*

Uses.—Bismuth subsalicylate differs from the subnitrate in that it exercises a distinctly antiseptic as well as protective effect in the bowels It is used to a considerable extent in the treatment of chronic *intestinal catarrhs* and subacute *diarrheas* with marked tendency to intestinal fermentation; also as a local antiseptic remedy for *wounds* and various inflamations of the mucous membrane.

Dose, from ten to twenty grains (0.65–1.3 Gm.), every four to eight hours.

BISMUTHUM.

BISMUTH

$Bi = 208.0$

Etain de Glace, Bismuth, *Fr.;* Wismuth, Wismut, *G.;* Bismuto, *It., Sp.*

Bismuth occurs usually in the metallic state, occasionally as a sulphide (*bismuthite*) or a telluride, and rarely as an oxide. It is found largely in Saxony, Schneeberg being the chief point of production. It has been found, mainly as telluride of bismuth, in Colorado with gold and silver ores. Small quantities have been found in Utah and Wyoming. It has also been discovered in southern Australia, from whence a quantity of it has been sent into commerce. It is obtained almost entirely from native bismuth ore, which is heated by means of wood or charcoal, whereby the metal is fused, and separated from its gangue. Most of the bismuth of commerce formerly came from Germany and Austria, but it is now largely mined in Bolivia and Australia. The bismuth ore from South America is said to be naturally free from arsenic, and to be therefore preferable for pharmaceutical purposes.

As the production of bismuth in the world far exceeds the demand, there is no regular American production, much of that which accompanies the gold and silver in the ore being allowed to go to waste in the slag.

Bismuth was first recognized as a metal by Agricola in 1520. Before that period it was confounded with lead. It is brittle, pulverizable, brilliant metal, of a crystalline texture, and of a white color with a slight reddish tint. Its crystals are rhombohedral, but with an angle of 87° 40′, which makes it difficult to distinguish them from cubes, in which the angle would be 90°. Indeed, many books still refer to it as cubical in form. It undergoes but a slight tarnish in the air. Its sp. gr. is 9.8 (*B. P.*, 1885, purified 9.38), melting point 264° C. Its most notable property is the ease with which it forms easily fusible alloys used as valves in fire sprinkler systems, for wood cuts, etc. *Wood's metal* consists of cadmium, tin, lead and bismuth and melts at 68° C. *Rose's metal* consists of lead, tin and bismuth and melts at 79° C. *Newton's alloy* also contains lead, tin and bismuth and melts at 95° C. *Lipowitz's alloy* has the same elements present as Woods metal but in slightly different proportions and softens at 60° C. At a high temperature, in close vessels, bismuth volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a faint blue flame, forming an oxide of a yellow color. This is the *trioxide*, or *bismuthous oxide*, and consists of two atoms of bismuth and three of oxygen. There is another compound of bismuth and oxygen consisting of two atoms of the former and five atoms of the latter, which is called *bismuthic oxide*, Bi_2C_5. It is obtained in the form of a hydroxide by boiling bismuth nitrate in solution of potassium hydroxide, washing the precipitate, and mixing it while moist with solution of potassium hydroxide into which chlorine is passed. A mixture of bismuthous and bismuthic oxides is precipitated, from which the former is separated by digestion with nitric acid. The hydroxide remaining, when washed and dried, is in the form of a red powder, which gives up its water at 130° C., and at a higher heat loses oxygen. Bismuth is acted on feebly by hydrochloric acid, but violently by nitric acid, which dissolves it with a copious liberation of red fumes. Sulphuric acid, when cold, has no action on it, but at a boiling heat effects its solution with the liberation of sulphurous acid. As it occurs in commerce, it is generally contaminated with other metals, among which are arsenic in minute quantity, traces of silver, cadmium, nickel, lead and iron, and sometimes a very small proportion of thallium. Claassen has found in so-called "purissimus" bismuth, lead, copper, and iron, and in one sample of bismuth, sold as suitable for scientific purposes, he obtained from 500 grammes 10 grammes of lead chloride. (*Ap. Ztg.*, 1891, p. 121; see also *Chem. News*, 1892, lxv, 28.) It may be purified from all contaminating metals by dissolving the bismuth of commerce in diluted nitric acid, precipitating the clear solution by adding it to water, and reducing the white powder thus obtained with black flux. The same precipitate is obtained by adding ammonia to the nitric solution; if the supernatant liquid in blue, the presence of copper is indicated; if the precipitate is yellowish, iron is present.

Uses.—Bismuth is not used in medicine in an uncombined state, but is employed pharmaceutically to obtain bismuth subcarbonate, subnitrate, subgallate, subsalicylate and other medicinal preparations formed from this metal. In the arts its oxychloride is used to form a cosmetic for the complexion, called *pearl white*, and the metal is an ingredient of the best pewter.

Recently the bismuth salts have been found to be highly toxic to certain protozoa and some of them have been used in syphilis and other protozocal infections (see *Luatol*, Part II).

Although enormous doses of the official salts of bismuth can be given by mouth without injurious effect, when introduced into the circulation the metal is an active poison. Soluble salts of bismuth when injected into the blood stream in sufficient doses stimulate the central nervous system, giving rise to convulsions and depress the circulation. Non-fatal doses cause violent inflammation of the excreting organs, including the kidney, salivary glands and intestine. The type of poisoning seen in human beings from the medicinal use is described under bismuth subnitrate.

BITUMEN SULPHONATUM. N. F.

SULPHONATED BITUMEN Bitum. Sulph.

"Sulphonated Bitumen contains not less than 2.5 per cent. of ammonia, not more than 8 per cent. of ammonium sulphate, and not less than 10 per cent. of total sulphur." *N. F.*

Ichthyol; Ammonii Sulphoichthyolas; Ammonium Sulphoichthyolate; Ammonium Ichthyolsulphonate; Ammonium Ichtholicum; Sulpho-ichthyolas Ammonicus, Ictiol, *Sp.*

There has long been used in medicine a group of tarry preparations obtained by sulphonating bituminous shale. The original preparation of this type was prepared from the distillate of a peculiar deposit found in the Tyrol and was known under the name of *ichthyol.* This distillate when treated with sulphuric acid gave a compound known as *ichthyol-sulphonic* acid which was neutralized before being used, generally with ammonium.

A large number of more or less similar preparations are upon the market. These are described in Part II under the group of *Ichthyol substitutes.* Thompson (*Proc. N. Y. State Pharm. Assoc.,* 1920, p. 198) finds the proportion of sulphur in these substances to vary from 4.5 to 11 per cent.

Description and Physical Properties.—"A viscous fluid obtained by the destructive distillation of certain bituminous schists, sulphonating the distillate and neutralizing the product with ammonia. Sulphonated Bitumen is reddish brown to brownish black in color, with a strong characteristic, empyreumatic odor. It is soluble in water and in glycerin, and is miscible with fixed oils and fats. It is partly soluble in alcohol or ether, and entirely soluble in a mixture of equal volumes of these solvents. An aqueous solution (1 in 10) may be faintly acid or faintly alkaline to litmus paper. The addition of hydrochloric acid to this solution precipitates a dark resinous mass which is soluble in ether.

"Upon boiling an aqueous solution with sodium hydroxide T.S., ammonia is evolved. Upon incineration, the ash of sulphonated bitumen does not exceed 0.5 per cent. Upon drying on a water bath to constant weight, sulphonated bitumen loses not more than 50 per cent.

"**Assay for Ammonia.**—Accurately weigh about 5 Gm. of Sulphonated Bitumen, dissolve in 100 cc. of water, transfer to a distillation flask, add an excess of sodium hydroxide solution and distil slowly; collect the distillate (about 50 cc.) in 15 cc. of normal sulphuric acid. When the distillation is completed, titrate the excess of sulphuric acid with tenth-normal sodium hydroxide, using methyl orange as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.001703 Gm. of NH_3.

"**Assay for Ammonium Sulphate.**—Accurately weigh about 1 Gm. of Sulphonated Bitumen, transfer to a 100 cc.-beaker and add 25 cc. of alcohol. Stir thoroughly, filter, and wash the filter with a mixture of equal parts of ether and alcohol until the washings are clear and colorless. Dry the residue on the filter at 100° C., cool, and wash the filter with 200 cc. of warm water slightly acidulated with hydrochloric acid. Determine the sulphate in the solution by precipitation with barium chloride T.S., and after washing, drying, igniting, and weighing, calculate the results to ammonium sulphate.

"**Assay for Total Sulphur.**—Dry about 1 Gm. of Sulphonated Bitumen, on a watch glass, to constant weight at 105° C. Pulverize the dried material and transfer about 0.5 Gm., accurately weighed, to a nickel crucible. Add about 9 Gm. of sulphur-free sodium peroxide, and mix thoroughly. Place the crucible carefully in a beaker containing cold distilled water which should reach about half way to the top. Ignite the dry mixture in the crucible by thrusting a red hot iron wire through a hole in the cover of the crucible. After complete combustion has taken place, tip the crucible and allow the fused mass to dissolve in the distilled water. Add hydrochloric acid in slight excess, heat to boiling and determine the sulphate in the solution by precipitation with barium chloride T.S., and after washing, drying, igniting, and weighing, calculate the results to sulphur. The total sulphur should not be less than 10 per cent." *N. F.*

The *sodium ichthyol* (*sodium sulphoichthyolate*) is a dark, tar-like substance of an alkaline reaction, perfectly soluble in water. Both preparations combine with fat and vaseline in all proportions. According to Baumann, they have a great affinity for oxygen, and are powerful reducing agents. The ichthyol sulphonates of lithium, zinc, mercury, sodium and calcium have also been prepared.

Odorless ichthyol has been made by treating ichthyol with hydrogen dioxide. It is questionable, however, whether the removal of the odorous constituents does not impair the therapeutic activity of the ichthyol.

Uses.—Ichthyol was formerly attributed with almost magic alterative action upon the skin, but is much less highly esteemed today than two decades ago. Such therapeutic value as it possesses appears to be due to a combination of four properties; it is feebly irritant and therefore acts as a local stimulant, tending to improve the peripheral circulation. It possesses reducing properties similar to those of sulphur; it appears to penetrate the skin with comparative readiness; it is feebly antiseptic. Abel (*Cb. B.,* 1893, xiv, p. 413) finds that pure ichthyol kills staphylococci in five minutes but will not destroy the typhoid bacillus even after an hour; that one to two thousand inhibits the growth of streptococci but it requires 5 per cent. to prevent the growth of staphylococci.

Sulphonated bitumen has been used in a very large variety of skin diseases, but is especially prized in the treatment of *acne* and *furunculosis.* It has been used also as a mild counterirritant in *rheumatic* conditions and *sprained joints.* The use of it in *lymphadenitis* is based upon nothing more tangible than a forlorn hope of the desperate. It has also been occasionally prescribed internally as an expectorant.

Dose, from two to five grains (0.12–0.3 Gm.).

Off. Prep.—Collodium Bituminis Sulphonati, *N. F.;* Petroxolinum Bituminis Sulphonati, *N. F.;* Unguentum Bituminis Sulphonati, *N. F.*

BOLDUS. N. F.

BOLDO [Boldo Leaves]

"Boldo is the dried leaf of *Boldu Boldus* (Molina) Lyons (Fam. *Monimiaceæ*). Boldo contains not more than 2 per cent. of its stems or other foreign organic matter and yields not more than 6 per cent. of acid-insoluble ash." *N. F.*

Peumus Boldus Mol. is an evergreen shrub, frequenting the meadows of the Andes in Chili, where its yellowish-green fruit is eaten, its bark used in tanning, and its wood is employed in charcoal making.

Description and Physical Properties.—"*Unground Boldo.*—Broadly ovate or oval, 3 to 7 cm. long and 1 to 4 cm. wide, the base varying from rounded to very slightly indented, the apex rounded or slightly notched, the margin entire and sharply revolute; thick, coriaceous, rigid and brittle; pale green to brownish green, papillose, roughened on both surfaces, the principal veins coarsely reticulate, impressed above, sharply prominent underneath; the petiole stout and rigid, 1 to 5 mm. long, reticulate. Odor peculiar, when crushed very strong, disagreeable, and somewhat like that of oil of chenopodium; taste bitter, warm and pungent, camphoraceous and slightly terebinthinate.

"*Structure.*—Upper epidermis with papilla-like excrescences; a well marked hypodermis; palisade layer with frequent cells containing volatile oil; spongy parenchyma with many large cavities containing cystoliths of calcium carbonate; numerous oil secretion cells; prominent, radial, collateral fibro-vascular bundle in midrib; occasional groups of radiating 1-celled, thick-walled hairs, stomata numerous on the lower surface and hairs somewhat smaller." *N. F.*

The principal constituent of boldo leaves is a volatile oil of which they yield about 2 per cent. This oil has a specific gravity of between 0.915 to 0.945 and a boiling point between 175° and 250° C.; it may be either laevo- or dextro-rotary. It gives a green color with ferric chloride and is composed chiefly of terpenes and containing also some unknown oxygenated bodies. Apparently it is related chemically to the oil of chenopodium. (See *Schim. Rep.*, Oct., 1907.) A peculiar alkaloid, *boldine*, has been found in them by Bourgoin and Verne (*J. P. C.*, 4e sér., xvi, 191), and a glucoside, *boldoglucin*, $C_{30}H_{52}O_8$, a thick syrupy liquid, by P. Chapoteaut. (*C. R. A. S.*, xcviii, 1052.)

Uses.—According to Sigismond Pascaletti (*Terapia Moderna*, 1891), boldine when injected hypodermically paralyzes both the motor and sensory nerves, and also attacks the muscle fibers. When given internally in toxic dose it produces great excitement, with exaggeration of the reflexes and of the respiratory movements, increased diuresis, cramps, disorders of coördination, convulsions, finally death from centric respiratory paralysis, the heart continuing to beat long after the arrest of respiration, finally stopping in diastole. Boldine has been widely used in veterinary medicine as a remedy for *jaundice*. It has also been used in man in the treatment of hepatic affections, in *doses* of one one-hundredth to one-twentieth of a grain (0.0006-0.003 Gm.) in conjunction with calomel. Boldoglucin is said to act on the lower animals as a narcotic, and has been given by Réne Juranviller in *doses* of one to three grains (0.06–0.2 Gm.) in diseases of the liver. Fifteen minims (0.9 cc.) of the oil of boldo cause in man some warmth in the epigastrium; thirty minims (1.8 cc.), much gastric irritation, with pain and vomiting, and passage of urine smelling strongly of the oil. Dujardin-Beaumetz finds the oil useful in *genito-urinary inflammations* in doses of five drops (0.25 cc.) (*B. G. T.*, March, 1875). In France boldo has been employed as a tonic in *chronic hepatic torpor* and in *hepatitis*, and Fedeli (*Il Policlinico*, 1907) reports favorable results in the treatment of *cholelithiasis*.

According to A. T. De Rochebrune (*Toxicol. Africaine*, i, 1897), the tree *Monimia rotundifolia*, of Australia, contains an abundant volatile oil, an alkaloid, and a glucoside, which are very similar to, if they are not identical with, those obtained from the *Boldo*, and may be substituted for the latter in therapeutics.

Dose, five to ten grains (0.3–0.6 Gm.).

Off. Prep.—Fluidextractum Boldo, *N. F.*

BRAYERA. N. F. (Br.)

BRAYERA Brayer. [Kousso, Cusso]

"Brayera is the dried panicle of the pistillate flowers of *Hagenia abyssinica* (Bruce) Gmelin (Fam. *Rosaceæ*). Brayera contains not more than 10 per cent. of staminate flowers or other foreign organic matter and yields not more than 5 per cent. of acid-insoluble ash. Reject stems over 3 mm. in diameter and all binding material before powdering or using the drug." *N. F.*

"Kousso consists of the dried panicles of pistillate flowers of Brayera anthelmintica, *Kunth.*" *Br.*

Cusso, *Br.*; Kooso; Kusso; Koso Flores; Brayeræ Flores; Flos Cousi; Cousso, *Fr. Cod.*; Kousso, *Fr.*; Flores Koso, *P. G.*; Kosoblüthen, Kosso, Kuso, Cusso, *G.*; Kousso, Cosso, *It.*; Flor de Couso, *Sp.*

Hagenia abyssinica Willd. (*Brayera anthelmintica* Kunth) is a handsome monœcious tree, native to northeastern Africa and found growing on the tableland of Abyssinia at an elevation from 3000 to 8000 feet. It is cultivated by the natives of that country as a worm remedy. The plant attains a height of 18 to 38 feet and is characterized by possessing large, imparipinnate leaves with lanceolate, serrate leaflets, paniculate inflorescences and achenial fruits. The panicles which bear pistillate flowers are alone recognized as of medicinal value. Each of these consists of a repeatedly branched axis covered with brown hairs, the branches arising from the axils of bracts and dotted with orange-colored glandular hairs which darken with age. Arising from the smaller branches are numerous, short pedicelled flowers, each of which consists of a greenish epicalyx of 5 segments, a calyx of 5 sepals, a white caducous corolla of 5 slender petals, abortive stamens, and 2 carpels with ovaries enclosed in a receptacular cup.

Corolla and abortive stamens are wanting in the dried flowers. The drug is brought from Abyssinia packed in boxes, reaching Europe chiefly by way of Aden and Bombay. The fruit of the tree is said to be used as an anthelmintic in Abyssinia, but Dragendorff failed to detect any active principle in it. It is stated that in Abyssinia, honey gathered directly after the flowering season from beehives in gardens planted with kousso plants, is used in doses of a teaspoonful as a tænicide.

The drug of commerce consists either of cylindrical rolls or flattened bundles of the dried pistillate inflorescences tied with the stem of a rush or, as it is chiefly seen at present, of dried flowers mixed with fragments of leaves (*loose kousso*). The male flowers are frequently collected, when the general color of the mass is greenish-yellow or light brown; sometimes the female flowers constitute the bulk of the drug, which then has a distinct reddish tint, and is often known in commerce as *red kousso*. The male flowers are often found mixed with the female flowers, when loose (not in bundles), as high as 12 per cent. of this adulteration having been noticed by Meyer and Sandlund. (*Ph. Ztg.*, 1893, No. 99.)

Description and Physical Properties.—"*Unground Brayera.*—In reddish brown rolls or flattened bundles 25 to 50 cm. long, or occurring more or less loose and stripped from the larger portions of the panicles. Panicle branches cylindrical, somewhat flattened, longitudinally furrowed or wrinkled, externally light brown to yellowish, tomentose, glandular; cork brownish, bast- and wood-fibers yellow, fibro-vascular bundles in wedges, pith large and yellowish brown; nodes distinct, each with a scar or branch and subtended by a sheathing bract; internodes mostly 1 to 2 cm. long. Flowers subtended by 2 ovate, reddish, pubescent and glandular bracts; pedicel short; calyx turbinate, pubescent below, subtended by 4 or 5 rigid, spreading, obovate, purple-veined bractlets which are persistent and elongated in fruit, alternating with and larger than the 5 usually shriveled, reflexed calyx lobes; petals 5, caducous, and usually absent in the drug; carpels 2; styles exserted, stigmas broad and hairy with prominent papillæ; fruit an ovoid achene about 2 mm. in diameter, enclosed by the remains of the calyx. The staminate flowers are greenish yellow, with about 20 fertile stamens. Odor slight; taste bitter.

"*Powdered Brayera.*—Light brown or reddish brown; numerous simple, non-glandular, straight or curved hairs, up to about 1 mm. long, with thick, strongly lignified walls, usually enlarged at the base; glandular hairs with 1- to 3-celled stalks, the glandular head unicellular or consisting of 1 or 2 pairs of cells; tracheæ up to 0.050 mm. wide, spiral, annular, scalariform or with bordered pores; fibers long, thick-walled, strongly lignified and with numerous, simple, oblique pores; parenchyma of pith more or less lignified and with large simple pores; fragments of epidermal tissue from the bracts and calyx with elliptical stomata, the latter up to 0.030 mm. long; groups of thin-walled, somewhat branching, parenchyma cells with large intracellular spaces; tissue from the inner surface of the pericarp consisting of numerous elongated, porous, strongly lignified cells; calcium oxalate in rosettes up to 0.040 mm. in diameter; occasionally fragments of tissue containing prisms of calcium oxalate, the latter about 0.015 mm. long; pollen grains few, nearly spherical, from 0.025 to 0.040 mm. in diameter, with three pores. The larger branches of the panicles with simple, non-glandular hairs up to about 5 mm. long; tracheæ up to 0.125 mm. wide and rosettes of calcium oxalate up to about 0.075 mm. in diameter." *N. F.*

"Usually in more or less cylindrical rolls from three to six decimetres long, composed of reddish panicles of pistillate flowers. Panicles much branched, the branches arising from the axils of large sheathing bracts; more or less covered with hairs of glands. Flowers numerous, small, shortly stalked, mostly unisexual, with two roundish, membranous, veined bracts at the base of each. Calyx with reddish veins, hairy externally, and consisting of two alternating whorls each of five segments, the inner whorl being curved inwards over the young fruit and shrivelled. No marked odor; taste bitter and acrid." *Br.*

As the medicine, from its high price, is apt to be adulterated, it should be procured in the unpowdered state, in which the botanical characters of the flower will sufficiently attest its genuineness. It has a fragrant balsamic odor, and the taste, slightly perceptible at first, becomes in a short time somewhat acrid and disagreeable.

Analyzed by Wittstein, it was found to contain, in 100 parts, 6.25 of bitter acrid resin, 24.40 of tannin, 15.71 of ash, besides fatty matter, liguin and chlorophyll. Bedall, of Munich, determined the bitter acrid resin of Wittstein is equivalent to the *tæniin* of Pavesi, and gave it the name of *kosin.* Commercial kosin is a mixture of two inactive yellow, crystalline substances α- and β-kosin. Leichsenring (*A. Pharm.*, 1894, 50) has re-examined kousso, and finds an inactive crystalline principle to which he gives the name *protokosine,* and an amorphous substance, *kosotoxin,* which he considers the active principle of the drug; the latter is a yellowish powder, fusing at 80° C., and not obtainable in a crystalline state. It is easily soluble in alcohol, ether, benzene, carbon disulphide, and insoluble in water. Kosotoxin, which occurs in the unripe fruit as well as the flowers, is hydrolyzed by alkalies into kosin.

Kosotoxin is stated to be a derivative of trimethylphloroglucin, which indicates a relationship between the principles of cusso and of aspidium (see *Aspidium*).

There are also stated to be present an amorphous glucoside *coussin,* $C_{26}H_{41}O_5$, and a crystalline principle *cosine,* $C_{22}H_{32}O_7$, which upon hydrolysis yields isobutyric acid and an unidentified body.

Kosidin and *kosoin* have also been reported present, as well as an iron greening tannin and traces of oxalic, acetic and valeric acids.

Uses.—Kousso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Brayer, a French physician practising in Constantinople, published a treatise on it at Paris in 1823. It was in his honor that Kunth adopted the generic title of the plant. Much attention has been attracted to this valuable medicine, and trials made with it have proved its efficacy in the destruction and expulsion of the *tape-worm.* Its effects when taken internally are not very striking. In the ordinary dose it sometimes produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the bowels, though this effect is not always produced. It appears to act exclusively as a poison to the worms, and has been found equally effectual in both kinds of *tape-worm.* The medicine is taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water, the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce (15.5 Gm.), which may be diminished one-third for a child of twelve years, one-half for one of six years, and two-thirds for one of three years. Should the medicine not act on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be usually sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce (31 Gm.).

So far as we know, no cases of human poisoning by kousso or its active principle are on record, but it has been found by Rochebrune to be capable of causing centric convulsions in the lower animals.

Dose, from two to four drachms (8–15 Gm.).

Off. Prep.—Infusum Brayeræ, *N. F.*

BROMUM. N. F.

Bromine

"It contains not less than 99 per cent. of Br. (79.92) and not more than 1 per cent. of Cl." *N. F.*

Bromum; Brominium; Brome, *Fr. Cod.;* Bromum, *P. G.;* Brom, *G.;* Bromo, *It., Sp.*

Bromine is an elementary body, possessing many analogies to chlorine and iodine. It was discovered in 1826 by Balard, of Montpellier, in the bittern of sea salt works, in which it exists as a magnesium bromide. Since then it has been found in the waters of the ocean, in certain marine animals and vegetables, in various aquatic plants, in numerous salt springs, and in the mineral kingdom and in the coal gas liquor of the Paris gas works. In the United States it was first obtained by Silliman, who found it in the bittern of the salt works at Salina, in the State of New York. It is now obtained in largest amount from the brines of Ohio, Pennsylvania, Michigan, and West Virginia. The chief works are located at Parkersburg and Mason City, W. Va.; Pomeroy, Ohio, and Midland County, Mich. The chief source of bromine in Europe is the potash mines at Stassfurt, Germany, where the magnesium bromide remains as a residue after extraction of the potassium salts.

The method of separating the bromine from these various salt liquors is first to concentrate the solution by evaporation which causes the less soluble chlorides and sulphates to crystallize out. The bittern which is left—containing some residue of chlorides with varying percentages of sodium, calcium or magnesium bromides—is treated with an oxidizing agent, either manganese dioxide or potassium chlorate, thereby causing the liberation of chlorine, which in turn decomposes the bromides liberating the bromine which is removed by a current of hot air. In Germany the bittern is decomposed in a continuous process by a current of chlorine and hot steam, the liberated bromine dissolving in the solution from which it may be removed by distillation. In Michigan the bittern is decomposed by an electrolytic process.

The crude bromine obtained in this manner is often contaminated with bromine chloride (BrCl). It is purified by treating it with ferrous bromide thereby liberating the chlorine according to the following reaction:

$$FeBr_2 + 2BrCl = FeCl_2 + 2BrCl_2$$

Recently a vessel has been fitted out for the purpose of recovering bromine from sea-water, and is now (1925) making its first voyage for that purpose. More than two-thirds of the bromine of commerce is used for the manufacture of bromides for medicinal use, and for photography; the remainder is used for aniline colors.

Properties.—The National Formulary gives the following description: "Bromine is a heavy, dark, brownish-red, mobile liquid, evolving, even at ordinary temperatures, reddish fumes, highly irritating to the eyes and lungs, and having a peculiar, suffocating odor, resembling that of chlorine. Specific gravity: about 3.1 at 25° C. Boiling point: about 63° C. One cc. dissolves in about 90 cc. of water; it is freely soluble in alcohol, ether, chloroform, or carbon disulphide.

On exposure to air it volatilizes. It destroys the color of solutions of litmus or indigo, and imparts a yellow color to starch T.S. Add 1 cc. of bromine to 50 cc. of sodium hydroxide T.S.; it combines to form a permanently clear liquid, without the separation of oily drops (*organic bromine compounds*). Shake

10 cc. of a saturated aqueous solution of Bromine with a slight excess of reduced iron until it becomes nearly colorless, filter the liquid and add 1 cc. of ferric chloride T.S. and 1 cc. of starch T.S.; it does not assume a blue color (*iodine*).

Assay.—"Dissolve 10 Gm. of potassium iodide in 25 mils of distilled water, introduce the solution into a 100 cc. measuring flask, stopper and determine accurately the weight of the flask and its contents. Add about 1 Gm. (or 0.3 cc.) of Bromine to the contents of the flask, determine its exact weight and then fill the flask to the mark with distilled water and titrate 25 cc. of this solution with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate used corresponds to 0.007992 Gm. of Br. or 0.003546 Gm. of Cl. Each gramme of Bromine (containing not more than 1 per cent. of chlorine) corresponds to not more than 126.7 cc. of tenth-normal sodium thiosulphate.

"Preserve Bromine in glass-stoppered bottles in a cool place, each bottle being enclosed in a larger vessel with the space between being filled with some substance capable of absorbing and combining with any vapors which might escape." *N. F.*

Bromine congeals at -7° C. and at -20° C. becomes a hard, brittle, crystalline solid, having a dark leaden color, and a luster nearly metallic. It boils at about 63° C., forming a reddish vapor resembling that of nitrous acid, and of the sp. gr. 5.54. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapor.

Bromine is sparingly soluble in water to which it communicates an orange color, more soluble in alcohol, and still more so in ether, chloroform, and carbon disulphide. By the aid, however, of potassium bromide, it may be dissolved to any desirable extent in water. Its alcoholic and ethereal solutions lose their color in a few days and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, destroys the color of indigo sulphate, and decomposes organic matters. Its combination with starch has a yellow color. It corrodes the skin and gives it a deep yellow stain. Bromine is intermediate in its affinities between chlorine and iodine, since its combinations with metals are decomposed by chlorine, while, in its turn, it decomposes those of iodine. It forms acids which are analogous in properties and composition to the corresponding acids of chlorine and iodine.

Uses.—In concentrated solution bromine is a powerful caustic and germicide. Its disinfectant properties appear to be somewhat inferior to those of chlorine; according to Koch, a 2 per cent. solution destroys the anthrax spores in twenty-four hours and Miquel gives the antiseptic limit as 1 in 1600. At one time it was employed internally in *scrofulous* and *syphilitic diseases*, but there is no reason to believe that it exercises any different effect upon the system from the salts of hydrobromic acid, and it has been entirely abandoned as an internal remedy. In dilute solution, from 10 to 40 minims to a pint of water, it is occasionally employed as a wash for ulcers but has no advantage over other disinfectants. It was a highly lauded remedy for *hospital gangrene*, which before the days of antiseptic surgery was a frequent condition in military hospitals.

In overdoses bromine is a corrosive poison. About an ounce ingested caused violent inflammation of the lips, mouth, tongue, and esophagus, with incessant burning pain, followed, in two hours and a half, by prostration, ending in death. (Snell, *N. Y. Journ. of Med.*, Sept., 1850.) In a vaporized state, it was one of the poison gases used in the trench warfare in France and Belgium in the European War. The best antidote, according to Alfred Smee, is ammonia, given largely diluted and mixed with sweet oil. Thiosulphates are also antidotes and an effective mask to prevent the inhalation of the fumes is provided by covering the mouth and nose with gauze which has been recently saturated with an aqueous solution of sodium thiosulphate.

BRYONIA. N. F.

BRYONIA [Bryony]

"Bryonia is the dried root of *Bryonia alba* Linné or of *Bryonia diocia* Jacquin (Fam. *Cucurbitaceæ*). Bryonia contains not more than 2 per cent. of foreign organic matter." *N. F.*

The bryonias are climbing or trailing herbs with rough, hairy leaves. The *white bryony* (*B. alba*) is found in central and northern Europe and the red bryony (*B. dioica*) in England. The fruit of the latter is red and that of the white bryony is black. The term "black bryony" has been applied to a very different plant, *Tamus communis* L. which belongs to the *Dioscoreaceæ.* The berries of this plant are irritant poisons and, according to Coutagne, cause in animals paralysis and convulsions (see *Rep. Pharm.*, Nov., 1884; *P. J., Jan.*, 1903). The *B. americana* Lam. of the West Indies and the *B. africana* Thumb. are said to be employed in their respective countries as hydragogue cathartics.

The flowers of the *B. alba* are monoecious and the berries black. The *B. dioica* has dioecious flowers and scarlet berries.

The N. F. recognizes the root which it describes as:

Description and Physical Properties.—"*Unground Bryonia.*—Usually in circular or elliptical slices, from 1.5 to 10 cm. wide and from 3 to 15 mm. thick; the edges light gray or yellowish, rough and striate, the cut surface white or faintly yellow, showing a thin cortex and a wood with numerous projecting, collateral fibrovascular bundles arranged in concentric zones; fracture short and mealy, whitish internally. Odor faint but distinct and characteristic; taste bitter and nauseous.

"*Powdered Bryonia.*—Light yellow; starch grains simple, rounded or 2- or more compound, from 0.004 to 0.024 mm. in diameter, frequently with a central cleft; tracheæ from 0.35 to 0.250 mm. wide, reticulate or with bordered pores; large yellow cork cells.

"Add sulphuric acid to the powdered drug; it becomes reddish-brown and then brownish-purple." *N. F.*

The substance known as *bryonin,* according to Power and Moore (*Tr. Chem. Soc.,* 1911, xcix, 937), is not a pure principle but a mixture of a glucoside and an alkaloid neither of which is physiologically active. Jensen (*P. J.,* 1915, xcv, p. 641) confirms the inertness of bryonin but describes a second glucoside, *bryonidin,* which exercises a paralytic effect upon the central nervous system. Bryonia also contains a dark brown resin known as *bryoresin* to which its purgative properties are probably due.

Uses.—Bryonia is an active irritant hydragogue cathartic. In a number of cases it has produced serious or even fatal poisoning. Vomiting and purging have been commonly present, but in some cases there has been no diarrhea. Giddiness, delirium, and dilated pupils, coupled with fall of the bodily temperature, imperceptible pulse, cold perspiration, and other manifestations of collapse, are the usual symptoms. Eighty minims (5 cc.) of the homeopathic tincture caused very serious but not fatal poisoning. (For cases, see *B. M. J.,* 1883, ii, 1067; *T.G.,* ii, 35.) The fresh root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication.

Bryonia has real value as a hydragogue cathartic but is little used at present for this purpose. By the medical sect who call themselves eclectics it was highly esteemed in the treatment of various pectoral conditions as *bronchitis, whooping-cough, pleurisy* and *pneumonia* and also in various other inflammatory disorders. It is still used to a certain extent by the regular profession for similar purposes.

Dose, ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Tinctura Bryoniæ, *N. F.*

BUCHU. U. S. (Br.)

BUCHU

"Buchu is the dried leaf of *Barosma betulina* (Thunberg) Bartling et Wendland, or of *Barosma crenulata* (Linné) Hooker, known in commerce as Short Buchu; or of *Barosma serratifolia* (Curtis) Willdenow, known in commerce as Long Buchu (Fam. *Rutaceæ*). Buchu contains not more than 8 per cent. of its stems and not more than 2 per cent. of other foreign organic matter." *U. S.* "Buchu Leaves are the dried leaves of Barosma betulina, *Bart. and Wendl.*" *Br.*

Buchu Folia, *Br.;* Folia Bucco, Folia Diosmæ, s. Barosmæ; Feuilles de Bucco (Booko, Buchu), *Fr.;* Buckublätter, Buccoblätter, *G.*

The leaves of the official and other *Barosmas* (so named from βαρύς, heavy, and ὀσμή, odor), and of some *Agathosmas,* are collected by the Hottentots, who value them on account of their odor ,and under the name of *bookoo* or *buchu,* rub them, in the state of powder, upon their greased bodies.

The medicinal species of Barosma are all erect, slender shrubs with opposite leaves, dotted with conspicuous pellucid oil glands, smooth, angular, purplish branches, often of a purplish color, white flowers, and a fruit of five erect follicles. They are chiefly distinguished by their leaves.

Barosma betulina is a small shrubby plant indigenous to Cape Colony. The leaves are collected while the plant is in flower and fruit, then dried. *B. serratifolia* is a well-developed shrub growing in the mountains of the southwest of Cape Colony. The leaves of both of these plants are collected in the Cape Colony district of South Africa when the plants are in the flowering or fruiting condition. About 90 per cent. of the supply used in the United States comes from Cape Town, South Africa. The other 10 per cent. comes through London. According to Schimmel and Co., the buchu plant thrives best in a very sandy soil, but it is rather difficult to cultivate as the cuttings do not root readily. The buchu of commerce always contains more or less foreign material, such as stems, twigs and old worthless leaves, and the U. S. Pharmacopœia has wisely limited the amount of such admixture to 10 per cent.

Barosma crenulata (L.) Hook, has leaves opposite, ovate or obvate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and stand solitarily at the end of short, lateral leafy shoots.

The non-official species, which have been seen in European markets occasionally, are said to be used in South Africa as substitutes for the official buchu; they are:

Barosma Eckloniana Bartl., a plant which has been considered to be only a variety of *B. crenulata,* has leaves which are rounded at the base, shorter and proportionately wider than those of *B. crenulata* and also grow upon pubescent shoots.

The leaves of *Barosma venusta* Ecklon and Zeyher, which are said to have appeared in the London markets, are readily distinguished by their being very much smaller than those of *B. betulina,* which they otherwise resemble.

Barosma pulchellum (L.) Bartl. and Wendl.—The leaves closely resemble those of the *B. betulina,* being ovate instead of obovate, that is, they are wider at the base. Their odor is quite different, strongly recalling that of citronella, and Schimmel and Company have demonstrated the presence in them of citronellal.

Under the name of *Karoo buchu,* in 1904 the leaves of the *Diosma succulenta* L., var. *Bergiana* H. and S., appeared in London; they are small and heath-like, thick, obtuse, and slightly recurved, and yielded to C. E. Sage (*C. D.*, lxv, 506, 787) a small semi-solid volatile oil having the odor of peppermint. Another buchu, which has appeared on the market, has leaves resembling very closely those of *Barosma scoparia* E. and Z. (*Pref. & Ess. Oil Rec.*, 1914, p. 375.)

Buchu is subject to many adulterations both by the leaves of other species of the genus as well as more distantly related leaves. The most important of these adulterations are as follows: *Psoralea obliqua* E. Mey, or *P. bracteata* (*P. J.*, 1910, pp. 69 and 464), and *Empleurum serrulatum* Ait. The leaves of the latter have a more acrid taste, are lanceolate or narrowly linear, about 4 cm. in length, yellowish-green and very acute at the summit. They furthermore acrid taste, are lanceolate or narrowly of the teeth. (For description of many other adulterants, see Holmes, *P. J.*, 1910, lxxxv, p. 464.)

Description and Physical Properties.—"*Unground Short Buchu.*—Rhomboidally oval or obovate, from 9 to 30 mm. in length and from 4 to 20 mm. in breadth; apex obtuse or rounded and sometimes recurved, base wedge-shaped or obtuse, margin finely dentate, glandular punctate, with an oil gland at the base of each tooth, papillose, longitudinally striate beneath, coriaceous and with a petiole about 1 mm. in length; color bright green to yellowish-green, occasionally olive-gray; odor aromatic, and mint-like; taste camphoraceous.

"*Unground Long Buchu.*—Linear-lanceolate from 12 mm. to 4 cm. in length and from 4 to 10 mm. in breadth; apex acute, somewhat rounded; margin sharply serrate. Otherwise resembles Short Buchu.

"*Structure.*—Cuticle thick, somewhat uneven and striated; hairs few, simple, 1-celled, non-lignified, up to 0.145 mm. in length (Short Buchu), or 0.180 mm. in length (Long Buchu). Stomata absent on the upper surface, numerous on the lower surface, broadly oval, up to 0.040 mm. in length and surrounded by from 4 to 6 neighboring cells; epidermal cells with inner walls mucilaginous and containing colorless sphero-crystal aggregates of hesperidin which strongly polarize light, the latter form giving a brilliant display of colors; a single row of large hypodermal cells beneath the upper epidermis containing mucilage and frequently brownish, feather-like crystal aggregates; palisade cells in a single row below the mucilage cells, and bordering a loose mesophyll, the cells containing numerous plastids and a few rosette aggregates of calcium oxalate; oil cavities occurring mostly near the margin of the leaf, circular in outline and containing globules of oil. Fibro-vascular bundles of midrib and larger veins collateral, in crescent-shaped groups, composed chiefly of tracheæ, sieve tubes and non-lignified fibers and separated by collenchyma from the lower epidermis.

"*Powdered Buchu.*—Light green; elements of identification are epidermal cells containing sphero-crystals or crystal aggregates of hesperidin, rosette aggregates of calcium oxalate from 0.015 to 0.030 mm. in diameter, a few simple hairs, lower tissue with numerous stomata, oil secretion cavities and oil globules, and fragments of the fibro-vascular bundles." *U. S.*

"From twelve to twenty millimetres long, rhomboid-obovate, dull yellowish-green, rigid, cartilaginous when slightly moist. Surface glabrous, bearing small scattered prominences; margin usually sharply denticulate, apex blunt and recurved. Oil glands visible in the leaf, especially in epidermis cells containing yellow especially near the margin. Transverse section exhibits in epidermis cells containing yellow sphero-crystals; inner walls of these cells thick and rich in mucilage. Odor and taste strong and characteristic." *Br.*

The leaves of *B. betulina* constitute the *short buchu* or *round buchu,* while those of *B. serratifolia* are the *long buchu* of commerce. The leaves of *B. crenulata* are at present comparatively infrequent in commerce, the parcels usually consisting of those of one of the other species almost unmixed. The species can be recognized by the characters already given.

Buchu leaves yield a volatile oil with a peppermint-like odor. The amount of oil present in the short buchu ranges from 1.5 to 2 per cent., but in the long buchu is much less, usually not over 1 per cent. (*Schim. Rep.*, Oct., 1893). This oil on chilling deposits a stearopten which is known as *Barosma camphor* or *diosphenol* (it is, however, said not to occur in the oil from *B. serratifolia*). This substance, which composes about 30 per cent. of the oil, forms crystals which have a melting point of 82° C. and boil at 232° C. with partial decomposition. The residue of the oil after extraction of the diosphenol contains a hydrocarbon, $C_{10}H_{18}$, and a ketone, $C_{10}H_{18}O$, which is probably laevogyrate menthone. Spica (*P. J.*, 1885) found in the leaves of the *B. crenulata,* from which the oil had been extracted, a solid principle *diosmin* which is considered now to be the same as hesperidin found in orange peel. His results were confirmed by Shimoyama (*A. J. P.*, 1888) who also has prepared several derivatives of diosphenol. The yield of ash varies, according to the researches of H. W. Jones (*P. J.*, ix, 673), from 4.69 to 4.40 in *B. betulina,* 4.32 to 5.39 in *B. crenulata,* 5.03 to 5.22 in *B. serratifolia;* the ash itself was remarkable as containing a great deal of manganese.

Uses.—The activity of buchu depends upon the volatile oil, which is eliminated by the kidneys. Under its action there is no marked increase in the amount of the urine, but the oil affects very decidedly the mucous membrane of the genito-urinary tract, perhaps by virtue of some antiseptic power. The remedy is useful in diseases of the urinary organs, such as *gravel,* chronic *cystitis, urethritis* and *diseases of the prostate.* It should not be given when the inflammation is severely acute. An infusion (one ounce in a pint of boiling water) may be given in the dose of one to two fluidounces (30–60 cc.), but the best preparation is the fluidextract.

Dose, one-half to one drachm (2.0–3.9 Gm.).

F.;* Elixir Buchu et Potassii Acetatis (from Elixir of Buchu), *N. F.;* Fluidextractum Buchu Compositum, *N. F.*

BUTEÆ GUMMI. Br.

BUTEA GUM [Bengal Kino]

"Butea Gum is the inspissated juice obtained from incisions in the stem of Butea frondosa, *Roxb.*" *Br.*

For description and uses, see under butea seeds.

BUTEÆ SEMINA. Br.

BUTEA SEEDS

"Butea Seeds are the seeds of Butea frondosa, *Roxb.*" *Br.*

The *Sacred Tree, Butea frondosa* (Fam. *Leguminosæ*), enters largely into the religious rites of the Hindoos. Its red flowers are offered at the bloody sacrifice of the goddess Kali. Its leaf with three spreading leaflets is supposed to represent the Hindoo deity, and furnishes platters used when the Hindoo boy becomes of age.

Butea gum, which has sometimes been mistaken for African kino, is the concrete juice of the *Butea frondosa* Roxb., or *Dhak-tree* of Hindostan, and also to some extent of *B. superba.* The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red color when examined in small fragments by transmitted light; in some specimens the tears are much paler than described, and of a very beautiful ruby tint. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The solubilities and reactions of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, and sand, etc., it contains from 20 to 60 per cent. of kinotannic acid besides considerable gum and insoluble substances. It is, however, very seldom imported into England, and never, at present, into this country.

Butea gum occurs in "small irregular shining fragments, very dark ruby color, thinnest flakes transparent when examined by transmitted light. Partially soluble in *water;* about 40 per cent. soluble in hot *alcohol* (90 per cent.), the solution being scarcely colored. No odor; taste astringent. Free from corky or woody particles. On keeping, the fragments may become dull and blackish." *Br.*

"In India and the Eastern Divisions of the Empire, Butea Gum may be employed in making the official preparations for which kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used." *Br.*

The British Pharmacopœia describes the seeds as "flat, reniform, from twenty-five to thirty-eight millimetres long, sixteen to twenty-five millimetres wide, and one and a half to two millimetres thick. Testa thin, glossy, veined, wrinkled, dark reddish-brown. Cotyledons large, leafy, yellow. Faint odor; taste slightly acrid." *Br.*

For a description of the seeds see also *Ph. Rev.,* 1896, 232.

The seeds contain about 18 per cent. of fat and an equal amount of protein, but no principle has been found to which any therapeutic activity can be attributed. The gum contains from 15 to 60 per cent. of kinotannic acid.

Uses.—Butea gum is used for the same purposes and in the same doses as kino. The seeds have been used by the native practitioners in India as vermifuges against both the *tape worm* and the *round worm.* According to the *Pharmacographica Indica,* the infusion of three seeds exercises a laxative effect. Before being used, the seeds should be soaked in water and the integument carefully removed. The powdered dried kernels may be given in doses of ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Pulvis Buteæ Seminum, *Br.*

BUTYL-CHLORAL HYDRAS. Br.

BUTYL-CHLORAL HYDRATE

"Butyl-Chloral Hydrate, or trichlorbutylidene glycol, $C_4H_7Cl_3O_2$, is a crystalline hydrate obtained by adding water to the liquid butylchloral produced by the action of chlorine gas on aldehyde." *Br.*

Butylchloralum Hydratum, Chloralhydratum Butyli; Trichlorbutylidene Glycol; Hydrous Butyl Chloral; Croton Chloral Hydrate (wrongly so called); Chloralum Butyli Hydratum; Hydrate de Chloral Butylique, *Fr.;* Butylchloralhydrat, Trichlorbutylaldehydhydrat, *G.*

This substance was discovered by Krämer and Pinner, of Berlin, during an examination of the accumulated by-products of the chloral factory of Schering. It was named croton-chloral hydrate because it was believed to bear a relationship to crotonic acid, the peculiar acid of croton oil; this was subsequently disproved by Pinner, who showed that it belonged to the butyl series. (*B. Chem. G.,* vii, 1321, 1561.) It is made by passing dry chlorine through aldehyde cooled to –10° C. in an apparatus similar to that used in making chloral. Fractional distillation is resorted to, and the product boiling between 163° C. and 165° C. is reserved; this is butyl-chloral, a colorless oily fluid. The necessary amount of water is added, and butyl-chloral hydrate is obtained.

Properties.—Butyl-chloride hydrate occurs in the form of crystalline, micaceous scales of a pungent odor, sparingly soluble in water, freely soluble in alcohol, hot water, and glycerin, but insoluble, or nearly so, in chloroform, a property which may be employed to separate it from ordinary hydrated chloral. When treated with caustic alkalies it is converted into formic acid, potassium chloride, and allylene dichloride, $C_3H_4Cl_2$. The British Pharmacopœia describes it as "pearly-white, trimetric laminæ. Odor pungent but not acrid; taste acrid and nauseous. Melts at about 78° C. to a transparent liquid, which, on cooling, begins to solidify at about 71° C. Soluble in about 40 parts of *water,* and in less than 1 part of *glycerin* or of *alcohol* (90 per cent.). The aqueous solution is neutral or but slightly acid to *litmus.* When 0.5 gramme is gently warmed for a short time with 10 millilitres of *solution of sodium hydroxide,* 3 drops of *aniline* added and the mixture well shaken and heated to boiling, no odor of phenyl iso-cyanide is perceptible (absence of chloral hydrate)." *Br.*

Uses.—Butyl-chloral hydrate was proposed by Liebreich, in 1870, as a remedy in the treatment of *trigeminal neuralgia.* He states that a drachm (3.9 Gm.) of it causes deep sleep, accompanied by anesthesia of the head, with complete loss of irritability of the eyeball and of the trigeminal nerve. The circulation is kept up with great tenacity, and, if the dose has been large enough, death results from the arrest of respiration. These statements of Liebreich were contradicted by the research of J. von Mering and of H. W. Schmidt, who found that no anesthesia was produced unless sufficient doses were given to cause complete narcosis, and that the general course of the symptoms caused by the butyl-chloral hydrate was exactly parallel to that of those produced by hydrated chloral. But a number of observers have used butyl-chloral hydrate with asserted good results in *tic douloureux.* The relief obtained is, unfortunately, only temporary and palliative. The drug has been commonly administered in doses of from 5 to 20 grains (0.32–1.3 Gm.) in syrup. The safer plan is to give 5 grains (0.32 Gm.) every half hour until 30 grains (2.0 Gm.) have been taken or relief afforded. The original formula of Liebreich was: butyl-chloral hydrate 5 to 10 parts, glycerin 20 parts, distilled water 130 parts. Dose, half a flouidounce (15 cc.), followed in five minutes by a second dose, ten minutes later by a third dose, unless relief is afforded. That such medication is safe is not certain. For experiments in making and dispensing solutions of butyl-chloral hydrate, see *Proc. A. Ph. A.,* 1894, 578.

Dose, of British Pharmancopœia, from five to twenty grains (0.32–1.3 Gm.).

CACAO PRÆPARATUM. N. F.

COCOA [Prepared Cacao]

"Cocoa is a powder prepared from the roasted, cured kernel of the ripe seed of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*)." *N. F.*

Chocolat, *Fr.;* Schokolade, Kakao, *G.;* Cioccolata, *It.;* Chocolatl, *Mex.*

Theobroma Cacao L. is a handsome evergreen tree from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America. It is largely cultivated in all tropical countries, particularly in Guayaquil, Venezuela, Mexico, Trinidad, and the Philippines. It possesses alternate, elliptic-oblong, entire leaves and fascicles of small, rose-colored flowers, the latter appearing on the trunk and larger branches. The fruit is an oblong-ovate, ten-ribbed capsular nut, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cacao,* or *chocolate nuts,* of commerce. The cacao tree is usually cultivated in large estates, where it is grown in the shade of the banana or other large plant, and develops its pods from the stem continually, so that the harvest goes on all the time, although the product is greater in the spring and in the autumn. The pods are cut off, opened, and the beans contained in the glutinous sweet acid pulp are allowed to ferment, during which process the outer integument comes off easily. The beans are finally carefully dried, commonly in the sun, sometimes by means of a steam drying shed. If the sweating process is carried too far, or the beans during drying are wetted by rain, they blacken and are much lowered in value. These blackened beans are sometimes artificially whitened. Cacao beans have a slightly aromatic, bitter, oily taste, and, when bruised or heated, an agreeable odor. (See *Am. Drug.,* 1897, 311; also *Ph. Ztg.,* 1900, 756.)

The average of a number of analyses of raw beans gave H. Weigmann (*König's Nahrungs- und Genussmittel,* 3d ed., vol. i, 1019) water, 7.93 per cent.; nitrogenous matter, 14.19 per cent.; theobromine, 1.49 per cent.; fatty matter (cacao butter), 45.57 per cent.; starch and other carbohydrates, 22.92 per cent.; crude fiber, 4.78 per cent.; pure ash, 3.99 per cent.; sand, 0.62 per cent. The coloring matter is probably the result of chemical change, as the fresh seeds are white. Theobromine has been found also in the shells in the proportion of about 1 per cent. The latter impart to boiling water a taste analogous to that of chocolate, but weaker, and are used for making a table beverage. Chocolate is the solid substance expressed from the cacao bean after roasting. In Great Britain and the United States it is usually made, when pure, exclusively of the kernel of the cacao or chocolate nuts, which are first roasted, then deprived of their shells, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Sometimes rice flour or other farinaceous substance, with foreign fats, is added, but these must be considered as adulterations. In the compounded form known as sweet chocolate, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added; vanilla is a favorite addition in America, France, and Spain. The well-known confection known as *"milk chocolate"* contains either whole or skim milk powder in addition to the foregoing ingredients. The U. S. Department of Agriculture standards for cacao products are as follows:

"1. *Cocoa beans* are the seeds of the cacao tree, *Theobroma cacao,* L. 2. *Cocoa nibs, cracked cocoa,* is the roasted, broken cocoa bean freed from its shell or husk. 3. *Chocolate, plain chocolate, bitter chocolate, chocolate liquor, bitter chocolate coatings,* is the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, and contains not more than three (3) per cent. of ash insoluble in water, three and fifty hundredths (3.50) per cent. of crude fiber, and nine (9) per cent. of starch, and not less than forty-five (45) per cent. of cocoa fat. 4. *Sweet chocolate, sweet chocolate coatings,* is chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavoring materials, and contains in the sugar- and fat-free residue no higher percentage of either ash, fiber, or starch than is found in the sugar- and fat-free residue of chocolate. 5. *Cocoa, powdered cocoa,* is cocoa nibs, with or without the germ, deprived of a portion of its fat and finely pulverized, and contains percentages of ash, crude fiber, and starch corresponding to those in chocolate after correction for fat removed. 6. *Sweet cocoa, sweetened cocoa,* is cocoa mixed with sugar (sucrose), and contains not more than sixty (60) per cent. of sugar (sucrose), and in the sugar- and fat-free residue no higher percentage of either ash, crude fiber, or starch than is found in the sugar- and fat-free residue of chocolate."

Description and Physical Properties.—"*Cocoa:* Brownish-red; oil globules, protein grains and starch grains numerous, the latter, simple or compound and up to 0.012 mm. in diameter. Odor and taste, chocolate-like; free from sweetness.

"Extracted with ether, Cocoa yields not less than 18 per cent., or more than 25 per cent. of fat, and the fatty residue does not have a spicy odor or taste. The residue, insoluble in ether, shows not more than 3 per cent. of cocoa shells. Cocoa yields not more than 6 per cent. of crude fiber and not more than 15 per cent. of starch." *N. F.*

For Emminger's method of determining theobromine in cacao, see *P. J.*, 1896, 289.

Mixed with hot milk or water cocoa is much employed as a drink. It has the advantages over tea and coffee that it is less stimulating to the nervous system and contains some nutriment.

It is officially recognized because of its use as a flavoring agent.

Off. Prep.—Syrupus Cacao, *N. F.*

CACTUS GRANDIFLORUS. N. F.

CACTUS GRANDIFLORUS Cact. Grand.

[Night Blooming Cereus]

"*Cactus grandiflorus* is the fresh succulent stem of the wild growing *Selenicereus grandiflorus* (Linné) Britton et Rose (Fam. *Cactaceæ*)." *N. F.*

Night-blooming Cereus, Vanilla Cactus, Large-flowered Cactus, Sweet-scented Cactus, Queen of a Single Night, Cierge à grandes fleurs, *Fr.;* Königin der Nacht, *G.*

The night-blooming cereus, *Cactus grandiflorus* L. (*Selenicereus grandiflorus* (L.) Brit. and Rose), is a large fleshy shrub bearing terminal and lateral flowers with a diameter of from 8 to 12 inches which open at night, exhaling a vanilla-like odor during their few hours of bloom. It is a native of Jamaica but is frequently grown in hot houses for its showy flowers which, with their outer leaflets of dark brown shading through golden yellow into pure white in the center, are generally deemed among the most beautiful of flowers. The fleshy stems are armed with the spines which are characteristic of the cactus family.

For years most of the cactus supplies have been imported from Mexico. It has been shown that this drug was *Selenicereus spinulosus* Brit. and Rose, and that the genuine *Cactus grandiflorus* (*Selenicereus grandiflorus*), little of which was seen on the market, comes solely from Jamaica. The two can readily be distinguished by the ribs and spines; *S. spinulosus* stems usually possess 5 ribs and the spines are not acicular, in *S. grandiflorus* the stems have 7 to 8 ribs with acicular spines.

Description and Physical Properties.—"*Whole Cactus Grandiflorus.*—In pieces of varying length, from 1.5 to 4 cm. in diameter, and from 5 to 9 angled; the angles at intervals of about 2 cm. with tufts of from 9 to 12 acicular spines about 5 mm. in length, together with about the same number of bristles about 1 cm. in length; at irregular intervals branched roots sometimes present. It has a strong, herby odor; taste acidulous and mucilaginous.

"*Structure.*—The transverse section shows a central cylinder about 8 mm. in diameter and a spongy parenchyma containing large irregular fragments of tetragonal crystals, prisms and raphides of calcium oxalate." *N. F.*

Sultan (*A. J. P.*, 1891, p. 424) claimed to have isolated an alkaloid which he called *cactine* from this plant but subsequent chemists have been unable to confirm his statements. Sharp could find only inert resins.

Uses.—This drug has long been used in tropical America in the treatment of *dropsy.* It was brought into notice as a cardiac remedy by Rubini of Naples in 1896. Boynet and Boy-Teissier (*B. G. T.*, cxxi, p. 343) found that cactus increased the systolic contractions of the frog's heart, but Hatcher and Bailey (*J. A. M. A.*, 1911, lvi, p. 26), from experiments with carefully identified specimens as well as commercial preparations purporting to be of this drug, reached the conclusion that it was physiologically inert. Gordon Sharp (*Pract.* 1894, liii), from review of the literature and his own extensive clinical trials, reached the conclusion that the drug was therapeutically useless. Despite the vigor of the impugnments there still are many competent clinicians who continue to use the drug with apparent benefit in various neurogenic disturbances of *cardiac* rhythm such as seen in *Grave's disease, nicotinism, neuresthenia* and allied affections.

Dose, from five to fifteen grains (0.3–1 Gm.).

Off. Prep.—Tinctura Cacti Grandiflori, *N. F.*

CAFFEINA. U. S., Br.

CAFFEINE Caffein. [Theine]

"Trimethyl-xanthine [$C_5H(CH_3)_3O_2N_4.H_2O$.]" *U. S.* "Caffeine, $C_8S_{10}N_4O_2,H_2O$, is an alkaloid obtained from the dried leaves of Camellia Thea, *Link*, or from certain other plants." *Br.*

Trimethyl-xanthine, Methyl-theobromine; Caffeia; Theina; Caféine, *Fr. Cod.;* Coffeïnum, *P. G.;* Koffein, Kaffein, Thein, *G.;* Caffeïna, *It.;* Cafeina, *Sp.*

Caffeine was first discovered by Runge, and afterwards by Pelletier, Caventou and Robiquet. Strecker first proved it to be methyl-theobromine by making it from theobromine synthetically. (*Ann. Ch. Ph.*, cxviii, 170.) It is now recognized as an immediate derivative of xanthine, $C_5H_4O_2N_4$, being the trimethyl-derivative of the same, and it belongs to the purine group, of which xanthine is the dioxy-derivative. Emil Fischer has accomplished the conversion of uric acid, $C_5H_4O_3N_4$, into xanthine, and this into caffeine. Caffeine may be obtained from a number of plants including coffee, tea, cola, guarana, etc., but because tea leaves contain a much larger percentage of the alkaloid than does the coffee berry, and are frequently thrown into commerce in a damaged condition, unfit for use as a beverage, commercial caffeine is almost always prepared from them. The finely powdered unsalable material known as "tea sweepings" is also used. Dunstan and Shepheard (*J. Chem. S.*, 1893, 195) have thoroughly established the complete chemical identity of the alkaloids of tea and coffee by a study of a number of derivatives.

Caffeine may be isolated as follows: Exhaust powdered coffee or tea by boiling with two successive portions of water, unite the infusions, add lead acetate in order to precipitate various principles accompanying the caffeine, filter, decompose the excess of lead acetate in the filtered liquor by hydrogen sulphide (or sodium phosphate), concentrate by evaporation, and neutralize, with ammonia. The caffeine is deposited in crystals upon cooling, and may be purified by redissolving in water, treating with animal charcoal, and evaporating. H. Leuchsenring obtains caffeine by availing himself of its property of subliming unchanged by heat. He precipitates a concentrated decoction of coffee by a weak solution of lead acetate, filters, evaporates to dryness, mixes the residue with sand, and sublimes as in Mohr's process for procuring benzoic acid. (*A. J.*, xxxii, 25.) Paul and Cownley's process for estimating the caffeine in coffee is to mix finely powdered coffee with moist lime, and exhaust with alcohol by hot repercolation. The alcohol is evaporated off, and the residue mixed with water and a few drops of diluted sulphuric acid; the mixture is filtered, and the filtrate and washings, when cool, treated with chloroform to wash out the alkaloid; the chloroformic solution is evaporated in a tared dish, and the residue weighed as caffeine. (*P. J.*, 1887, p. 565.) Petit and Terrat subsequently found that the presence of lime or magnesia retards the extraction of the caffeine; they recommend direct extraction by chloroform containing a trace of water. (*J. P. C.*, 1896, 529.) A method of determining caffeine in either raw or roasted coffee, suggested by Fendler and Stüber (*Z. Nahr. Genuss.*, 1914, H.1), gives a very white and pure alkaloid. The method is as follows: The coffee is first extracted with chloroform. The residue from the chloroformic filtrate is taken up in hot water and treated with a solution of potassium permanganate in excess and the excess of manganese removed by adding a little solution of hydrogen dioxide, acidulated with acetic acid. After filtration the aqueous liquid is rendered alkaline and extracted with chloroform and the residue dried at 100° C. to constant weight. Power and Chestnut have developed an assay method yielding a very pure product. It is described in *J. Am. C. S.*, 1919, xli, 1298, 1307. For other methods see *A. J. P.*, 1892, 468, and 1893, 338; *Ap. Ztg.*, 1893, 132; *Ph. Era*, 1897, 391.

Caffeine is a feeble base, capable of forming definite compounds with mineral acids but not with organic acids; the latter, however, increase its solubility in water and other liquids. (See *Caffeina Citrata.*) The salts formed with mineral acids decompose when their solutions are evaporated. Caffeine is remarkable for containing a larger proportion of nitrogen than does almost any other proximate vegetable principle, in this respect equalling some of the highly animalized products.

Description and Physical Properties.—"White, flexible, silky, glistening needles, usually matted together in fleecy masses. It is odorless, has a bitter taste, and is efflorescent in dry air. One Gm. of Caffeine is soluble in 46 cc. of water, 66 cc. of alcohol, 50 cc. of acetone, 5.5 cc. of chloroform, 530 cc. of ether, and in 100 cc. of benzene, at 25° C. One Gm. is soluble in

5.5 cc. of water at 80° C., in 22 cc. of alcohol at 60° C., and in 22 cc. of boiling benzene.

"Caffeine rendered anhydrous by drying at about 100° C. melts between 235° and 237° C. A saturated, aqueous solution of Caffeine is neutral to litmus paper. Dissolve about 0.01 Gm. of Caffeine in 1 cc. of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath. On inverting the dish over a vessel containing a few drops of ammonia T.S., the residue acquires a purple color, which disappears upon the addition of solutions of fixed alkalies (*murexide reaction*). A saturated aqueous solution of Caffeine yields with tannic acid T.S., a precipitate which is soluble in an excess of the reagent, but no precipitate is produced by tenth-normal iodine unless the solution is first acidulated with hydrochloric or sulphuric acid.

"Caffeine loses not more than 9 per cent. when dried to constant weight at 80° C. Ash: not more than 0.05 per cent. The solution of 0.5 Gm. of Caffeine in 5 cc. of sulphuric or nitric acid is colorless or only faintly yellow (*readily carbonizable substances*). No precipitate is produced by mercuric potassium iodide T.S. in an aqueous solution of Caffeine (1 in 50) (*alkaloids*)." *U. S.*

The Br. Ph. describes it as "colorless, silky, acicular, inodorous crystals. Soluble in 80 parts of *water*, somewhat more soluble in *alcohol* (90 per cent.), readily soluble in *chloroform*, sparingly in *ether*. Melting point 235° C. Aqueous solution neutral to *litmus* and faintly bitter. Loses part of its water of crystallization on exposure to the air. Loss when dried at 100° C. not more than 8.5 per cent.; the dry alkaloid begins to volatilise at a slightly higher temperature and sublimes readily at about 180° C. A cold saturated aqueous solution is not precipitated by *N/10 solution of iodine*, or by solution *of potassio-mercuric iodide*, but gives a white precipitate with *solution of tannic acid*, soluble in excess of the reagent. 0.1 gramme dissolves without color in 1 millilitre of *sulphuric acid*, and also in 1 millilitre of *nitric acid*. When treated with a crystal of *potassium chlorate* and a few drops of *hydrochloric acid*, the mixture being evaporated to dryness in a porcelain dish, a reddish residue remains which becomes purple when exposed to the vapor of *solution of ammonia*." *Br.*

The apparent difference in solubilities of caffeine between the U. S. and British Pharmacopœias is due to the fact that the standard temperature of the U. S. is 25° C., and of the British 15.5° C. The U. S. solubilities are based upon the studies of Seidell (*J. Am. C. S.*, 1907, xxix, p. 1091).

The solubility of caffeine is increased by the presence of certain neutral salts as sodium benzoate, cinnamate, or salicylate. See *Caffeinæ Sodio-benzoas.*)

Uses.—There have been a few cases of poisoning by caffeine; a drachm of citrated caffeine swallowed by an adult was followed by burning in the throat, giddiness, faintness, nausea, tremor of the extremities, abdominal pain, mental distress, great cardiac oppression and finally collapse. Consciousness was not impaired and there was no headache until the patient began to recover. A decoction of 8 ounces of freshly roasted coffee, taken for the purpose of producing abortion, caused pronounced choreic tremors, great restlessness, quickened respiration, and rapid pulse, with very strong, even violent, heart beats. In doses of 3 to 5 grains caffeine produces in the healthy individual a peculiar wakefulness, with stimulation of the cerebrum, and some increase of the urinary secretion and force of the pulse. There is usually marked increase of the mental activity and of the capability for sustaining mental work. About two hours after the ingestion of 12 grains by Pratt, there were intense physical restlessness and mental anxiety, with obstinate sleeplessness, active and persistent thinking, general muscular tremulousness, and frequent urination.

Given in large dose to the lower animals, caffeine produces hurried respiration, restlessness, slightly lowered, followed by markedly elevated, temperature, tetanic and clonic convulsions, progressive paralysis, and finally death from paralytic arrest of respiration. The cause of the convulsions in mammals is not determined, but in the frog they are of spinal origin, for both Pratt and Le Blond have found that cutting of the cord does not arrest them below the point of section, while destruction of the cord (Pratt and Leven) prevents their development. It would appear, therefore, that caffeine acts upon the frog as a stimulant to the motor side of the spinal cord and a similar effect has been demonstrated in the human being by H. C. Wood, Jr. (*T. G.*, Jan., 1912.) In moderate doses, caffeine exercises a marked stimulating influence upon the muscle, increasing not only the irritability and contractile power of the muscle, but also the resistance to fatigue. Hyde, Root, and Curl (*A. J. Phys.*, 1917, xliii, p. 371) found that caffeine notably increased the muscular work as measured by the ergograph in human beings. When the drug is applied locally, in concentrated solution, it produces death of the muscle, with a condition simulating that of rigor mortis. In certain species of frogs a generalized rigidity of the muscles can be caused by the hypodermic administration of the drug, but it is improbable that sufficiently large quantities could be introduced into the system of any warm blooded animal to exercise this effect.

The effect of caffeine upon the circulation is less powerful than has been believed in the past. After moderate doses, there is generally, although not always, a slight rise in the blood pressure, with usually some slowing of the pulse. The rise in the blood pressure, as has been demonstrated by Sollmann and Pilcher (*J. P. Ex. T.*, 1911, iii, p. 19), is due solely to an increase in the vigor of the contraction of the heart, the blood vessels being usually somewhat dilated. After large doses the pulse becomes extremely rapid, apparently through a direct action upon the muscle of the heart, and the blood pressure shows a tendency to fall. The drop in the blood pressure after these large quantities appears to be due both to a widening of the vessels, and a diminution of the amplitude of the cardiac contractions.

In sufficient quantities, caffeine produces a very marked increase in the quantity of urine. Although the increase is more marked in the watery constituents, and the percentage of solid matter falls, the total quantity of solids eliminated in a given time is somewhat increased. The diuresis is accompanied with a marked widening of the renal vessels. This increase in the flow of urine appears to be due to a direct action on the renal epithelium, for Richards and Plant have shown (*J. P. Ex. T.*, 1915, vii, 485) that diuresis can be caused in the artificially perfused kidney without any acceleration of the blood flow.

The early belief that caffeine exercised some influence upon metabolism and the output of nitrogen has been entirely disproven. The only change in the amount or character of nitrogenous material in the urine is that which is due to the presence of caffeine itself, or its various methylization products in the body; it appears in the urine as a dimethyl- or monomethylxanthine. If the dose is small this reduction is complete, but after large quantities some of the drug may escape unaltered.

The dominant action of caffeine in the human being is upon the cerebrum. The experiments of Hollingworth (*T. G.*, Jan., 1912) have demonstrated that in those forms of psychological tests which involve purely intellectual processes there is a distinct increase in the rapidity and accuracy, an observation which is in entire harmony with the daily experience of millions of men. Not only is the mental activity temporarily stimulated, but the capability for prolonged work is also increased. After large quantities, this cerebral excitation shows itself in nervous restlessness, and a tendency to insomnia.

Although widely employed as a mental stimulant in daily life, caffeine is rarely used medically for this purpose, unless it be that its value in certain types of *headache* is associated with its action upon the cerebrum. Its most important medical uses are as a diuretic, and as a cardiac and respiratory stimulant.

As a diuretic, caffeine is of service, especially in the treatment of *dropsies*. When the dropsy is due to *nephritis* it must be used with some caution because of the possibility of an irritating action upon the diseased kidneys. Its value as a diuretic is lessened by its tendency to produce wakefulness, and because of this objection it has largely been displaced by the closely allied drugs, theobromine and theophylline. It is generally advisable, if using caffeine freely, not to administer the remedy in the latter part of the day. Those who have been habitual users of caffeinic beverages acquire a tolerance to the diuretic effects (see Myers, *J. P. Ex. T.*, 1924, xxxiii, p. 465) so that they require much larger doses or may refuse to respond altogether to the drug.

As a circulatory stimulant, caffeine is of little value as a cardiac tonic in cases of chronic *heart disease*, but finds its chief application in more or less acute *heart failure*, whether occurring during the course of a chronic cardiac condition, or as the result of the ingestion of the depressant *poisons*. Heathcote (*J. P. Ex. T.*, 1920, xvi, p. 327), finding that it actively dilates the coronary vessels, suggests its use in *angina pectoris*. In *surgical shock* the fact that it does not stimulate the vasomotor mechanism—which is generally believed to be the essential factor in these cases—makes it a remedy of only secondary value.

As a stimulant of the respiration it is a remedy of much usefulness, especially when used in connection with other agents of this class. It is more especially employed in cases of *narcotic poisoning*, such as morphine or chloral, in which it is useful, not only because of its direct action upon the respiratory center, but also because it counteracts, to some degree, the tendency to sleep.

Dose, one to five grains (0.065–0.32 Gm.).

Off. Prep.—Caffeina Citrata, *U. S.* (*Br.*); Caffeinæ Citras Effervescens (from Citrated Caffeine), *U. S.*; Pulvis Acetanilidi Compositus, *N. F.*; Caffeinæ Sodio-Benzoas, *U. S.*; Caffeinæ Sodio-Salicylas, *N. F.*; Sal Potassii Bromidi Effervescens Compositus, *N. F.*

CAFFEINA CITRATA. U. S. (Br.)

CITRATED CAFFEINE Caffein. Cit.

"Citrated Caffeine, when dried to constant weight at 80° C., contains not less than 48 per cent. nor more than 52 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4$]." *U. S.* "Caffeine Citrate, $C_8H_{10}N_4O_2,C_6H_8O_7$, is an unstable compound of Caffeine and Citric Acid." *Br.*

Caffeinæ Citras, *Br.*; Caffeine Citrate; Coffeinum Citricum; Citras Coffeicus; Citrate de Caféine, *Fr.*; Koffeïncitrat, Citronensaures Koffeïn, *G.*; Citrato cafeico, *Sp.*

"Caffeine, 100 grammes; Citric Acid, in powder, 100 grammes; Distilled Water, 16 millilitres. Mix the Caffeine with the Citric Acid, moisten the mixture with the Distilled Water, and dry on a water-bath with constant stirring." *Br.*

No formula is given in the U. S. X.

In this preparation Merson (*P. J.*, 1904, 8) prefers to mix the caffeine with the citric acid without the aid of a liquid; he uses a sieve, water bath, and granulating tray, and asserts that the process yields a superior product. It is not regarded by chemists as a chemical salt, but as a mechanical mixture of the two substances composing it. The British Pharmacopœia gives the following as its chemical formula: $C_8H_{10}N_4O_2,C_6H_8O_7$.

Description and Physical Properties.—"A white, odorless powder, having a slightly bitter, acid taste. One Gm. of Citrated Caffeine is soluble in about 4 cc. of warm water. On diluting the solution with an equal volume of water, a portion of the caffeine gradually separates, but redissolves on the further addition of water.

"The residue obtained in the assay when recrystallized from hot water and dried to constant weight at 80° C. has the melting point given under *Caffeina.* An aqueous solution of Citrated Caffeine (1 in 30) is acid to litmus paper. Dissolve about 0.02 Gm. of Citrated Caffeine in 1 cc. of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath. On inverting the dish over a vessel containing a few drops of ammonia T.S., the residue acquires a purple color, which disappears upon the addition of solutions of fixed alkalies (*murexide reaction*). About 2 cc. of a filtered aqueous solution of Citrated Caffeine (1 in 10) mixed with 50 cc. of lime water remains clear in the cold, but becomes turbid when heated to boiling. Add 1 cc. of mercuric sulphate T.S. to 5 cc. of an aqueous solution of Citrated Caffeine (1 in 100), heat the mixture to boiling, and add 1 cc. of potassium permanganate T.S.: a white precipitate is formed.

"Dried to constant weight at 80° C., Citrated Caffeine loses not more than 5 per cent. (*water*). Ash: not more than 0.1 per cent. Heat a mixture of 0.25 Gm. of Citrated Caffeine and 5 cc. of sulphuric acid in a porcelain dish on a water bath for fifteen minutes, protecting it from dust: it may become yellow but not brown or black (*tartrate*). An aqueous solution of Citrated Caffeine meets the requirements of the test for *heavy metals,* page 439. The addition of a few drops of barium chloride T.S. to 10 cc. of an aqueous solution of Citrated Caffeine (1 in 100), previously treated with a few drops of hydrochloric acid, produces no turbidity (*sulphate*).

"**Assay for Caffeine**—Dissolve about 0.5 Gm. of Citrated Caffeine, previously dried to constant weight at 80° C. and accurately weighed, in 10 cc. of hot distilled water, add 10 cc. of sodium hydroxide T.S., cool the solution, and shake it in a separator with three successive portions of 20 cc., 10 cc., and 5 cc., respectively, of chloroform, or more if necessary to complete the extraction. Evaporate the combined chloroform solutions on a water bath, dry the residue to constant weight at 80° C., and weigh.

"Preserve in well-closed containers." *U. S.*

The British Pharm. describes it as "a white powder with an acid reaction. Inodorous; taste acid and faintly bitter. Soluble in 4 parts of hot *water,* but dissociating on the further addition of *water* with separation of caffeine, which completely redissolves in 32 parts of *water.* Loses not more than 1 per cent. of its weight when dried at 100° C. When 1 gramme is dissolved in hot *water,* the solution made alkaline with *solution of sodium hydroxide* and shaken with three successive portions, each of 10 millilitres, of *chloroform,* the mixed chloroformic solutions, washed with a little *water,* leave on evaporation a residue weighing not less than 0.45 gramme, and responding to the test with *potassium chlorate* and *hydrochloric acid* described under 'Caffeina.' Caffeine Citrate yields the *reactions* characteristic of citrates." *Br.*

Uses.—Citrated caffeine is possessed of the physiological and therapeutic properties of caffeine, but is more liable to disagree with the digestive functions.

Dose, from three to eight grains (0.2 to 0.5 Gm.).

Off. Prep.—Caffeinæ Citras Effervescens, *Br.*

CAFFEINÆ CITRAS EFFERVESCENS. Br.

EFFERVESCENT CAFFEINE CITRATE

"It contains not less than 1.9 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4 = 194.12$]." *U. S.*

Caffeina Citrata Effervescens, *U. S. IX;* Effervescent Citrated Caffeine; Coffeïnum Citricum Effervescens; Braüsendes Koffeïncitrat, *G.;* Citrato Cafeico Effervescente, *Sp.*

"Sodium Bicarbonate, in powder, 510 grammes; Tartaric Acid, in powder, 270 grammes; Citric Acid, in powder, 180 grammes; Refined Sugar, in powder, 140 grammes; Caffeine Citrate, 40 grammes. Mix the Caffeine Citrate, Tartaric Acid, and Citric Acid; with this mixture thoroughly incorporate the mixed Sodium Bicarbonate and Refined Sugar; place in a dish or pan of suitable form heated to between 90° and 105° C. When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand grammes." *Br.*

This compound contains about two per cent. of caffeine. Samples of effervescent citrated caffeine have been found in the market very deficient in caffeine; the sweetening is sometimes effected by the use of saccharin instead of sugar. The powder affords an agreeable method of administering citrated caffeine.

Dose, one to two drachms (3.9–7.5 Gm.) in water, to be taken during effervescence.

CAFFEINÆ SODIO-BENZOAS. U. S.

CAFFEINE SODIO-BENZOATE Caff. Sod. Benz.

"A mixture of caffeine and sodium benzoate, which contains, when dried to constant weight at 80° C., not less than 47 per cent. nor more than 50 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4$ and not less than 50 and not more than 53 per cent. of sodium benzoate [$NaC_7H_5O_2$]." *U. S.*

Coffeinum Natrium Benzoicum; Benzoas Coffeini et Natrii.

Description and Physical Properties.—"A white, odorless powder, having a slightly bitter taste. One Gm. of Caffeine Sodio-Benzoate is soluble in 1.1 cc. of water, a portion of the caffeine usually separating on standing, and in 30 cc. of alcohol, at 25° C. It is partly soluble in chloroform.

"On heating, it is decomposed with the evolution of white vapors of caffeine, leaving a residue which effervesces with acids and colors a non-luminous flame intensely yellow. Ferric chloride T.S. produces a salmon-colored precipitate, and diluted hydrochloric acid produces a white precipitate in an aqueous solution of Caffeine Sodio-Benzoate. The residue obtained in the assay for caffeine when recrystallized from hot water, and dried to constant weight at 80° C., has the melting point of Caffeine, and responds to the other tests for identity under *Caffeina.*

"Its aqueous solution (1 in 20) may be neutral, slightly acid, or slightly alkaline to litmus paper, but is not reddened by phenolphthalein T.S. When dried to constant weight at 80° C., Caffeine Sodio-Benzoate loses not more than 5 per cent. of its weight (*water*). The solution of 0.1 Gm. of Caffeine Sodio-Benzoate in 2 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*). Dissolve about 2 Gm. of Caffeine Sodio-Benzoate in 40 cc. of distilled water in a separator, add 10 cc. of diluted sulphuric acid, extract the liberated benzoic acid with two successive 10 cc. portions of ether, and allow the ether solution to evaporate to dryness at room temperature: one-half Gm. of the benzoic acid so obtained complies with the test for *chlorinated compounds* under *Acidum Benzoicum.* Its aqueous solution (1 in 50) acidulated with hydrochloric acid and filtered, meets the requirements of the test for *heavy metals.*

"**Assay for Caffeine.**—Dissolve about 1 Gm. of Caffeine Sodio-Benzoate, previously dried to constant weight at 80° C. and accurately weighed, in 5 cc. of distilled water in a separator, add 5 cc. of sodium hydroxide T.S., and shake the mixture with four successive portions of 20 cc., 10 cc., 10 cc., and 5 cc., respectively, of chloroform. Pass the chloroform solutions through a filter which has been previously moistened with chloroform, and wash the stem of the funnel and filter with a few cc. of hot chloroform to remove any adhering caffeine. Evaporate the combined chloroform solutions on a water bath, and dry the residue, consisting of anhydrous caffeine, to constant weight at 80° C.

"**Assay for Sodium Benzoate.**—To the aqueous liquid from which the caffeine has been removed in the above assay for caffeine, add 10 cc. of diluted sulphuric acid, and extract the liberated benzoic acid with four successive portions of 20 cc., 10 cc., 10 cc., and 5 cc., respectively, of chloroform. Pass the chloroform solutions through a filter which has been previously moistened with chloroform, and wash the stem of the funnel and the filter with a few cc. of hot chloroform. Evaporate the combined chloroform solutions to about 5 cc. at a temperature not exceeding 40° C., add 25 cc. of diluted alcohol previously neutralized with tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal barium hydroxide to the restoration of the pink color. Each cc. of tenth-normal barium hydroxide corresponds to 0.01441 Gm. of sodium benzoate ($NaC_7H_5O_2$)." *U. S.*

Uses.—This compound has the physiological effects and therapeutic uses of caffeine. It has the advantage over the alkaloid of being freely soluble in water, and over the citrated caffeine of being less irritant to the stomach; whenever it is desired to exhibit caffeine in solution the preference should be given to caffeine and sodium benezoate. It is especially suitable for hypodermic administration for which purpose it may be dissolved in three parts of water and from ten to twenty minims (0.6–1.3 cc.) of this solution injected at a dose.

Dose, three to ten grains (0.2–0.6 Gm.).

Off. Prep.—Ampullæ Caffeinæ Sodio-benzoatis, *N. F.*

CALAMINA PRÆPARATA. N. F.

PREPARED CALAMINE. Calamin. Praep. [Lapis Calaminaris]

"Prepared Calamine is Zinc Oxide containing a small amount of ferric oxide. It contains, after ignition, not less than 98 per cent. ZnO." *N. F.*

Tutia Grisea; Nihilum Griseum; Galmei, Grauer Galmei, *G.;* Giallamina, *It.*

Calamine is the old name of the native *zinc carbonate,* although in mineralogy the name *calamine* is now applied to *zinc silicate,* while the name *smithsonite* is given to the carbonate. It is found in the United States, as well as in Belgium, Germany, and England. It occurs in compact or earthy masses, or concretions of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture, or it occurs crystallized in rhombic forms. Its color is very variable, being, in different specimens, grayish, grayish-yellow, reddish-yellow, and, when very impure, brown or brownish-yellow. Its sp. gr. varies from 3.4 to 4.4. Before the blow pipe it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids, and unless it has been previously calcined, emits bubbles of carbon dioxide.

Description and Physical Properties.—"Prepared Calamine is a pink powder passing through a No. 100 sieve. It is insoluble in water but dissolves in mineral acids, leaving a small amount of insoluble residue.

"A filtered solution of Prepared Calamine in diluted hydrochloric acid yields the reactions of zinc. Digest 1 Gm. of Prepared Calamine with 20 cc. of warm water, filter and add 2 drops of phenolphthalein T.S. If a red color is produced, not more than 0.2 cc. of tenth-normal sulphuric acid is required to discharge it (*alkaline substances*). 0.2 Gm. of Prepared Calamine dissolved in 5 cc. of diluted sulphuric acid meets the requirements of the Test for arsenic. Dissolve 1 Gm. of Prepared Calamine in 25 cc. of diluted hydrochloric acid, filter, and add to the filtrate ammonia water until the precipitate first formed is redissolved, then add 5 cc. more ammonia water. To 10 cc. of this solution add 2 cc. of ammonium oxalate T.S. Not more than a slight turbidity is produced (*calcium*). To another 10 cc. portion add 2 cc. of sodium phosphate T.S. Not more than a slight turbidity is produced (*calcium* or *magnesium*). To 1 Gm. of Prepared Calamine add 15 cc. of water, stir well, then add 3 cc. of glacial acetic acid, warm on the water bath until dissolved and filter. On adding 5 drops of potassium chromate T.S. to the filtrate no turbidity is produced (*lead*).

" **Assay.**—Ignite about 1.5 Gm. of Prepared Calamine, cool, weigh accurately and dissolve it by warming with 50 cc. of normal sulphuric acid. Filter, wash the residue and filter with hot distilled water until the washings are no longer acid to litmus paper, then titrate the combined cooled filtrate and washings with normal sodium hydroxide, using methyl orange as indicator. Each cc. of normal sulphuric acid corresponds to 0.04069 Gm. of ZnO." *N. F.*

Native zinc silicate, the calamine of the mineralogist, occasionally finds its way into pharmaceutical commerce through error. It may be distinguished by its complete insolubility in diluted hydrochloric acid. A spurious calamine composed of barium sulphate colored with iron oxide or aniline color is still to be found. " Calamina Præparata " made from precipitated carbonate of zinc and iron chloride should be used at the present time, as the natural product is no longer obtainable. (*Proc. New York Pharm. Assoc.*, 1915, p. 89.)

Uses.—Zinc carbonate has similar therapeutic virtues to the zinc oxide as a local application in the treatment of skin diseases. The chief use of native calamine depends, however, on its color; it is used to impart a flesh color to ointments, washes, and powders. As the pure zinc carbonate is white it ought not to be used when calamine is ordered.

Off. Prep.—Linimentum Calaminæ, *N. F.;* Lotio Calaminæ, *N. F.;* Lotio Calaminæ Composita, *N. F.;* Unguentum Calaminæ, *N. F.*

CALCII BROMIDUM. U. S.

CALCIUM BROMIDE Calc. Brom.

" Calcium Bromide is a hydrated salt, containing not less than 84 per cent. of CaBr$_2$." *U. S.*

Calcium Bromatum, Bromure de Calcium, Bromure de Chaux, *Fr.;* Brom Kalk, Calciumbromid, *G.*

Calcium bromide may be made by direct reaction of hydrobromic acid and calcium carbonate. Various other methods have been suggested; that of Macdonald (*A. J. P.*, 1873) is as follows: Dissolve 4 ounces of ammonium bromide in a pint of water. Put into a flask and bring to the boiling point. Keep boiling, and add milk of lime (made from *pure* calcined lime) in small quantities, until ammoniacal vapors cease to be evolved. The operator can easily tell when this point has been reached, by the sense of smell. Filter the solution, evaporate to a syrupy consistency, remove from the fire, and stir until cold. Tasilly prepares *calcium oxybromide* by adding three parts of calcium oxide in small portions to a solution of one hundred parts of calcium bromide in seventy-five parts of hot water; acicular crystals of calcium oxybromide CaBr$_2$3CaO,16H$_2$O, are deposited on cooling the filtered solution.

Description and Physical Properties.—" A white, granular salt, having no odor. It is very deliquescent. One Gm. of Calcium Bromide is soluble in 0.7 cc. of water and in 1.3 cc. of alcohol, at 25° C. One Gm. is soluble in 0.4 cc. of boiling water. It is insoluble in chloroform and in ether. An aqueous solution of the salt (1 in 20) responds to the reactions for calcium, and for bromides.

" An aqueous solution of Calcium Bromide (1 in 20) is neutral or slightly alkaline to litmus paper. Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20), and shake the mixture: the chloroform does not acquire a violet tint (*iodide*). Drop 1 cc. of diluted sulphuric acid upon about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*). Dissolve 0.1 Gm. of the salt in 5 cc. of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid, and filter. Wash the precipitate with distilled water, digest it for ten minutes with 5 cc. of ammonium carbonate T.S., and filter. Dilute the filtrate with enough distilled water to make 40 cc.: a 10 cc. portion of this dilution, acidulated with nitric acid and further diluted with enough water to make 50 cc., shows no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid, page 462. A 20 cc. portion of an aqueous solution of Calcium Bromide (1 in 250) does not at once assume a blue color with potassium ferrocyanide T.S. (*iron*). A 5 cc. portion of an aqueous solution of the salt (1 in 20), when acidulated with 1 drop of hydrochloric acid, shows no immediate turbidity with 1 cc. of barium chloride T.S. (*sulphate*). Dissolve 1 Gm. of Calcium Bromide and 1 Gm. of sodium acetate in 5 cc. of distilled water, and render the solution slightly acid by the addition of a sufficient quantity (from 3 to 5 drops) of diluted acetic acid. After boiling and thoroughly cooling the solution, it does not become cloudy within five minutes after the addition, with agitation, of five drops of potassium dichromate T.S. (*barium*). Precipitate the calcium completely from 10 cc. of an aqueous solution of Calcium Bromide (1 in 20) by adding ammonium oxalate T.S., and filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*). An aqueous solution of the salt meets the requirements of the test for *heavy metals*.

"**Assay.**—Proceed as directed under the assay for bromides, page 432, using about 0.5 Gm. of Calcium Bromide, accurately weighed in a stoppered weighing-bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.009996 Gm. of $CaBr_2$.

"Preserve in well-closed containers." *U. S.*

Uses.—If the calcium salts have, as there is reason to believe, anticonvulsant properties (see under *Calcium*) then the combination in calcium bromide is a rational one. Its action upon the lower animals has been partially investigated by Guttmann (*P. M. T.,* iv, p. 361) who finds that it is a sedative to the nerve centers and does not depress the heart. It may be used in the place of the other bromides in the treatment of *epilepsy, tetany,* or *hysteria,* but is not largely employed. It is sometimes of service in *asthma.*

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Elixir Bromidorum Quinque, *N. F.;* Syrupus Bromidorum, *N. F.*

CALCII CARBONAS PRÆCIPITATUS.
U. S., Br.

PRECIPITATED CALCIUM CARBONATE Calc. Carb. Præc. [Precipitated Chalk]

"It contains, when dried to constant weight at 200° C. not less than 98 per cent. of $CaCO_3$." *U. S.* "Precipitated Calcium Carbonate, $CaCO_3$, is obtained by the interaction of calcium chloride and sodium carbonate." *Br.*

Carbonas Calcicus Præcipitatus, Creta Præcipitata, Calcaria Carbonica Præcipitata; Precipitated Carbonate of Lime; Carbonate de Chaux Precipité, *Fr.;* Carbonate de Calcium, *Fr. Cod.;* Calcium carbonicum præcipitatum, *P. G.;* Calciumcarbonat; Präcipitirter kohlensaure Kalkerde, *G.;* Carbonato di calcio precipitato, *It.;* Carbonato de cal, *Sp.*

This salt may be made by the process of the U. S. P., 1870. It is as follows: "Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Sodium *seventy-two troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate of Sodium in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper."

Description and Physical Properties.—"A fine, white, microcrystalline powder, without odor or taste. It is stable in the air. Precipitated Calcium Carbonate is practically insoluble in water. The solubility is increased by the presence of ammonium salts and also by carbon dioxide. Alkali hydroxides diminish its solubility. It is insoluble in alcohol, and is dissolved with effervescence by diluted acetic, hydrochloric, or nitric acid, When heated to about 825° C., the salt gradually loses carbon dioxide, and a residue of calcium oxide remains. The addition of acetic acid to Precipitated Calcium Carbonate produces effervescence, and the resulting solution after boiling to expel carbon dioxide and neutralizing with ammonia T.S. responds to the reactions for calcium.

"Mix 2 Gm. of Precipitated Calcium Carbonate with 100 cc. of distilled water and add hydrochloric acid, drop by drop, with agitation until solution takes place. This solution does not impart a green or crimson color to a nonluminous flame, and a 10 cc. portion of the liquid does not respond to the test for *heavy metals,* page 439. Filter any insoluble residue remaining, wash with water until washings show no more chloride, and ignite: the weight of the residue does not exceed 0.004 Gm. Dissolve 0.5 Gm. of Precipitated Calcium Carbonate in 10 cc. of diluted hydrochloric acid, neutralize with ammonia T.S., completely precipitate the calcium by adding ammonium oxalate T.S., and then filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*).

"**Assay.**—Dry about 0.3 to 0.4 Gm. of Precipitated Calcium Carbonate to constant weight at 200° C., weigh accurately, dissolve it in 10 cc. of diluted hydrochloric acid and 10 cc. of distilled water, and boil the solution to expel all carbon dioxide. Transfer this solution to a 200 cc. volumetric flask, add 100 cc. of tenth-normal oxalic acid, render it alkaline with ammonia T.S., shake the mixture well, and allow it to stand for three hours at from 60° to 70° C., or over night at room temperature. Cool the liquid if necessary, fill the flask with distilled water to 200 cc., mix well, filter through a dry filter into a dry flask, reject the first 20 cc. of the filtrate, and proceed as follows: Acidulate 100 cc. of the filtrate (corresponding to one-half of the Precipitated Calcium Carbonate taken) with diluted sulphuric acid, then add 25 cc. more of the diluted sulphuric acid, warm the solution to about 65° C., and titrate with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid corresponds to 0.005004 Gm. of $CaCO_3$." *U. S.*

"A white microcrystalline powder insoluble in *water.* Yields the *reactions* characteristic of calcium and of carbonates. Yields no characteristic *reactions* for iron, aluminium, phosphates, or sulphates, and not more than the slightest *reactions* for magnesium or chlorides. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Bertholet has stated that the peculiar properties of precipitated calcium carbonate are largely dependent upon its micro-crystalline form. When precipitation is performed at 0°C. a light hydrated carbonate, almost entirely amorphous, is produced, having a density of only 1.7; if the precipitation is conducted at 30°C., the product consists of minute rhombohedra with a density of 2.7; if boiling solutions are employed, the precipitate consists of prismatic rhombohedra with a density of 2.9.

The denser form being easier to manipulate and wash, constitutes most of the precipitated calcium carbonate of commerce. It is much less readily attacked by acids and may pass through the intestinal tract unchanged.

Uses.—For ordinary purposes, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness.

It is not so desirable for tooth powders as chalk because, being in a crystalline state, it is more liable to abrade the tooth enamel.

Dose, from ten to forty grains (0.65–2.6 Gm.).

Off. Prep.—Trochiscus Bismuthi Compositus, *Br.*

CALCII CHLORIDUM. U. S., Br.

CALCIUM CHLORIDE Cal. Chlor.

"Calcium Chloride is a hydrated salt, containing not less than 75 per cent. of $CaCl_2$. Preserve it in well-stoppered bottles." *U. S.* "Calcium Chloride, $CaCl_2$, may be obtained by neutralizing hydrochloric acid with calcium carbonate, and carefully desiccating at a temperature not exceeding 200° C." *Br.*

Calcium Chloratum; Calcaria Muriatica; Chlorurum Calcicum; Chloridum Calcium; Muriate of Lime, Hydrochlorate of Lime; Chlorure de Calcium Cristallisé, *Fr.;* Chlorcalcium, Calciumchlorid, Salzsaures Kalk, *G.;* Cloruro di calcio, *It.;* Cloruro calcico, *Sp.*

The hydrated form of this salt has replaced the fused calcium chloride which was formerly official. Anhydrous calcium chloride may be readily formed by saturating hydrochloric acid with chalk or marble, evaporating to dryness, and heating to redness. The hydrochloric acid, be reacting with the calcium carbonate, forms calcium chloride, carbon dioxide, and water, the latter of which is dissipated at a red heat, $CaCO_3 + 2HCl = CaCl_2 + CO_2 + H_2O$. The crystallized or partly hydrated salt is prepared by allowing a concentrated solution to crystallize in a cool temperature. The Br. Ph. (1885), after neutralizing the acid with calcium carbonate, adds a little solution of chlorinated lime and slaked lime, filters, evaporates until the chloride becomes solid, and, instead of igniting the residue, dries it at about 204.4° C.

Description and Physical Properties.—"White, slightly translucent, hard, odorless fragments or granules. It is very deliquescent. One Gm. of Calcium Chloride is soluble in 1.2 cc. of water, and in about 10 cc. of alcohol, at 25° C. One Gm. is soluble in 0.7 cc. of boiling water and in about 2 cc. of boiling alcohol. An aqueous solution of the salt (1 in 10) responds to the reactions for calcium, and for chlorides.

"An aqueous solution of Calcium Chloride (1 in 20) is neutral or slightly alkaline to litmus paper. Add ammonia water to an aqueous solution of the salt (1 in 20) until alkaline: no turbidity or precipitation occurs either before or after boiling (*iron, aluminum, or phosphates*). Precipitate the calcium completely from 10 cc. of an aqueous solution of the salt (1 in 20) by adding ammonium oxalate T.S., and filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of residue (*magnesium or alkalies*). An aqueous solution of the salt does not respond to the test for *heavy metals.*

"**Assay.**—Proceed as directed under the assay for chlorides, page 432, using about 0.3 Gm. of Calcium Chloride, accurately weighed in a stoppered weighing-bottle. Each cc. of tenth-normal silver nitrate corresponds to 0.00555 Gm. of $CaCl_2$.

"Preserve in well-stoppered bottles." *U. S.*

"Dry, white, very deliquescent masses. Taste warm, slightly bitter. Soluble in 1.5 parts of *water,* and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of calcium and of chlorides. Yields no characteristic *reactions* for iron, aluminium, or carbonates, and not more than the slightest *reactions* for magnesium. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Evolves no chlorine or hypochlorous acid on the addition of *hydrochloric acid* (absence of hypochlorite). Loses not more than 5 per cent. of its weight when dried at 200° C." *Br.*

On account of its avidity for water, the fused salt is used for drying gases and in desiccators. The crystallized salt is also very deliquescent, and has the form of colorless, transparent, striated, six-sided prisms. The crystals, on exposure to heat, first dissolve in their water of crystallization, and, after this has evaporated, undergo igneous fusion. With ice or snow they form a powerful frigorific mixture. Calcium chloride exists in the water of the ocean and of many springs. It is usually associated with common salt and magnesium chloride, from which it is separated with difficulty. When crystallized it normally contains six molecules of water, but other crystalline hydrates have also been obtained.

Uses.—For consideration of the rôle of this element in physiology and the general therapeutic use see under *Calcium.* As an available source of calcium the chloride has been extensively employed in the treatment of internal *hemorrhages* such as *hemoptysis, menorrhagia* and *hemophilia.*

Within recent years calcium chloride has attracted some attention as a diuretic in cases of general *anasarca.* Keith, Barrier and Whelan (*J. A. M. A.*, 1924, lxxxiii, p. 666) attribute its beneficial effect in these cases to the fact that it causes an increased elimination of sodium chloride.

In some way not at present evident the lime salts diminish the susceptibility of guinea-pigs to the condition known as *anaphylaxis* which follows the injection of foreign protein. It has, therefore, been used clinically and with apparent good results not only to prevent the *serum disease* after the injection of antitoxins, but in the treatment of *hay fever, asthma, urticaria, laryngismus stridulus, hemoglobinuria,* etc. Following the example of a Swedish physician named Saxtorph a number of clinicians have used calcium chloride by intravenous injection for the relief of *tubercular diarrhea.* A single injection of 5 cc. of a 5 per cent. solution (equivalent to a dose of 0.25 Gm.—four grains) will often cause permanent relief (Fishberg, *J. A. M. A.,* 1919, lxxii, 1881). The treatment is apparently not entirely free from danger as in one case reported by Fishberg there was serious collapse. Calcium chloride should never be administered hypodermically because of its strong local destructive effect on the subcutaneous tissues (see Seelig, *J. A. M. A.,* 1925, lxxiv).

The *dose* ordinarily recommended is five to fifteen grains (0.32–1.0 Gm.), but it is very doubtful whether such a quantity by the mouth can exercise any effect on the system, and as the salt is relatively innocuous larger doses would seem more rational; a more reasonable dose would be twenty to thirty grains (1.3–2.0 Gm.).

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.*

CALCII GLYCEROPHOSPHAS. U. S.

CALCIUM GLYCEROPHOSPHATE Calc. Glycerophos. [Calcium Glycerinophosphate]

"The normal calcium salt of glycerophosphoric acid [$C_3H_5(OH)_2PO_4H_2 = 172.11$], containing, when dried to constant weight at 130° C., not less than 98 per cent. of $C_3H_5(OH)_2PO_4Ca$." *U. S.*

Glycerophosphate of Lime, Calcium Phosphoglycerate; Glycerophosphate de chaux, *Fr.;* Glycerophosphate de Calcium, *Fr. Cod.*

There are several theoretically possible *glycerides of phosphoric acid,* but the only one of any practical significance is the *monoglyceride of ortho-phosphoric acid* of the composition $CH_2OH.CHOH.CH_2O.PO(OH)_2$. This compound, called for brevity's sake *glycerophosphoric acid,* was discovered by Pelouze in 1846, while studyng glycerol-sulphuric acid, an analogous compound. Other authors soon discovered the presence of salts of this new acid in yolk of egg, brain tissue and other organic sources. Being called to the attention of the medical profession, a demand soon arose for the glycerophosphates of the various elements, which in some cases, as that of sodium, was supplied by the furnishing of spurious articles, mixtures of inorganic salts and glycerin being substituted for them.

Glycerophosphoric acid is a dibasic acid and therefore is capable of combining with bases to form normal or acid salts, which occur in varying conditions of hydration. The official calcium glycerophosphate is the normal salt and has the formula $Ca.\ C_3H_5(OH)_2.PO_4$. The acid salt has the formula $Ca.[C_3H_5(OH)_2HPO_4]_2$. This latter compound does not exist as a solid salt, but is usually found in the form of a 50 per cent. solution, higher concentrations being unstable. The advantage of the acid salts is their more ready solubility, which, however, is counter-balanced by the acidity, which prevents their use subcutaneously. The solubility of the normal salts can be greatly increased by the addition of a small proportion of lactic acid, citric acid or of sodium citrate. The solubility is diminished by the presence of alcohol, glycerin or solutions of other glycerophosphates.

The normal salt is made by treating glycerophosphoric acid with calcium hydroxide and purifying the product by treatment with alcohol.

Description and Physical Properties.—"A fine, white, odorless powder. It is somewhat hygroscopic. One Gm. of Calcium Glycerophosphate is soluble in about 50 cc. of water at 25° C. It is more soluble in water at a lower temperature; citric acid increases its solubility in water. It is insoluble in alcohol.

"A saturated aqueous solution of Calcium Glycerophosphate is alkaline to litmus paper and to phenolphthalein T.S. A cold, saturated aqueous solution of the salt upon boiling yields white, iridescent scales of anhydrous calcium glycerophosphate. When heated above 170° C., the salt is decomposed, evolving inflammable vapors, and at a red heat is converted into calcium pyrophosphate. A saturated aqueous solution of the salt responds to the reactions for calcium, and for glycerophosphates. With lead acetate T.S. a saturated aqueous solution of the salt yields a white curdy precipitate, which is soluble in nitric acid.

"Dissolve 1 Gm. of Calcium Glycerophosphate in 10 cc. of diluted nitric acid, and add an equal volume of cold ammonium molybdate T.S.: no precipitate is formed within one hour (*phosphates*). An aqueous solution of the salt meets the requirements of the test for *heavy metals.* One Gm. of Calcium Glycerophosphate shows no more *chloride* than 1 cc. of fiftieth-normal hydrochloric acid, page 462. Two-tenths of 1 Gm. of Calcium Glycerophosphate shows no more *sulphate* than 1 cc. of fiftieth-normal sulphuric acid, page 462. Shake 1 Gm. of finely powdered Calcium Glycerophosphate with 25 cc. of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water bath, and dry the residue for an hour at a temperature not exceeding 70° C.: the resulting residue weighs not more than 0.01 Gm. (*alcohol-soluble substances*). The loss on drying a portion of the finely powdered salt to constant weight at 130° C., does not exceed 10 per cent. (*water*). Dry about 3 Gm. of Calcium Glycerophosphate to constant weight at about 130° C., weigh accurately, dissolve it in 250 cc. of distilled water, and then titrate with half-normal hydrochloric acid, using methyl orange T.S. as indicator, to a slight yet distinct pink. Each Gm. of dry Calcium Glycerophosphate requires not less than 9 cc. of half-normal hydrochloric acid (*minimum limit for glycerophosphate*).

"**Assay.**—Dry about 0.4 Gm. of Calcium Glycerophosphate to constant weight at 130° C., weigh accurately, dissolve in 20 cc. of a 5 per cent. solution of acetic acid, and add 30 cc. of distilled water. Heat the mixture to boiling, and add an excess of ammonium oxalate T.S. Collect the resulting precipitate, wash, dry, and ignite to constant weight. This residue of calcium oxide corresponds to not less than 26.1 per cent. of the weight of dried Calcium Glycerophosphate taken. Dry a portion of Calcium Glycerophosphate to constant weight at 130° C., and ignite it to constant weight. The weight of calcium pyrophosphate corresponds to not less than 59.2 per cent. of the weight of Calcium Glycerophosphate taken.

"Preserve in well-closed containers." *U. S.*

Uses.—The phosphorus of the central nervous system exists in the form of an organic combination of glycerophosphoric acid. On the theory that glycerophosphoric acid could be directly absorbed and utilized as a nutriment for the central nervous system, various salts of the glycerophosphates have been introduced into medicine. There is, however, no convincing evidence that the central nervous system can metabolize the glycerophosphates any better than ordinary phosphates; moreover in conditions of nerve weakness in which this group of remedies is supposed to be indicated, the fault is due not to the absence of phosphorus in the food but to errors in the metabolic processes of the nervous system. While theory does not support the use of glycerophosphates as nerve tonics, there is considerable clinical evidence as to their value in conditions of *debility,* as *neurasthenia.* The calcium glycerophosphate represents any virtue that may pertain to the glycerophosphoric acid and adds to it the value of the calcium. It has been used also in various *bone diseases,* such as *rickets* and also in *tubercular* complaints. Blackader (*J. A. M. A.*, 1912, lix) believes that any therapeutic value that calcium glycerophosphate may possess is due to its content of lime. Theoretically it should, for many purposes, be superior to most other calcium salts because it represents both calcium and phosphoric acid in a soluble combination (see *Calcium Phosphate*).

Dose, three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Elixir Calcii et Sodii Glycerophosphatum, *N. F.;* Elixir Glycerophosphatum Compositum, *N. F.;* Elixir Terpini Hydratis et Creosoti Compositum, *N. F.*

CALCII HYDRAS. Br.

CALCIUM HYDROXIDE

"Calcium Hydroxide, $Ca(OH)_2$, is the product, recently prepared, of the interaction of water and Lime." *Br.*

Calcis Hydras; Slaked Lime; Hydrate of Lime; Chaux Eteinte, *Fr. Cod.;* Idrato di calcio, *It.*

The British Parmacopœia no longer gives a detailed process for slaked lime. The process of the Br. Pharm. (1885) is as follows: "Take of Lime *two pounds* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Place the lime in a metal pot, pour the water upon it, and when vapor ceases to be disengaged cover the pot with its lid and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron-wire sieve, and by the gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stoppered bottle, and keep it excluded as much as possible from the air. Slaked lime should be recently prepared." *Br.,* 1885. Calcium hydroxide "is a soft, white powder. Yields the *reactions* characteristic of calcium. Strongly heated it loses nearly one-fourth of its weight of water. Yields not more than the slightest characteristic *reactions* for iron, carbonates, chlorides, sulphates, or silica. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

For an account of the physical and medicinal properties of slaked lime, see *Calx.*

Off. Prep.—Liquor Calcis, *Br.;* Liquor Calcii Saccharatus, *Br.*

CALCII HYPOPHOSPHIS. N. F., Br.

CALCIUM HYPOPHOSPHITE Calc. Hypophos.

"Calcium Hypophosphite contains, when dried to constant weight over sulphuric acid, not less than 98 per cent. of $Ca(PH_2O_2)_2$ (170.18)." *N. F.*

"Calcium Hypophosphite may be obtained by the interaction of phosphorus, calcium hydroxide, and water. It contains not less than 98 per cent. of pure calcium hypophosphite, $Ca(PH_2O_2)_2$." *Br.*

Calcis Hypophosphis; Calcium Hypophosphorosum; Hypophosphite of Lime; Calcaria Hypophosphorosa, Hypophosphis Calcicus; Hypophosphite de Chaux, *Fr. Cod.;* Unterphosphorigsaure Kalkerde, Calcium hypophosphit, *G.;* Hipofosfito calcico, *Sp.*

Calcium hypophosphite may be prepared by the following method, originally devised by Procter: Slake four pounds (avoirdupois) of lime with a gallon of water, add it, in a deep boiler, to four gallons of boiling water, and mix thoroughly. To the mixture add a pound (av.) of phosphorus, and continue the boiling, adding hot water from time to time to keep up the measure, until the combination is complete, and hydrogen phosphide is no longer evolved. It is necessary to provide for the escape of the gas, which takes fire spontaneously in contact with air. There are formed in the liquid calcium phosphate and hypophosphite, the phosphorus oxidizing at the expense of the water, the hydrogen of which has escaped in combination with another portion of phosphorus, which is therefore lost. The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated until a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat and stirring. The salt should be introduced into bottles. The former Br. Pharm. practically adopted this process, but any uncombined lime remaining in the solution was separated by passing carbonic acid gas through it.

Description and Physical Properties.—"Calcium Hypophosphite occurs as colorless, transparent, monoclinic prisms, as small lustrous scales, or as a white, crystalline powder; odorless, having a nauseous and bitter taste. One Gm. of Calcium Hypophosphite is slowly soluble in 6.5 cc. of water at 25° C.; insoluble in alcohol.

"When heated the salt decrepitates and begins to decompose, giving off water and evolving spontaneously inflammable hydrogen phosphide, and on complete ignition leaving a residue of calcium pyrophosphate. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Calcium Hypophosphite the precipitate becomes gray from reduction to metallic mercury. An aqueous solution of Calcium Hypophosphite (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.

"Dissolve 1 Gm. of the salt in 20 cc. of distilled water; it requires not more than 1 cc. of tenth-normal potassium hydroxide to produce a pink color, phenolphthalein T.S. being used as indicator. When 1 Gm. of the salt is dissolved in 20 cc. of distilled water, not more than 0.005 Gm. of residue remains (*phosphate*). Mix 5 cc. of an aqueous solution of the salt (1 in 10) in a test tube with 0.5 cc. of diluted hydrochloric acid and heat on a water bath; no offensive odor develops within thirty minutes. An aqueous solution of the salt does not respond to the Test for heavy metals. Pour 5 cc. of an aqueous solution of the salt (1 in 25) into a beaker containing 3 cc. of nitric acid, diluted with about 10 cc. of distilled water, and evaporate it to dryness on a water bath. The residue meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 0.75 Gm. of Calcium Hypophosphite, previously dried to constant weight over sulphuric acid and accurately weighed, in 10 cc. of distilled water, add 10 cc. of nitric acid and evaporate to dryness on a water bath. Add 5 cc. of nitric acid to the residue, again evaporate to dryness on a water bath and dissolve the residue in sufficient distilled water to measure 100 cc. Transfer 10 cc. of this solution to a 100 cc. graduated flask, add sodium hydroxide T.S. (free from chloride) until a slight, permanent precipitate is produced; then add 50 cc. of tenth-normal silver nitrate and agitate well. Then gradually add zinc oxide (free from chloride) in small portions until the liquid is neutral to litmus. Then add distilled water to make 100 cc., agitate the mixture thoroughly, filter through a dry filter, rejecting the first 20 cc. of filtrate, collect 50 cc. of the subsequent filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate to the production of a red color. Each cc. of tenth-normal silver nitrate corresponds to 0.002836 Gm. of $Ca(PH_2O_2)_2$. Each Gm. of Calcium Hypophosphite, dried to constant weight, corresponds to not less than 345.5 cc., of tenth-normal silver nitrate.

"Preserve it in well-closed containers. Caution should be observed in dispensing Calcium Hypophosphite as an explosion is liable to occur if it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *N. F.*

"A white crystalline salt, with a pearly lustre; taste bitter, nauseous. Soluble in 8 parts of *water;* insoluble in *alcohol* (90 per cent.). When strongly heated evolves spontaneously-inflammable hydrogen phosphide and hydrogen, and leaves a reddish residue. Yields the *reactions* characteristic of calcium. Its aqueous solution yields with *T. Sol. of mercuric chloride* a white precipitate turning grey. Yields no characteristic *reactions* for copper or iron, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Contains not less than 98 per cent. of pure calcium hypophosphite, $Ca\ (PH_2O_2)_2$, as determined by the following process: Dissolve 2.5 grammes in 40 millilitres of *water;* add 5 millilitres of *solution of lead acetate* and sufficient *water* to produce 50 millilitres; shake the mixture well and allow it to stand for one hour for the precipitate to subside. To 10 millilitres of the clear liquid add 50 millilitres of *N/1 solution of potassium bichromate* and 10 millilitres of *sulphuric acid;* heat on a water-bath for one hour, cool, and add sufficient *water* to produce 250 millilitres. To 25 millilitres of this solution add 2 grammes of *potassium iodide* and titrate the liberated iodine with *N/10 solution of sodium thiosulphate, mucilage of starch* being used as indicator; not more than 27 millilitres are required." *Br.*

The solubility of calcium hypophosphite is increased by the addition of hypophosphorous acid. For a method of purifying alkaline hypophosphites, see *J. P. A.,* 1879, 57; *N. R.,* 1879, 142.

As the soluble salts of mercury, copper, and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With calcium hypophosphite all the soluble sulphates and carbonates produce precipitates. As the hypophosphites are insoluble in cod liver oil, they should be dissolved in syrup or water before being added to the emulsion of the oil. (See *Syrupus Hypophosphitum* and *Emulsum Olei Morrhuæ cum Hypophosphitibus.*) W. A. H. Naylor considers the presence of sulphites in commercial hypophosphites to be the source of the disagreeable odor of hydrogen sulphide sometimes found in the compound syrup of hypophosphites. (*P. J.,* 1895, 144.)

Uses.—Calcium hypophosphite was at one time largely used in *chronic phthisis,* in various *scrofulous affections,* in *neurasthenia,* and other conditions of impaired nutrition of the nerve centers. Although frequently prescribed for its hypophosphite ion, as pointed out elsewhere, the latter probably is therapeutically inert and it is very doubtful whether it has any therapeutic virtues other than that of the soluble calcium salts generally.

Dose, ten to thirty grains (0.65–2.0 Gm.), three times a day.

Off. Prep.—Syrupus Hypophosphitum, *N. F.;* Emulsum Olei Morrhuæ cum Hypophosphitibus, *N. F.;* Liquor Hypophosphitum Compositus, *N. F.;* Syrups Calcii et Sodii Hypophosphitum, *N. F.;* Syrupus Calcii Hypophosphitibus, *N. F.;* Syrupus Hypophosphitum Compositus, *N. F.*

CALCII IODOBEHENAS. U. S.

CALCIUM IODOBEHENATE Calc. Iodobehen.
[Calioben, Calcium Monoiodobehenate]

"Calcium Iodobehenate consists principally of calcium monoiodobehenate $[(C_{21}H_{42}ICOO)_2Ca]$ and contains, when dried to constant weight at 100° C., not less than 23.5 per cent of iodine [I]." *U. S.*

Erucic acid, one of the higher fatty acids found in the fixed oils of various seeds, notably of the mustards and grapes, is closely related to behenic acid which occurs in smaller quantities in mustard seeds, but is the chief fatty acid of oil of ben (see Part II). When erucic acid is treated with hydriodic acid it yields mono-iodobehenic acid. This latter combines with calcium to form a white odorless salt, analogous to the soaps, containing about 26 per cent. of iodine, which was introduced as a medicine under the trade name of *sajodin.*

Description and Physical Properties.—"A white or yellowish powder, unctuous to the touch. It is odorless or has a slightly fat-like odor. Calcium Iodobehenate is insoluble in water, very slightly soluble in alcohol and in ether, but freely soluble in warm chloroform.

"When strongly heated, Calcium Iodobehenate is decomposed, with the evolution of violet vapors of iodine and of white vapors having an odor of burning fat. Heat about 0.2 Gm. of Calcium Iodobehenate with 2 cc. of sulphuric acid on a water bath during five to ten minutes, cool, add 2 cc. of chloroform, and shake gently: the chloroform, upon separation, is colored violet.

"Add 10 cc. of diluted hydrochloric acid to 1 Gm. of Calcium Iodobehenate: no effervescence occurs (*carbonate*). Add 40 cc. of distilled water, and boil gently: a layer of fatty acid which is soluble in ether and chloroform separates on the surface. Make the aqueous layer slightly alkaline with ammonia T.S., and add an excess of ammonium oxalate T.S. (about 5 cc.): a white precipitate of calcium oxalate is produced. Allow to stand for four hours, filter, evaporate the filtrate to dryness, and ignite: the residue does not exceed 0.003 Gm. (*magnesium or alkali salts*). Dried to constant weight at 100° C., Calcium Iodobehenate loses not more than 2 per cent. (*water*). One Gm. of Calcium Iodobehenate dissolves in 10 cc. of warm chloroform with not more than an opalescence. Triturate 1 Gm. of Calcium Iodobehenate with 10 cc. of distilled water: the mixture is neutral to litmus paper. Add 15 cc. more of distilled water, mix well during five minutes, and filter. Evaporate 10 cc. of the filtrate to dryness on a water bath, and dry to constant weight at 120° C.: the weight of the residue does not exceed 0.001 Gm. (*soluble salts*). Other 5 cc. portions of the filtrate, tested for halogens and sulphate as described under turbidimetric tests, show no greater turbidity than 0.1 cc. of fiftieth-normal hydrochloric acid or sulphuric acid, page 462. Add 40 cc. of tenth-normal hydrochloric acid to about 1 Gm. of Calcium Iodobehenate, previously dried to constant weight at 100° C., and accurately weighed, and boil gently in a flask until thoroughly decomposed. Cool, and titrate the excess of acid with tenth-normal sodium hydroxide, using methyl orange T.S. as indicator: not less than 20 cc. and not more than 20.6 cc. of the tenth-normal acid is consumed.

"**Assay.**—Mix about 0.5 Gm. of Calcium Iodobehenate, previously dried to constant weight at 100° C. and accurately weighed, with about 3 Gm. of anhydrous potassium carbonate. Place the mixture in a platinum crucible, cover with about 1 Gm. more of anhydrous potassium carbonate, and heat moderately, gradually increasing the heat, but not exceeding a dull redness, until completely carbonized. Extract the residue with boiling distilled water, and wash it on the filter with boiling distilled water until the washings produce no opalescence with silver nitrate T.S. Heat the combined filtrate and washings, which measure about 150 cc., on a water bath, and add an aqueous solution of potassium permanganate (1 in 20) in small portions, until the hot liquid remains permanently pink. Add just enough alcohol to remove the pink tint, cool to room temperature, dilute to 200 cc., mix well, and filter through a dry filter, rejecting the first 50 cc. of filtrate. To 100 cc. of the subsequent clear filtrate add about 1 Gm. of potassium iodide (free from iodate) and an excess of diluted sulphuric acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, adding starch T.S. near the end of the titration. Each cc. of tenth-normal sodium thiosulphate used corresponds to 0.002115 Gm. of iodine.

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—The action of calioben probably depends entirely on the liberation of iodine and therefore resembles in its general action the alkaline iodides. Its solubility relations, however, give it certain advantages over the older iodides, for some purposes, although for others it is inferior. Being practically insoluble in the gastric juice, it is not irritating to the stomach. Although it has been abundantly demonstrated that it is absorbed from the intestinal canal, its absorption is much slower and apparently somewhat less complete than with the inorganic iodides; Broking (*Z. E. P. T.,* 1905, ii, 416) found that after the oral administration, iodine did not appear in the saliva nor urine for at least one hour and that 84 hours were required for the complete elimination of a single dose. He further showed that from 7 to 10 per cent. of the calioben could be recovered unchanged from the feces. It is not known in exactly what form the iodized fatty acid is absorbed; but evidently the iodine is not liberated from the compound in the intestinal tract. This is shown not only by the fact of its relatively slow excretion, but also by the distribution of the iodine in the body tissues. McLean (*A. In. M.,* November, 1912 and January, 1915) has shown that after the administration of potassium iodide, from 30 to 32 per cent. of the iodine is retained in the lipoid portion of the internal organs and from 67 to 70 per cent. as a water soluble compound, while with an iodized fatty acid, such as calioben, from 50 to 75 per cent. of the iodine is in the tissues in a lipoid soluble form. Because of its slower absorption, iodism is much less likely to occur after calioben than after the iodides, and Boulaire (*C. R. S. B.,* 1906, lvi. 303) has shown that the iodized fats are the least toxic of the iodine compounds. It would appear from the above that calioben is absorbed either from the alimentary tract or from the subcutaneous tissues in a materially unchanged form—perhaps in fatty solution—and deposited in the adipose and lipoid tissues where it is slowly decomposed, liberating ionic iodine. Whether or not the organic molecule—in which form the calioben circulates in the blood—has any effect upon the body functions is, as yet, not determined, but at present the compound is used purely for its iodine action. Where a long-continued mild effect of iodine is desired, calioben is superior to the inorganic iodides, not merely because of the comparative freedom from gastric disturbances and the lesser liability of iodism, but also because the amount of iodine in the blood is much more constant. On the other hand, where a rapid profound effect is required the inorganic salts are superior. Calioben has been especially recommended in the treatment of *chronic bronchitis, asthma, arterio-sclerosis, chronic arthritis* and other chronic conditions where the iodides are indicated.

Dose, from fifteen to forty-five grains (1–3 Gm.).

CALCII LACTAS. U. S., Br.

CALCIUM LACTATE Calc. Lact.

"Calcium Lactate contains not less than 70 per cent. and not more than 75 per cent. of $Ca(C_3H_5O_3)_2$, corresponding to not less than 98 per cent. of the hydrated salt [$Ca(C_3H_5O_3)_2.5H_2O$]." *U. S.* "Calcium Lactate may be obtained by neutralising dilute lactic acid with calcium carbonate and evaporating the resulting solution. It contains not less than 93 per cent. of pure calcium lactate, $Ca(C_3H_5O_3)_2,5H_2O$." *Br.*

Calcium Lacticum; Lactas Calcicus; Milchsaures Kalk, *G.*

This salt was introduced into the U. S. P. IX and the Br. Pharm., 1914. The experiments of C. A. Hill and T. T. Cocking (*Y. B. P.,* 1912, 481) demonstrate that calcium lactate is liable to vary in composition according to the method of preparation, varying particularly in the amount of water of crystallization. It may be neutral or contain either lactic acid, calcium hydroxide, or calcium carbonate. *Pure* calcium lactate is readily prepared by precipitation of ing the precipitate with acetone and then with its cold saturated solution with acetone, wash- ether.

Description and Physical Properties.—"White, granular masses or powder. It is odorless or has a slight odor. It is somewhat efflorescent and at 120° C. becomes anhydrous. One Gm. of Calcium Lactate is soluble in 20 cc. of water at 25° C. It is practically insoluble in alcohol. An aqueous solution of the salt (1 in 20) responds to the reactions for calcium, and for lactates.

"When dried to constant weight at 120° C., Calcium Lactate loses not less than 25 per cent. and not more than 30 per cent. of its weight. A solution of 1 Gm. of Calcium Lactate in 20 cc. of distilled water requires not more than 0.5 cc. of tenth-normal sodium hydroxide for neutralization, using phenolphthalein T.S. as indicator. An aqueous solution of the salt meets the requirements of the test for *heavy metals.* Add ammonium oxalate T.S. to 20 cc. of a hot aqueous solution of Calcium Lactate (1 in 20) until no further precipitate is produced, filter the mixture after three hours, and wash the precipitate with 50 cc. of distilled water: the combined filtrate and washings leave not more than 0.01 Gm. of residue on evaporation and subsequent ignition (*magnesium or alkalies*). Stir about 0.5 Gm. of the salt with 1 cc. of sulphuric acid: the mixture does not emit an odor of volatile fatty acids even on warming.

"**Assay.**—Dry about 2 Gm. of Calcium Lactate to constant weight at 120° C., weigh accurately in a crucible, incinerate, wash the incinerated residue into a flask with about 50 cc. of distilled water, add exactly 50 cc. of half-normal hydrochloric acid, and titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal hydrochloric acid corresponds to 0.05455 Gm. of $Ca(C_3H_5O_3)_2$.

"Preserve in well-closed containers." *U. S.*

"A white powder; almost tasteless. Slowly soluble in 18.5 parts of *water,* forming a clear, colorless solution. Yields the *reactions* characteristic of calcium. The aqueous solution, acidified with *sulphuric acid* and warmed with *potassium permanganate,* develops the odor of aldehyde. A solution of 5 grammes in hot *water* does not become pink on the addition of a few drops of *solution of phenolphthalein,* and requires not more than 0.5 millilitre of *N/1 solution of sodium hydroxide* to produce a pink coloration (limit of acidity). One gramme, treated with *sulphuric* acid and incinerated in a crucible, cooled, again treated with *sulphuric acid* and incinerated, leaves a white residue weighing not less than 0.410 and not more than 0.450 gramme. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—Calcium lactate affords an excellent means of obtaining the therapeutic effects of lime. It is asserted that it not only is less likely to disturb the stomach than the chloride, but is more readily absorbed. It is used in the treatment of *hemorrhage, rickets,* and other diseases in which the lime salts are indicated. (See *Calcium*). Luckhardt and Goldberg (*J. A. M. A.,* 1923 lxxx, 79) obtained results in *tetany* from the lactate which they could not from other calcium salts.

The *dose* is fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Syrupus Calcii Lactophosphatis, *Br.*

CALCII LACTOPHOSPHAS. N. F.

CALCIUM LACTOPHOSPHATE Calc. Lactophos.

"A mixture in variable proportions of calcium lactate, calcium acid lactate, and calcium acid phosphate, corresponding to not less than 1.5 per cent. and not more than 2 per cent. of phosphate oxide (P_2O_5)."

Calcium Lactophosphoricum; Lactophosphate de Calcium, *Fr. Cod.*

Description and Physical Properties.—"Calcium Lactophosphate occurs in white granules or as a white powder, without odor. It is soluble in water, almost insoluble in alcohol. Its aqueous solution (1 in 20) is acid to litmus.

"The addition of ammonium oxalate T.S. to an aqueous solution of Calcium Lactophosphate produces a white precipitate insoluble in acetic acid but soluble in hydrochloric acid. Add 10 cc. of diluted sulphuric acid and 5 cc. of potassium permanganate T.S. to 5 cc. of an aqueous solution of Calcium Lactophosphate (1 in 20) and gently warm the mixture; the odor of acetaldehyde is evolved. Add silver nitrate T.S. or ammonium molybdate T.S. to separate portions of an aqueous solution of Calcium Lactophosphate (1 in 20); a yellow precipitate is produced.

"Mix 0.5 Gm. of Calcium Lactophosphate with 5 cc. of sulphuric acid; not more than a slight coloration results within one minute (*readily carbonizable impurities*). Ten cc. of an aqueous solution of Calcium Lactophosphate (1 in 100) mixed with 1 cc. of diluted hydrochloric acid, does not at once become turbid on the addition of a few drops of barium chloride T.S. (*sulphate*). Ten cc., of an aqueous solution of Calcium Lactophosphate (1 in 100) when mixed with a few drops of nitric acid, yields not more than an opalescence on the addition of a few drops of silver nitrate T.S. (*chloride*). An aqueous solution of Calcium Lactophosphate does not respond to the Test for heavy metals. Mix 0.2 Gm. of Calcium Lactophosphate with 1 Gm. of potassium nitrate, ignite the mixture cautiously, in small portions at a time, until the carbonaceous matter is all or nearly all burned off, then add to the residue 20 cc. of diluted sulphuric acid and evaporate the mixture until fumes of sulphuric anhydride are evolved. The residue meets the requirements of the Test for arsenic. Dissolve 1 Gm. of Calcium Lactophosphate and 2 Gm. of ammonium chloride in 75 cc. of distilled water, heat the solution to boiling and add an excess of ammonium oxalate T.S. (about 20 cc.). Allow the precipitate to subside completely, then filter and supersaturate the filtrate with ammonia water; not more than a slight turbidity is produced (*magnesium*).

"**Assay.**—Dissolve about 1 Gm. of Calcium Lactophosphate accurately weighed, in a mixture of 15 cc. of distilled water and 10 cc. of nitric acid contained in a 200 cc. beaker, and then add ammonia T.S. to a point just short of neutralization. Dilute the solution to 100 cc., heat to 60° C., add 25 cc. of ammonium molybdate T.S. and agitate well. Allow the mixture to remain at 60° for fifteen minutes, then filter through paper and wash with distilled water until the washings are neutral. Transfer the precipitate and filter back to the beaker, dissolve the precipitate in 30 cc. of half-normal sodium hydroxide, and titrate the excess of alkali with half-normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of half-normal alkali corresponds to 0.001544 Gm. of P_2O_5." *N. F.*

Uses.—Calcium lactophosphate probably represents the therapeutic virtues of calcium phosphate, its chief advantage residing in its solubility which makes it easier to administer, especially to children. It is largely employed in the treatment of *rickets* and other bone diseases, especially in the form of the syrup.

Dose, five to ten grains (0.3–0.6 Gm.).

Off. Prep.—Elixir Calcii Lactophosphatis, *N. F.;* Syrupus Calcii Lactophosphatis *N. F.;* Syrupus Calcii Lactophosphatis et Ferri, *N. F.*

CALCII PHOSPHAS PRÆCIPITATUS. N. F. (Br.)

PRECIPITATED CALCIUM PHOSPHATE Calc. Phos. Præ.

"Calcium Phosphate ($Ca_3(PO_4)_2 = 310.29$) losing, when dried at 200° C. not more than 4 per cent. of moisture." *N. F.*

"Calcium Phosphate may be obtained by the interaction of calcium chloride with sodium phosphate and excess of ammonia at a boiling temperature." *Br.*

Calcii Phosphas, *Br.;* Calcium Phosphate; Tricalcium Phosphate, Tribasic Calcium Phosphate, Calcaria Phosphorica; Phosphas Calcicus Præcipitatus; Phosphas Tricalcicus; Phosphate Neutre de Calcium, *Fr. Cod.*; Precipitated Phosphate of Lime; Phosphate of Calcium; Phosphate Tricalcique, Phosphate de Chaux hydraté, *Fr.;* Calcium Phosphoricum, *P. G.*; Phosphorsaure Kalkerde, Calciumphosphat, *G.;* Fosfato calcico, *Sp.*

Calcium phosphate is found abundantly in nature; the so-called phosphate rock which is found in the southern parts of the United States contains sometimes as much as 90 per cent. of calcium phosphate. It is found also in other minerals such as *apatite* and *phosphorite.* The U. S. V and the Br. 1885 gave a method for preparing calcium phosphate from bone ash. In this process the carefully calcined bones were treated with hydrochloric acid, which dissolved the calcium phosphate of the bones, and the basic phosphate was precipitated from this solution by the addition of ammonia, in a state of minute division. It was then washed to free it from adhering ammonium chloride. The salt thus obtained is, for the sake of distinction, called *bone calcium phosphate.*

The commercial supply of calcium phosphate today is made by a mutual interaction between calcium chloride, sodium phosphate, and ammonium hydroxide at a boiling temperature.

Description and Physical Properties.—" Precipitated Calcium Phosphate occurs as a white, amorphous or microcrystalline, bulky powder, odorless and tasteless; permanent in the air. At an intense white heat the salt fuses without decomposition. Almost insoluble in cold water; partly decomposed by boiling water; almost insoluble in acetic acid, except when freshly precipitated; easily dissolved by hydrochloric or nitric acid; insoluble in alcohol.

" When moistened with silver nitrate T.S., either before or after ignition, the salt acquires a yellow color (distinction from *acid calcium phosphate,* which, after ignition, when moistened with silver nitrate T.S. remains white). For applying tests of identity and of purity, prepare a solution by shaking 2 Gm. of Precipitated Calcium Phosphate with 20 cc. of distilled water, adding nitric acid, drop by drop, until solution is effected, and then sufficient distilled water to make the liquid measure 40 cc. While making this solution, no effervescence occurs on adding the acid (*carbonate*). To a portion of this solution add a slight excess of ammonia water, then an excess of silver nitrate T.S. and afterwards acetic acid, drop by drop, until the excess of ammonia is neutralized; the color of the precipitate changes from white to yellow. Ammonium molybdate T.S. precipitates from the solution yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat, not exceeding 65° C.

" Add to five cc. of the solution, acidulated with nitric acid, 0.5 cc. of silver nitrate T.S.; not more than a slight turbidity is produced (*chloride*). Add to five cc. of the solution, strongly acidulated with nitric acid, 1 cc. of potassium sulphate T.S.; no turbidity appears within fifteen minutes (*barium*). An aqueous solution of Precipitated Calcium Phosphate (1 in 50), obtained by shaking the salt with distilled water, adding hydrochloric acid, drop by drop, and heating until solution is effected, does not respond to the test for heavy metals. Five cc. of a solution of Precipitated Calcium Phosphate in diluted nitric acid (1 in 25), heated with 1 cc. of sulphuric acid until fumes of sulphur trioxide appear, meets the requirements of the Test for arsenic." *N. F.*

"A light, white, amorphous powder, permanent in the air. No odor or taste. Almost insoluble in *water.* Yields the *reactions* characteristic of calcium and of phosphates. Dissolves without residue and without effervescence (absence of carbonate) in *diluted hydrochloric acid* or *diluted nitric acid.* Yields no characteristic *reactions* for barium, ammonium, or silica, and no more than the slightest *reactions* for aluminium or magnesium. *Arsenic limit* 5 parts per million. Its solution in slight excess of *diluted nitric acid* is not rendered more than slightly opalescent by *solution of silver nitrate* (limit of chlorides), or by *solution of barium chloride* (limit of sulphates). Its solution in slight excess of *diluted hydrochloric acid* is not affected by *hydrogen sulphide* (absence of copper and lead), and, on the subsequent addition of excess of *solution of ammonia,* the precipitate produced is quite white (limit of iron)." *Br.*

Joly and Sorel record (*C. R. A. S.,* 1894, 738) the precipitation of tricalcium phosphate by adding crystals of hydrated bicalcium phosphate to boiling water; the acid liquid remaining contains monocalcium phosphate.

Uses.—As the result of an immense amount of investigation it may be regarded as established that the body can synthesize its complex phosphorus-containing tissues from the inorganic phosphates although there is some evidence that the organic forms are used more economically. Evidence is also very strong that for the proper utilization of food phosphorus there is necessary an abundance of calcium in the diet and *vice versa* that phosphoric acid is requisite for normal calcium metabolism. From these facts the conclusion is obvious that calcium phosphate is to be regarded as a useful food-stuff when there is dietetic deficiency in the proportion of these elements. On the basis of these experiments some have jumped to the conclusion that an excess of calcium phosphate in the diet would be beneficial in such diseases as *rickets* where there is a disturbance of bony metabolism. The present evidence indicates, however, that these conditions are due to an inability to properly utilize the requisite compounds in the diet rather than to deficiency of supply. There is at present no convincing evidence that an excess of calcium phosphate is of any great advantage in the treatment of such disorders. If, however, the other factors essential for the utilization of calcium and phosphorus are provided, it seems probable that an excess of these elments in the diet might hasten their deposition in the body. Calcium phosphate should therefore be regarded as a foodstuff, useful in maintaining the health of the tissues or in aiding in the upbuilding of bony and perhaps nervous tissue but, by itself, having little curavite value in disturbances of metabolism. In other words, its rôle is that of a food rather than a medicine. Despite the insolubility of the basic calcium phosphate it is capable of being absorbed from the intestines but, theoretically at least, the more soluble acid phosphate should be more easily absorbed and many authorities prefer, therefore, such preparations as the syrup of calcium lactophosphate in which the lime salt is held in solution by lactic acid.

Dose, ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Liquor Phosphatum Acidus, *N. F.;* Liquor Phosphatum Compositus, *N. F.;* Pulvis Antimonialis, *N. F.;* Syrupus Phosphatum Compositus, *N. F.;* Syrupus Phosphatum cum Quinina et Strychnina, *N. F.*

CALCIUM

CALCIUM

This is the metal characteristic of lime, and, consequently, of all calcareous substances. It was obtained by Matthiessen, in 1855, in masses of the size of a pea, by the electrolysis of calcium chloride with a Bunsen battery. It is, when pure, a yellowish-white crystalline metal, ductile, malleable, with a specific gravity of 1.58 and melting at 760° C. It oxidizes slowly in dry air, more rapidly in moist air, and must therefore be kept under petroleum.

Calcium is a very abundant element in nature, existing in the mineral kingdom chiefly as a carbonate, in the form of limestone, marble, chalk, and calcareous spar; as a sulphate in gypsum and selenite; and as a phosphate and carbonate in the bones and shells of animals.

Therapeutic Action.—Calcium is necessary in the body not only for the stiffening of the bones, but for the correct functioning of nearly all tissues. It has been shown by many investigators that removal of lime salts from muscle tissue, either by washing with sodium chloride solution or by the use of precipitants of calcium, causes spontaneous contractures and eventually paralysis of voluntary muscle fiber, weakens the contractile power of the heart, increases the irritability of the nervous centers both of the brain and spinal cord. See Maxwell (*B. K. Ch.,* 1906, ii, 203). The converse of these reactions are also true; that is, excess of calcium salts lessens irritability of the nerve centers and increases the vigor of the heart beats. The investigations of Roger and Schulmann (*Arch. de Med. Exper. et d'Anat. Path.,* 1916, xxvii, 252) are indicative that the depression of nerve centers in the medulla by large quantities of calcium injected directly into the circulation may cause death through failure of the respiration.

The presence of calcium is essential for the coagulation of the blood; diminution in the proportion of lime salts delays, and the entire absence prevents, clotting. There is also considerable evidence that an increase in the amount of lime salts, at least up to a certain point, will accelerate coagulation.

As a therapeutic agent the lime salts have been used, first, in conditions which are due to deficiency of calcium in the various tissues, and, secondly with the idea that an excess of lime may modify the body functions in a desired direction. Under the first head are various diseases of the bones such as *rickets, osteomalacia,* and *ununited fractures.* There is strong reason to believe that these diseases are due to an inability to utilize calcium rather than to deficiency in the supply. We, therefore, should not expect any great benefit from the use of lime salts in conditions unless the underlying dyscrasia can be corrected; a conclusion that is confirmed by clinical experience. There do occasionally occur cases of bony changes due to deficiencies in the calcium intake; the most common and typical example of this is the softening of the teeth in pregnant women due to the excessive demands for lime salts. This type of case is very greatly benefited by the administration of calcium. It may be remarked in this connection that numerous investigators (see Blaterwick and Lang, *J. Bi. Chem.,* 1922, lii, and Sherman *J. Bi. Chem.,* 1922, liii, 375) have shown that the bodily needs for this element can be derived from an exclusively inorganic source.

In 1909 MacCallum and Voegtlin (*J. Ex. M.,* xi, 118) showed that the convulsive disorder which follows removal of parathyroid bodies is associated with a great reduction of the amount of calcium, both in the blood and in the brain, and that the convulsions could be temporarily controlled by the administration of calcium chloride. This has led to the theory that the disease *tetany* is due primarily to a deficiency of lime in the nerve centers and consequently to a use of salts of this element in the treatment of these convulsions.

As nerve sedatives, the salts of lime have been used in various convulsive diseases as *tetany* and *epilepsy* (Ohlmacher,, *J. A. M. A.,* 1910, liii, 527). Because of the relationship between calcium and phosphorous metabolism (see *Calcium Phosphate*), the lime salts have also been used for their general tonic effects on the nervous system. The administration of large doses of the metal prevents the inflammatory reaction of the conjunctiva to irritants such as abrin or oil of mustard Mayer, (*M. M. W.,* 1910) attributed this fact to the lessened permeability of the walls of the capillary blood vessels, but Nagai and Ito concluded that calcium chloride stimulates phagocytosis. As antiphlogistics the salts of lime have been used in *serum sickness,* inflammation of the serous membranes, as *pleur-*

isy or *peritonitis* (Blum, Press. Med., xxx, 221) in *asthma* and *hay fever.* Whether the value of calcium chloride in *tuberculous enteritis* is to be attributed to its antiphlogistic action or to the effect on the intestinal muscles is as yet uncertain. It may be noted in this connection that although it has been used to a considerable extent in pulmonary *tuberculosis* its value is not established.

Concerning the clinical value of lime salts in *hemorrhage* there has been so much difference of opinion that it is impossible to draw positive conclusions. (For literature see Cohen, *A. I. M.*, 1911, xxiv, 834).

It should be noted in connection with the therapeutic use of calcium that many of the results reported have been from intravenous or hypodermic injections; although the view at one time advanced that inorganic salts of lime would be precipitated in the alimentary canal as insoluble carbonates, and hence not be absorbed, has been shown to be incorrect, the mere fact that the salts are absorbed after oral administration does not establish their therapeutic usefulness. The observations of Dennis and Minot (*J. Bi. Chem.*, 1920, xli, 357), of Howland and Kramer (*Amer. J. Dis. of Children,* 1921, xxii, 105) and others indicate that it is impossible to cause any notable increase in the proportion of lime in the blood by giving the drug by mouth, probably because elimination is more rapid than alimentary absorption. On the other hand, there is considerable evidence that when the blood calcium is subnormal sometimes the administration of lime salts by the mouth will cause an increase.

CALENDULA. N. F.

CALENDULA Calend. [Marigold]

Marigold, Mary-bud, Holligold; Fleurs de Tous les Mois, Souci, *Fr.;* Ringelblume, Todtenblume. Goldblumen, *G.;* Calendula, *Sp.*

"Calendula consists of the dried ligulate florets of *Calendula officinalis* Linné (Fam. *Compositæ*). Calendula contains not more than 2 per cent. of foreign organic matter." *N. F.*

An annual, ornamental herb with spatulate or oblanceolate leaves having toothed margins and terminal flower-heads of yellow to orange-colored ray- and disk-florets. *French* or *African Marigold,* so called, is very frequently substituted for the official drug. It is the *Tagetes patula* L., and *T. erecta* Linn., both of Mexico. The flowers are readily distinguished by the scales of the involucre being united to form a tube, and by the slender, flattish achenes being crowned with a few chaffy or awned scales. The broadly strap-shaped ray-florets are toothed, and of a light or deep orange color sometimes striped with red. Latour and Magnier de la Source isolated from African marigold a yellow crystalline substance, *quercetagetin,* which Perkin examined and gave the composition $C_{15}H_{10}O_8$ (*P. J.*, 1902, 294.) The odor is much stronger in the fresh than in the dry flowers, and on exposure to light, the orange-red or yellow color fades.

Description and Physical Properties.—"*Unground Calendula.*—Florets from 15 to 25 mm. long, yellow- or orange-colored, 1- to 3-toothed, 4- to 5-veined, margin nearly entire, the short hairy tube occasionally enclosing the remnant of a filiform style and bifid stigma. Odor slight, somewhat heavy; taste slightly bitter, faintly saline.

"*Powdered Calendula.*—Light yellow to orange-yellow; a few characteristic, non-glandular hairs, consisting of a double row of thin-walled, more or less collapsed cells with a 1- or 2-celled apex, and up to 0.950 mm. long; elongated epidermal cells with thin, somewhat wavy walls, a striated surface, and containing irregular chromoplasts and oil-like globules, the latter coalescing when mounted in chloral hydrate T.S.; pollen grains, more or less spherical, with numerous spinose projections, three-pored, and up to 0.045 mm. in diameter; tracheæ about 0.009 mm. in width with spiral or annular markings, prisms or rosettes of calcium oxalate from 0.002 to 0.006 mm. in diameter." *N. F.*

It contains traces of a volatile oil, a bitter principle, and an amorphous tasteless substance called *calendulin* (discovered by Geiger most abundantly in the flowers) which swells up in water and is considered by Berzelius as analogous to bassorin, though soluble in alcohol.

Uses.—In the days of therapeutic darkness *calendula* was thought to be medicinally active, but it has no virtues beyond that of a feeble aromatic. Both the leaves and the flowers were used; but the latter were preferred, and were usually administered in the recent state in the form of tea. It has also been used as a local application in various inflamed conditions of the skin or mucous membranes and even as a stimulant to *wounds* and *ulcers.*

Dose, from fifteen to sixty grains (0.9–3.9 Gm.).

Off. Prep.—Fluidextractum Calendulæ, *N. F.;* Tinctura Calendulæ, *N. F.*

CALUMBA. U. S. (Br.)

CALUMBA Calumb. [Columbo]

"Calumba is the dried root of *Jateorhiza palmata* (Lamarck) Miers (Fam. *Menispermaceæ*). Columba yields not more than 2.5 per cent. of acid-insoluble ash." *U. S.* "Calumba Root is the root of Jateorhiza Columba, *Miers,* cut in transverse slices and dried." *Br.*

Calumbæ Radix, *Br.;* Calumba Root; Radix Columbo; Colomba, *U. S.* 1850; Racine de Colombo, *Fr.;* Colombo, *Fr. Cod.;* Radix Colombo, *P. G.;* Kolombowurzel, *G.;* Colombo, *It.;* Colombo, Raiz de colombo, *Sp.;* Kalumbo, *Port.;* Calumb, *Mozambique.*

Calumba is official in nearly all pharmacopœias. The difference in botanical origin as given in the definition in the U. S. and British Pharmacopœias is merely one of synonymy, as *J. palmata* (Lamarck) Miers is merely another name for *J. Columba* Miers. There is considerable confusion in the spelling of both the generic and specific names: *Jateorhiza* is sometimes spelled *Jateorrhiza,* and the specific name is usually given as *Calumba* and not *Columba.*

Jateorhiza palmata is a diœcious climbing plant, with a short fibrous rhizome bearing numerous thick fusiform roots. The stems are twining, cylindrical, hairy and simple in the staminate plant, being branched in the pistillate plant. The leaves, which stand on rounded, glandular, hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each running into one of the lobes. The flowers are small and inconspicuous, and arranged in solitary axillary racemes, which in the staminate plant are compound, in the pistillate simple, and in both plants are shorter than the leaves.

The Calumba plant is indigenous to Mozambique, on the southeastern coast of Africa, where it grows wild in great abundance in the thick forests extending from the sea many miles into the interior. It is more particularly abundant in the region between the Zambezi and Rovuma. (*Ap. Ztg.,* 1912, p. 147.) The root is dug up in March, when dry weather prevails. From the base of the rhizome numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old rhizome is rejected.

The plant is said to be cultivated both in Africa and the East Indies for the sake of its root, which under the name of *Calumb* is used in dyeing.

Calumba is sent from the Portuguese dominions in southeastern Africa into India, whence it goes into general commerce. At one time, when thought to be a product of Ceylon, it was supposed to have derived its name from Columbo, a city of that island, but a much more probable derivation is from the African name of the root above given. (See Lloyd's history of columbo root, *West. Drug.,* 1898, 8.)

Description and Physical Properties.—"*Unground Calumba.*—Circular or oval discs, attaining a diameter of 10 cm. and seldom exceeding 2 cm. in thickness, or longitudinal or oblique slices, attaining a length of 30 cm.; the edge brown and roughly wrinkled, the cut surfaces yellowish-brown or grayish-yellow and indistinctly radiate in the region of the dark cambium; often depressed in the central portion; fracture short and mealy; odor slight; taste slightly aromatic and very bitter.

"*Structure.*—A thick corky layer of small cells with yellowish walls; a starch-bearing parenchyma layer with a few characteristic stone cells scattered singly or in small groups; numerous, narrow wood bundles distinct and separated by broad, starch-bearing medullary rays; phloem portion consisting of sieve tissue with cells mostly collapsed; xylem portion of tracheæ and wood-fibers frequently in small groups separated by starch-bearing parenchyma, especially in the inner portion.

"*Powdered Calumba.*—Greenish-brown to grayish-yellow; starch grains numerous, mostly single, occasionally 2- to 3-compound, the individual grains from 0.003 to 0.085 mm. in length, ovoid, ellipsoidal, frequently very irregular, slightly lamellated, with an excentral linear x-shaped or branching cleft; stone cells few, with irregularly thickened, strongly lignified, coarsely porous walls and often containing one or more prisms of calcium oxalate up to 0.030 mm. in length, or numerous sphenoidal microcrystals; fragments with tracheæ few, the latter with reticulate thickenings or bordered pores, and associated with wood-fibers having long, oblique, slit-like pores and few lignified wood parenchyma having large simple pores." *U. S.*

The drug is described in the British Pharmacopœia as follows: "Cork thin, brownish and wrinkled; cortex thick, yellowish and separated by a dark line from the greyish wood, in which the parenchymatous tissue is largely developed and the vessels arranged in narrow elongated groups. In the cortex, in transverse section, numerous isolated sclerenchymatous cells with yellow, irregularly thickened walls enclosing small prismatic crystals of calcium oxalate; in the wood, vessels with yellow reticulated walls. The parenchymatous cells of both wood and cortex filled with starch grains, which are irregularly ovoid in outline, from 20 to 70 microns in length and exhibit a conspicuous, excentric, radiate or cleft hilum." *Br.*

According to the U. S. P. microscopical description, it is inferred that the calcium oxalate crystals occur only in the stone cells. Tunmann (*Ph. Zentralh.,* 1906, p. 1069) asserts that the crystals are distributed throughout the woody portion of the root as well as in the bark, and outlines a method for readily demonstrating their presence.

Along with the disks are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow, slightly greenish color internally, but covered with a brownish, wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the center; and is often marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest color, are most compact and uniform, and least worm eaten.

The odor of calumba is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is easily pulverized. The powder is greenish, becoming browner with age, and deepening when moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities.

The crude drug, as well as the powder, is liable to be attacked by insects if kept for any length of time. This can be guarded against by thoroughly drying the drug, keeping it in a dry place, and adding either carbon tetrachloride or chloroform.

Adulterations.—Formerly the high price of calumba led to its frequent adulteration, especially, it is said, with the roots of the *white bryony,* and of *Frasera carolinensis* or *American calumba,* and with the stem of *Coscinium fenestratum,* the *columbo wood* or *false columbo* of Ceylon. According to Stolze of Halle, the American calumba can be readily detected by the fact that while the tincture of true calumba is not affected by ferric sulphate or sesquichloride, and yields with tincture of galls a dirty precipitate, the tincture of Frasera becomes dark green with the former and is not affected by the latter reagent. *Coscinium fenestratum,* a bitter tonic used in Ceylon, is at once to be distinguished by its being a stem, not a root. At present, owing to its great cheapness, calumba root seems to be very rarely adulterated (see *P. J.,* 1901, 502, and Dec., 1904), although a specimen of calumba yielded, on incineration, 16 per cent. of ash. Holmes believes that the fictitious drug is the overground portion of *Jateorhiza palmata,* while Wardleworth believed that the drug is a product of *Tinospora Bakis* (A. Rich.) Miers which is used in Senegal as an antiperiodic.

Constituents.—Calumba differs from most vegetable drugs in not containing tannin and can therefore be combined with iron salts without precipitation. It contains, besides about one-third of its weight of starch, a small proportion of volatile oil, salts of calcium and potassium, ferric oxide, and silica. Wittstock, of Berlin, afterwards isolated a neutral principle, which he called *columbin.* This crystallizes in beautiful transparent quadrilateral prisms of the formula $C_{28}H_{30}O_9$, is without odor, and is extremely bitter. It is but very slightly soluble in water, more soluble in alcohol, ether, or chloroform, and imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It melts at 182° C. It is converted by boiling in alkaline solution into *columbic acid.* It is obtained by exhausting calumba by means of alcohol of the sp. gr. 0.835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days until crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother waters still contain a considerable quantity of columbin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution to crystallization.

Alessandri (*P. J.,* 1882) found in this root an alkaloid which he called columbine, which probably, however, was a mixture of principles. According to the researches of Gunzel (*A. Pharm.,* 1906, ccxliv, p. 257) and of Feist and Sandstede (*A. Pharm.,* 1918, cclvi, p. 1) there are present in calumba three alkaloids: *calumbamine, jateorhizine* (*jatrorrhizine*) and *palmatine.* Although they were unable to isolate these bases in a free state they formed the following iodides: calumbamine $C_{21}H_{22}O_5NI$; jatrorrhizine $C_{20}H_{20}O_5NI$; palmatine $C_{21}H_{22}O_4NI$.

The presence of berberine was asserted by Alessandri and also Bocchiola (*Y. B. P.,* 1891, 162), but has been denied by more recent investigators. The proportion of alkaloid ranges between 2.5 and 3 per cent. Haensel (*P. J.,* 1904, 216) obtained from calumba a volatile oil which exists in very small quantities (0.00568 per cent.). It has a peculiar odor and bitter taste.

There can be little doubt that both columbin and the alkaloids contribute to the remedial effects of calumba. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by infusion of galls, and by solutions of lead acetate and subacetate, but the bitterness is not affected.

Uses.—Biberfeld (*Z. E. P. T.,* 1909, vii) has shown that all the alkaloids of calumba root are depressant to the central nervous system and especially to the respiratory center; palmatine indeed exceeds morphine in its respiratory toxicity; columbamine and jateorhizine increase intestinal tonus. Despite these findings, however, it is improbable that calumba has any medical virtue aside from that of a mild bitter, free from astringency. It is useful in functional atonic conditions of the digestive organs, especially with other tonics, aromatics, or cathartics. A favorite remedy of the late George B. Wood for the cure of a disposition to the accumulation of *flatus* in the bowel was an infusion made with half an ounce of calumba, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in doses of a wineglassful three times a day. By the natives of Mozambique it is used in *dysentery* and various other diseases.

Dose, of the powder, from ten to thirty grains (0.65–2.0 Gm.), which may be repeated three or four times a day.

CALX. U. S., Br.

LIME [Calcium Oxide, Quicklime]

"Lime contains, when freshly ignited to constant weight with a blast, not less than 95 per cent. of CaO. It loses not more than 10 per cent. of its weight on ignition. Preserve it in air-tight containers in a dry place." *U. S.*

"Lime, CaO, is calcium oxide obtained by calcining marble." *Br.*

Calcii Oxidum, Calcium Oxydatum; Calcaria Usta, Calx Viva, Calx Usta, Oxydum Calcicum; Burned Lime; Oxyde de Calcium, *Fr. Cod.;* Chaux, Chaux vive, *Fr.;* Calcaria Usta, *P. G.;* Aetzkalk, Kalk, Gebrannter kalk, *G.;* Ossido di calcio, Calce, *It.;* Cal viva, *Sp.*

Preparation.—Lime is prepared by calcining, by a strong heat, some form of the native carbonate. The carbon dioxide is thus expelled, and the lime remains. When the lime is intended to be of a high degree of purity, it may be obtained from Iceland spar. For the purpose of the arts it is procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way it is generally impure, being of a grayish color, and containing alumina, silica, ferric oxide, and occasionally a little magnesia and manganese oxide.

The official lime of the United States and British Pharmacopœias is usually the lime of commerce. It may be obtained in a purer form by exposing pure white marble, broken into small fragments, in a covered crucible, to a full red heat for three hours, or until the residue, when slaked and suspended in water, no longer effervesces on the addition of hydrochloric acid.

Description and Physical Properties.—"Hard, white or grayish-white masses or granules, or a white powder. It is odorless. One Gm. of Lime is soluble in 840 cc. of water at 25° C., and in 1740 cc. of boiling water. It is soluble in glycerin and in syrup, but is insoluble in alcohol.

"When moistened with water, Lime becomes heated, and is gradually converted into a white powder (calcium hydroxide or slaked lime). When this is mixed with about 3 or 4 times its weight of water, it forms a smooth magma (milk of lime). Water, when agitated with Lime, becomes alkaline to litmus paper. Slake 1 Gm. of Lime with 20 cc. of distilled water and add acetic acid until the lime is dissolved: the resulting solution responds to the reactions for calcium.

"Slake 1 Gm. of Lime, thoroughly mix it with 50 cc. of water, and decant the greater portion of the milky liquid: the addition of an excess of diluted hydrochloric acid to the residue does not cause more than a slight effervescence (*carbonate*). Slake 5 Gm. of Lime, then mix it with 100 cc. of distilled water, followed by hydrochloric acid, drop by drop, with agitation until solution takes place: the resulting solution after boiling and cooling should be acid and should not deposit more than 0.05 Gm. of insoluble matter. Ignite a portion of Lime to constant weight in a tared platinum crucible, with a blast lamp: the loss in weight does not exceed 10 per cent. (*volatile substances*). Dissolve 0.5 Gm. of Lime in 10 cc. of diluted hydrochloric acid, neutralize with ammonia T.S., completely precipitate the calcium by adding ammonium oxalate T.S., and then filter: the filtrate on evaporation and ignition leaves not more than 0.004 Gm. of fixed residue (*magnesium, other alkali earths, or alkalies*).

"**Assay.**—Ignite about 1 Gm. of Lime to constant weight over a blast lamp, weigh accurately, dissolve in 20 cc. of diluted hydrochloric acid, cool the solution, dilute with distilled water to 100 cc., and mix well. Transfer 20 cc. of this solution to a 200 cc. volumetric flask, and proceed with the assay as directed under *Calcii Carbonas Præcipitatus.* Each cc. of tenth-normal oxalic acid corresponds to 0.002804 Gm. of CaO.

"Preserve in air-tight containers, in a dry place." *U. S.*

"Compact whitish masses, which readily absorb water. When rather less than their weight of water is added, the masses swell and fall to powder with the development of much heat. The powder obtained by this process of slaking, when shaken with *water,* gives, after filtration, a clear alkaline solution which yields the *reactions* characteristic of calcium. Yields not more than the slightest characteristic *reactions* for iron, silica, carbonates, chlorides, or sulphates. *Arsenic limit* 5 parts per million." *Br.*

Lime has a sp. gr. of 3.15 to 3.40. Its solubility in water is greatly increased by the addition of sugar or glycerin. (See *Liquor Calcis Saccharatus.*) It is distinguished from the other alkaline earths by forming a very deliquescent salt (*calcium chloride*) by reaction with hydrochloric acid, and a sparingly soluble one with sulphuric acid.

All acids, acidulous, ammoniacal, and metallic salts, borates, alkaline carbonates, and astringent vegetable infusions are incompatible with it.

Uses.—Lime acts externally as an escharotic, and was formerly applied to ill-conditioned *ulcers.* The *lime ointment* of Spender is made by incorporating four parts of washed slaked lime with one part of fresh lard and three parts of olive oil, previously warmed together. Mixed with potassium hydroxide, lime forms *Potassa cum Calce,* official in the U. S. P., 1890. As an internal remedy, it is converted into hydroxide and this is administered in solution. (See *Liquor Calcis.*)

Calcium oxide may cause a form of caustic poisoning like that of the hydroxides (see under *Potassii Hydroxidum*), but it is less common than either sodium or potassium. Local burns from quick-lime are, however, not infrequent. In the treatment of these the first thing is to neutralize the caustic by washing with a weak acid, preferably a dilute solution of acetic acid; after-treatment is on the same lines as other burns.

CALX CHLORINATA. U. S., Br.

CHLORINATED LIME Calx Chlorin.

"Chlorinated lime is a product resulting from the action of chlorine upon calcium hydroxide, and yields not less than 30 per cent. of available chlorine [Cl]. Preserve it in air-tight containers, in a cool and dry place." *U. S.* "Chlorinated Lime is obtained by exposing slaked lime to the action of chlorine gas until absorption ceases." *Br.*

Chlorinated Calcium Oxide, Calx Chlorata, *U. S.* 1890; Chloride of Lime, Hypochlorite of Lime, Calcium Hypochlorosum; Calcicus Chloruratus; Chloris Calcicus, Chloruretum Calcis, Calcis Chloridum, Calcii Hypochloris, Calcium hypochlorite, Bleaching Powder; Chlorure de Chaux sec, *Fr. Cod.;* Poudre de Tennant ou de Knox, *Fr.;* Calcaria Chlorata, *P. G.;* Chlorkalk, Bleichkalk, *G.;* Cloruro di calcio, *It.;* Hipoclorito calcico clorurado, *Sp.*

This compound, originally prepared as a bleaching agent in 1798 by Tennant, of Glasgow, is now enormously used both in the arts and in medicine. (For a process of manufacture see *U. S. D.,* 19th ed., p. 267.)

It is made on a large scale by passing chlorine vapors into calcium hydroxide. A series of horizontally placed drums or cylinders provided with revolving endless screws receive the dry calcium hydroxide, which, from its entering the top cylinder until discharged from the bottom one, meets a continuous stream of chlorine gas going in the opposite direction. According to Lunge's investigations, the best temperature for the absorption of chlorine by calcium hydroxide is 40° to 45° C.; from pure calcium hydroxide a bleaching powder of 43 per cent. active chlorine can be produced, in which case allowance for 4 per cent. of moisture in the hydroxide is made.

Several electrolytic processes for the decomposition of sodium and potassium chlorides have been introduced in recent years, whereby caustic alkali on the one hand and chlorine on the other hand are produced. The chlorine liberated is almost entirely utilized in the manufacture of bleaching powder. Large quantities are thus produced at present at Niagara Falls.

Description and Physical Properties.—"A white, or grayish-white, granular powder, having the odor of chlorine. It becomes moist and gradually decomposes on exposure to air and when in such condition must not be used. It is partially soluble in water and in alcohol, the insoluble portion settling readily when mixed with water.

"Shake 1 Gm. of Chlorinated Lime with 50 cc. of distilled water, and filter: the filtrate at first turns litmus paper blue and then bleaches it. Dissolve 0.5 Gm. of Chlorinated Lime in 5 cc. of diluted acetic acid: an abundance of chlorine gas is evolved and only a slight residue remains undissolved. Ammonium oxalate T.S. added to this solution yields a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid.

"**Assay.**—Transfer to a mortar, about 4 Gm. of Chlorinated Lime, accurately weighed in a tared weighing bottle, using 50 cc. of distilled water. Triturate thoroughly, and pour the mixture into a graduated liter flask, rinsing the mortar with distilled water to make 1000 cc. Stopper the flask, and allow it to stand for ten minutes. Shake thoroughly, add to 100 cc. of the mixture 1 Gm. of potassium iodide and 5 cc. of acetic acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003546 Gm. of available chlorine (Cl).

"Preserve in air-tight containers, in a cool, dry place." *U. S.*

"A dull white powder with a characteristic chlorinous odor, becoming moist and gradually decomposing on exposure to air. Partially soluble in *water.* The solution yields the *reactions* characteristic of calcium and of chlorides, and evolves chlorine copiously upon the addition of an acid. 0.5 gramme of Chlorinated Lime, mixed with 1.5 grammes of *potassium iodide* dissolved in 200 millilitres of *water,* gives, when acidified with 6 millilitres of *hydrochloric acid,* a reddish solution, which requires for decolorisation not less than 42.3 millilitres of *N/10 solution of sodium thiosulphate,* corresponding to not less than 30 per cent. of available chlorine." *Br.*

When perfectly saturated with chlorine it dissolves almost entirely in water. When exposed to heat, it gives off oxygen and some chlorine, and is converted into calcium chloride. It is incompatible with the mineral acids, carbon dioxide, and the alkaline carbonates. The acids evolve chlorine copiously, and the alkaline carbonates cause a precipitate of calcium carbonate. (See *Liquor Sodæ Chlorinatæ.*) It is said that strong mineral acids, when not used in excess, liberate only hypochlorous acid; dry carbon dioxide at normal temperature does not set free any chlorine, but at moderately elevated temperature drives off almost all the chlorine.

Chlorinated lime is an oxidizing agent, the oxygen being derived from water, the hydrogen of which unites with the chlorine to form hydrochloric acid. It has a powerful action on organic matter, converting sugar, starch, cotton, linen, and similar substances into formic acid, which unites with the calcium. It also acts energetically on the volatile oils, including oil of turpentine, producing chloroform.

Chlorinated lime constantly becomes weaker on exposure to air and light, giving off chlorine or hypochlorous acid, probably through the influence of the atmospheric carbon dioxide, which sets them free by combining with the calcium, after the compound has become damp through the absorption of moisture.

Composition.—The composition of chlorinated lime is represented by the formula $CaOCl_2$, and it was formerly supposed to be a direct compound of lime with chlorine. This view, however, is not consistent with its reactions, for when distilled with diluted nitric acid it readily yields a distilate of aqueous hypochlorous acid, and when treated with water it is resolved into calcium chloride and hypochlorite, the latter of which may be separated in crystals by exposing the filtered solution to a freezing mixture, or by evaporating it in a vacuum over oil of vitriol and leaving the dense frozen mass to thaw upon a filter. A solution of calcium chloride mixed with hypochlorite then passes through, and feathery crystals remain on the filter. These are very unstable, but consist, when recently prepared, of hydrated calcium hypochlorite, $Ca(OCl)_2.4H_2O$. This seems, at first sight, to show that the bleaching powder is a mixture of calcium chloride and hypochlorite, formed according to the equation.

$$2CaO + Cl_4 = CaCl_2 + Ca(ClO)_2$$

but if this were its true constitution the powder when digested with alcohol ought to yield a solution of calcium chloride containing half the chlorine of the original compound, which is not the case. Its constitution is, therefore, better represented by the formula $Ca\left\{\begin{matrix}Cl\\OCl\end{matrix}\right.$ suggested by Odling, this molecule being decomposed by water into chloride and hypochlorite in the manner just explained, and yielding with diluted nitric acid or sulphuric acid a distillate containing hydrochloric and hypochlorous acids,

$$CaCl(OCl) + 2HNO_3 = Ca(NO_3)_2 + HCl + HClO$$

(Lunge and Schaeppi, *A. J. P.*, 1881; Lunge and Naef, *B. Chem. G.*, 1883.) Lunge and Bachofen (*Zeit. angew. Chem.*, 1893, 326) have determined the specific gravities of chlorinated lime solutions at 15° C. (See *Proc. A. Ph. A.*, 1894, 579.)

Impurities and Tests.—Chlorinated lime may contain a great excess of lime, from imperfect impregnation with the gas. This defect will be shown by the large proportion insoluble in water. If it contain much calcium chloride, it will be quite moist, which is always a sign of inferior quality. When long and insecurely kept, it deteriorates from the gradual formation of calcium chloride and calcium carbonate. Much of the chlorinated lime on the market is greatly below the official requirements in available chlorine, probably because of its instability. Several methods have been proposed for determining its bleaching power, which depends solely on the proportion of loosely combined chlorine. The oxidation of an arsenous acid solution is largely used in practice. Lunge (*B. Chem. G.*, 1886, p. 869) has also proposed to use hydrogen dioxide (H_2O_2) solution for the valuation of bleaching powder. The two solutions liberate oxygen in exactly equal amount. This is measured in a nitrometer.

A valuable reagent for the qualitative detection of free or available chlorine, capable of showing a positive reaction in water containing as small proportion as 0.01 part of chlorine to the million, has been described in the *Amer. Journ. of Pub. Health* for 1916, p. 160, by the Committee on Standard Methods of Water Analysis. It consists of a solution of 1 Gm. of orthotolidin in 1000 cc. of 10 per cent. hydrochloric acid. In the presence of chlorine this reagent gives a yellow or greenish-yellow color. It may also be used for quantitative determinations of free or available chlorine by using colorimetric methods of comparison, and permanent comparison standards may be made from copper sulphate solutions according to the directions given in the article.

The following is the test given in the British Pharmacopœia: "0.5 gramme of Chlorinated Lime, mixed with 1.5 grammes of *potassium iodide* dissolved in 200 millilitres of *water,* gives, when acidified with 6 millilitres of *hydrochloric acid,* a reddish solution, which requires for decolorisation not less than 42.3 mllilitres of *N/10 solution of sodium thiosulphate,* corresponding to not less than 30 per cent. of available chlorine." *Br.*

This is similar in principle to the U. S. P. assay method previously described. In this process iodine is separated by the chlorine in equivalent quantity, and imparts color to the liquid, which is removed by the sodium thiosulphate, by forming colorless compounds with the iodine, and the quantity required for this purpose measures the quantity of iodine, and consequently that of the chlorine, present in the chlorinated solution. (See *Sodii Thiosulphas.*)

Chlorinated lime acts exclusively by its chlorine. It should be carefully kept from contact with the air and organic substances, which cause rapid loss of chlorine, and the modern method of putting it up for ordinary use in hermetically sealed zinc boxes is a great convenience. R. C. Bicknell examined commercial chlorinated lime put up in boxes for available chlorine. He found the top layers usually deficient in strength, but in the interior from 30 to 35 per cent. of chlorine. Some of the packages assaying 30 per cent. of chlorine were more than a year old. (*A. J. P.*, 1886, p. 593.) Investigations made more recently show that variations in the percentage of chlorine are found in the chlorinated lime put up in packages. See Puckner, Stephens, and Harding (*Proc. A. Ph. A.*, 1898, 905). All acids, even carbonic, disengage it, and, as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection; but the stronger acids disengage the chlorine far more readily, and among these sulphuric acid is the most convenient. Accordingly, the powder may be dissolved in a very dilute solution of this acid, or a small quantity of the acid may be added to an aqueous solution ready formed, if a more copious evolution of chlorine be desired than that which takes place from the mere action of the carbon dioxide of the atmosphere.

Uses.—As the therapeutic virtues of chlorinated lime depend largely upon the chlorine gas which is liberated from it, it may be well to discuss in this place the effects of chlorine. This gas is an extraordinarily powerful germicide, according to Geppert (*B. K. W.*, 1890), 0.03 per cent. being sufficient to kill the highly resistant anthrax spores in two minutes. It should be noted, however, that in the absence of moisture its germicidal power is comparatively slight. Gaseous chlorine has been used for the purpose of disinfecting inclosed spaces, such as ships' holds, but although highly efficient, if properly used, has largely passed out of vogue. Not only is chlorine actively germicidal, but because of its oxidizing effect decomposes hydrogen sulphide and other malodorous substances, thereby acting as a deodorant. For the same reason it is a powerful bleaching agent and destructive to many kinds of organic matters.

Chlorinated lime possesses desiccant, disinfectant, deodorizant, and bleaching powers. As a bleaching agent it is widely used in the arts. As regards its antibacterial properties it probably ranks, except the salts of mercury and silver, as the most active germicide official. Bolton has shown that one part in two thousand of chlorinated lime is sufficient to destroy the viability of the typhoid bacillus within two hours, and that a one per cent. solution would kill the anthrax spores in the same time. Niessen (*Z. Hyg.*, vii, p. 62) finds that a one per cent. solution can be relied on to destroy either typhoid or cholera germs in the feces within ten minutes, while Stokes and Hatchel (*J. A. M. A.*, li, p. 1505) report that chlorinated lime equivalent to from 0.4 to 1.5 parts per million of chlorine killed ninety per cent. of the bacteria in drinking water.

The most important use of chlorinated lime is as a disinfectant. For the purpose of destroying disease germs in urine, feces, sputa, or similar matters it is, taking all things into consideration, the best of all chemical agents. Its advantages are its relative cheapness, the promptness and certainty of its action, and its oxidizing power which enhance its penetration into organic masses. For this purpose sufficient chlorinated lime to equal about two parts for each hundred of excreta should be intimately mixed and the mixture allowed to stand for one or two hours in an agate-ware, china, or glass receptable. A solution of one pound of chlorinated lime to a bucketful of water makes an excellent disinfectant for washing the walls and floors of dissecting rooms, privies, docks, and other places with offensive effluvia, not only for its germicidal, but especially for its deodorizing effect. The same solution is also serviceable for sterilizing dishes and other utensils which have been used by patients with infectious diseases. Because of its decolorizing effect it is not a suitable agent for the sterilization of colored goods or clothing.

Chlorinated lime may be advantageously applied to the purpose of purifying polluted water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. The water must afterwards be exposed for some time to the air, and allowed to settle, before it is fit to drink. For water not grossly polluted it is sufficient to use about one part of available chlorine per million parts of water. This destroys all pathogenic bacteria and communicates scarcely any taste or odor to the water. It is now used on a large scale for this purpose by many municipalities or gaseous chlorine is used directly.

For more directly medicinal purposes chlorinated lime has been used in solution externally as an application to ill-conditioned *ulcers, burns, chilblains,* and the *itch,* also as a gargle in *angina* and as a disinfectant and deodorizant mouth wash in *ulcerated gums* and similar conditions. Binz (*B. K. W.*, 1909) recommends an ointment containing from 10 to 20 per cent. of chlorinated lime for the treatment of *chilblains* and of *erysipelas.* This ointment must be made with petrolatum as the true fats rapidly render the salts inert. For external application the solution may be made of the strength of from one to four drachms (3.9–15.5 Gm.) to a pint (500 cc.) of water. Vincent (*Press. Mèd.*, 1914, Oct. 8) has had success in the treatment of *hospital gangrene* by powdering the wound with a mixture of 1 part of chlorinated lime to 10 parts of boric acid. From one to four drachms of the powder added to a pint of water, and the solution filtered, will form a liquid within the limits of strength ordinarily required. For the cure of *itch,* Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion, or constantly by wet cloths. When applied to *ulcers,* their surface may be covered with lint dipped in the solution. When used as an ointment to be rubbed upon *scrofulous enlargements* of the lymphatic glands, this may be made of a drachm of the chloride to an ounce of lard. Riehl (*W. M. W.*, 1907) has confirmed the findings of Calmette regarding the value of calcium hypochlorite as an antidote for *snake bite.* For this purpose ten cc. (2½ fluidrachms) of a 1 per cent. solution should be immediately injected in the neighborhood of the wound. (See also *Liquor Sodæ Chlorinatæ Chirurgicalis.*)

It has been used occasionally internally, in *adynamic dysentery, typhus fever,* and various other *low diseases* but the solution of chlorinated soda is usually preferable. The dose internally is from three to six grains (0.2–0.4 Gm.), dissolved in one or two fluidounces (30–60 cc.) of water, filtered and sweetened with syrup. It should never be given in pills. (See also *Chlorine,* Part II.)

Dose, four grains (0.26 Gm.).

Off. Prep.—Liquor Calcis Chlorinatæ, *Br.;* Liquor Sodæ Chlorinatæ, *U. S., Br.;* Liquor Sodæ Chlorinatæ Chirurgicalis, *U. S.*

CALX SULPHURATA. Br.

SULPHURATED LIME

"Sulphurated Lime is a mixture consisting chiefly of calcium sulphide and calcium sulphate. It may be obtained by heating calcium sulphate with carbon. Contains not less than 50 per cent. of calcium sulphide, CaS." *Br.*

Calcii Sulphidum Crudum, *U. S. IX,* Crude Calcium Sulphide; Calcium Sulphuratum, Calcii Sulphidum; Calcaria Sulfurata, Hepar Sulphuris Calcareum, Hepar Calcis; Sulphide of Calcium; Sulfure de Chaux, *Fr.;* Kalkschwefelleber, *G.*

This preparation has been dismissed from the U. S. P. but is recognized by the Br. No process is at present official. The process of the U. S. P. VIII is as follows:

"Exsiccated Calcium Sulphate, in fine powder, *seventy grammes;* Charcoal, in fine powder, *ten grammes;* Starch, *two grammes.* Mix the powder thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small, glass-stoppered vials." *U. S. VIII.*

By subjecting a mixture of seven parts of calcium sulphate and one part of charcoal to a red heat, in a covered crucible, carbonic oxide is formed, and calcium sulphide is produced,

$$CaSO_4 + 2C = CaS + 2CO_2$$

A less convenient method is to pass hydrogen sulphide over red-hot lime, but if the lime be pure a better product is insured. A *phosphorescent calcium sulphide* used in luminous paints is prepared by igniting calcium carbonate and sulphur and activating with one-thousandth of its weight of bismuth.

Properties.—Crude calcium sulphide is "a greyish-white powder with an odor of hydrogen sulphide; taste nauseous. Yields the *reactions* characteristic of calcium. When 0.8 gramme is mixed in a stoppered flask with a cold solution of 1.4 grammes of *copper sulphate* in 50 millilitres of water, and, after the addition of a little *hydrochloric acid,* the mixture is heated to a temperature approaching that of ebullition, well shaken for ten minutes, and then filtered, the filtrate gives a red color with *solution of potassium ferrocyanide* (presence of a due proportion of sulphide)." *Br.* The U. S. IX described it as "a pale gray or yellowish powder, having a faint odor of hydrogen sulphide and a nauseous and alkaline taste. It gradually decomposes on exposure to moist air. Crude Calcium Sulphide is very slightly soluble in cold water; more readily soluble in boiling water with partial decomposition; readily dissolved by solutions of ammonium salts; insoluble in alcohol. When Crude Calcium Sulphide is decomposed by diluted acetic acid, hydrogen sulphide is evolved and a residue of calcium sulphate and carbon frequently remains. The filtered solution yields with ammonium oxalate T.S. a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

Calcium sulphydrate, or *calcium hydrosulphide,* $Ca(SH)_2$, the compound produced when calcium sulphide is dissolved in water is also formed when hydrogen sulphide is passed into milk of lime as long as it is absorbed. It may be obtained in the form of a paste of a greenish-gray color, and exhales a strong odor of hydrogen sulphide.

Assay.—The U. S. IX gave the following method for determining the proportion of pure CaS present: "Introduce about 0.2 Gm. of Crude Calcium Sulphide, accurately weighed, into a glass-stoppered bottle or flask; add 50 mils of distilled water, mix, and quickly introduce 30 mils of a 10 per cent. ammonium chloride solution and immediately stopper the flask. Agitate the contents for a few minutes, add quickly 20 mils of a 10 per cent. cadmium chloride solution, immediately insert the stopper and again agitate well for a few minutes. Then add 5 mils of acetic acid, heat the mixture on a water bath for fifteen minutes, decant the supernatant liquid through a filter, agitate the remaining precipitate with 10 mils of diluted acetic acid, transfer the precipitate to the filter and wash with 10 mils of diluted acetic acid. Return the filter and precipitate to the original flask, add 50 mils of tenth-normal iodine V.S. and 20 mils of a mixture of equal valumes of hydrochloric acid and water. Stopper the flask and agitate it vigorously for a few minutes, and then titrate the excess of iodine with tenth-normal sodium thiosulphate V.S. It shows not less than 55 per cent. of CaS. Each mil of tenth-normal iodine V.S. used corresponds to 0.003607 Gm. of CaS. Each gramme of Crude Calcium Sulphide corresponds to not less than 152.5 mils of tenth-normal iodine V.S." *U. S. IX.*

Uses.—Sulphide of lime owes its therapeutic virtues chiefly to the hydrogen sulphide which is evolved during its decomposition. This gas is locally irritant and actively poisonous, not only to bacteria, but to more highly organized forms of life. Because of this latter property calcium sulphide is a useful agent in the treatment of various parasitic *skin diseases,* such as *scabies, ring-worm,* etc. Because of its local stimulating action it is also employed in various other skin diseases, such as *acne.* Its use as a depilatory depends upon its solvent powers towards keratin. It should be stirred up with enough water to form a paste and spread in a thin layer over the area from which it is desired to remove the hair. At the end of fifteen minutes it is removed with a wet sponge, the hair generally coming away at the same time. See Brayton. (*J. A. M. A.,* April 16, 1898.) For the treatment of skin diseases it may generally be employed in strengths of from twenty to thirty grains to the ounce. It is very widely used in the form of *Vleminckx's solution.* (*Liquor calcis sulphurati,* N. F.) Pusey (*J. A. M. A.,* 1920, lxxiv, p. 97) recommends the latter in full strength for removal of *warts.*

The older dermatologists used calcium sulphide largely as an internal remedy in the treatment of *furunculosis* and *acne,* but it is not evident how it can prove beneficial. In recent years it has also been recommended as a chemical antidote for mercuric chloride (see *Hydrargyri Chloridum Corrosivum*).

Dose, one-fourth to one grain (0.015–0.06 Gm.).

CAMBOGIA. U. S.

GAMBOGE Cambog.

"Gamboge is the gum-resin obtained from *Garcinia Hanburyi* Hooker filius (Fam. *Guttiferæ*). Gamboge contains not more than 1 per cent. of foreign organic matter, and yields not more than 1 per cent. of acid-insoluble ash, and not less than 65 per cent. of alcohol-soluble extractive." *U. S.*

Cambogia, *Br.* 1898; Gambogia, *U. S. Pharm.* 1870; Gummi-resina gutti; Gummi Guttæ; Gutta Gamba, Cambodia; Pipe Gamboge; Gommegutte, *Fr. Cod.;* Gutte, *Fr.;* Gutti, *P. G.;* Gummigutt, *G.;* Gumma gotta, *It.;* Gutagamba, Gomo-resina Guta, *Sp.*

Several plants belonging to the family of *Guttiferæ,* growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure and bears a close resemblance to gamboge; but it is only from a particular tree that the official gum-resin is procured. The name Cambogia (of which Gamboge is a corruption) appears to have been derived from the fact that it originally came from the kingdom of Cambodia, now a part of French Indo-China. Many years ago Hanbury who had received from Singapore specimens of the gamboge plant cultivated in that island, and derived from Siam, found that the plant approached very near to the *Garcinia Morella* of Desrousseaux, from which it could be distinguished only by its pedicellate flowers and classified it as *G. Morella,* var. *pedicellata.* Sir Joseph Hooker, however, determined (*Journ. Linn. Soc.,* xiv, 480) that the var. *pedicellata* is a distinct species, differing from *G. Morella* in having not only its flowers pedicellate, but also its leaves more ovate and much larger, and its fruit larger; he very properly gave it the specific name of *Hanburii.*

G. Hanburii is a tree reaching a height of fifty feet found in a limited district including Cambodia, southern Cochin-China and the islands and sea coast of the Gulf of Siam, where it is known as "*Ton Rong.*"

Gamboge is said to be procured in Siam by breaking off the leaves and shoots of the tree; the juice, which is contained in ducts or latex vessels in the bark, issues in drops, and being received in suitable vessels, gradually thickens, and at length becomes solid. Jamie, of Singapore, states that incising the trunk and larger branches is often practised. The juice is frequently received into the hollow joints of the bamboo, and the water expelled by mild continuous heat. In this way the so-called pipe gamboge is formed, the contraction during drying causing the cylinders to be hollow. According to Beckett, Siam gamboge is obtained only from trees of not less than ten years of age and during the rainy months, from June to October, by cutting long, spiral grooves into the bark and collecting in hollow bamboos the sap which trickles down in a viscous stream. (*Kew Bulletin,* 1895.)

The name *gummi gutta,* by which gamboge is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. Although the medicinal properties of this gum were known to the Chinese as far back as the thirteenth century it was first brought to Europe by the Dutch, about the middle of the seventeenth century. We import it mainly from Singapore.

Indian Gamboge, formerly recognized by the Br. Add. under the name of *Cambogia Indica,* is obtained from the *Garcinia Morella* Desrouss. *Ceylon gamboge,* derived from *G. pictoria* Roxb., is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Christison were in flattish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. It resembles coarse gamboge, and was identical in composition. In Ceylon it is used as a pigment and purgative. (Christison.) *New Caledonian gamboge,* derived from *Garcinia collina* Vieil, is described by Heckel and Schlagdenhauffen as very similar in its appearance and reactions to ordinary gamboge; its color is, however, deep orange. A white crystalline compound, which when heated beyond 235° C. produced pyrocatechin, was found in it, and marked the point of difference between it and other varieties of gamboge. (*Rép. de Pharm.,* 1893, 193.)

Varieties.—The best gamboge is in cylindrical rolls, from two to five centimeters in diameter, sometimes hollow in the center, sometimes flattened, often folded double, or agglutinated in masses so that the original form is not always easily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange color, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, slightly adhering to the surface. In this form the drug is sometimes called *pipe gamboge.* Another variety is imported under the name of *cake* or *lump gamboge.* It is in irregular masses weighing a kilo or more, often mixed with sticks and other impurities, containing many air-cells, less dense, less uniform in texture, and less brittle than the former variety, and breaking with a dull and splintery instead of a shining and conchoidal fracture. The worst specimens of this variety, as well as of the cylindrical, are sometimes called by the druggists *coarse gamboge*. They differ, however, from the preceding only in containing a greater amount of impurities. Indeed, it would appear from the experiments of Christison that all the commercial varieties of this drug have a common origin, and that cake or lump gamboge differs from the cylindrical only in the circumstance that the latter is the pure concrete juice, while to the former, farinaceous matter and other impurities have been added for the purpose of adulteration. The inferior kinds of gamboge may be known by their greater hardness and coarser fracture; by the brownish or grayish color of their broken surface, which is often marked with black spots; by their obvious impurities, and by the green color which their decoction, after cooling, gives with tincture of iodine (starch). When pure, the gum-resin is completely dissolved by the successive action of ether and water, so that the amount of residue left by any specimen treated in the manner just spoken of indicates approximately the measure of the adulteration.

Description and Physical Properties.—"*Unground Gamboge.*—Cylindrical pieces, frequently hollow at the center, from 2 to 5 cm. in diameter, up to 20 cm. in length, longitudinally striate, grayish orange-brown; fracture brittle, conchoidal, presenting a smooth, rather dull, orange-red surface; odorless; taste acrid.

"*Powdered Gamboge.*—Bright yellow; when mounted in chloral hydrate T.S., nearly all the particles slowly dissolve leaving but a few fragments of vegetable tissues and a very few or no starch grains.

"When rubbed with water, Gamboge yields a yellow emulsion which becomes darker and almost transparent upon the addition of ammonia T.S. The emulsion does not turn green upon the addition of iodine T.S. (*starch*).

"**Assay.**—Proceed as directed under alcohol-soluble extractive." *U. S.*

From the brilliancy of its color, gamboge is highly esteemed as a pigment. It has no odor, and little taste, but, after remaining a short time in the mouth, produces an acrid sensation in the fauces. Its sp. gr. is 1.221. If the proportion of starch be unduly large the emulsion will yield a blue, instead of a green, reaction with iodine.

It is a gum-resin, without volatile oil. Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. In one experiment, out of 100.8 parts be obtained 74.2 of resin, 21.8 of gum, and 4.8 of water. The gum is quite soluble in water, and of the variety denominated arabin. Flückiger, however, says that the gum is not identical with gum arabic, as its solution does not redden litmus, and is not precipitated by neutral lead acetate, nor by ferric chloride, nor by sodium silicate or biborate. The resin of gamboge, formerly known as *gambogic acid,* is soluble in alkaline solutions—from which it may be precipitated by acids—in alcohol, ether and other organic solvents. From it have been separated α-, β-, and *γ-garcinolic acids.* By fusing purified gamboge resin with potassium hydroxide, Hlasiwetz and Barth (*Ann. Ch. Ph.*, cxxxviii, 61) obtained acetic and other acids of the same series, together with phloroglucin, *pyrotartaric acid,* and *isouvitinic acid,* $COOH.C_6H_4.CH_2COOH$. Sassarini found gamboge to contain the following constituents: 1. Gum anallogous to arabin. 2. Volatile oil, consisting of terpene and a camphor 3. Isouvitinic and acetic acids. 4. A phenol ester. 5. Resin. 6. Methyl alcohol and some higher homoogues. 7. A liquid having a fruity odor resembling aldehyde or acetone. He believes phloroglucin found by others to be a decomposition product. (*Ann. di Chim. Farm.*, 1897.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resin is very slowly deposited. It yields its resinous ingredient to alcohol, forming a golden-yellow tincture, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Ether dissolves about four-fifths of it, taking up only the resin. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; the solution when diluted deposits a yellow sediment. The color, acrimony, and medicinal power of gamboge are thought to reside in the resin. Hirschsohn gives a method for detecting gamboge in mixtures in *Ph. Z. R.*, xxiv. (*A. J. P.*, 1885.)

Uses.—Gamboge is a powerful, drastic, hydragogue cathartic, so very apt to produce nausea and vomiting and much griping when given in the full dose that it is almost never employed except in combination with other cathartics. In large quantities it is capable of causing fatal effects, and death has resulted from a drachm. The full dose is from two to six grains (0.13–0.4 Gm.), which in cases of *tenia* has been raised to ten or fifteen grains (0.65–1.0 Gm.). It may be given in pill or emulsion, or dissolved in an alkaline solution. In the dose of five grains (0.32 Gm.) the resin is said to produce copious watery stools, with little or no uneasiness. If this be the case, it is probable that, as it exists in the gum-resin, its purgative property is somewhat modified, by the other ingredients.

Dose, one to three grains (0.06–0.2 Gm.).

CAMPHORA. U. S., Br.

CAMPHOR Camph.

"A dextrorotatory ketone [$C_9H_{16}CO$] obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier (Fam. *Lauraceæ*)." *U. S.* "Camphor, $C_{10}H_{16}O$, is a white crystalline substance obtained from Cinnamomum Camphora, *T. Nees and Eberm.*, purified by sublimation." *Br.*

Gum Camphor; Camphora Officinarum; Camphre du Japon *Fr. Cod.;* Camphre droit, *Fr.;* Camphora, *P. G.;* Kampher, Kampfer, Campher, *G.;* Canfora, *It.;* Alcanfor, *Sp.*

The name of camphor has been applied to various concrete, white, odorous, volatile products, found in different aromatic plants, and resulting probably from chemical change in their volatile oil. But camphor proper is derived mainly from two plants, the *Cinnamomum Camphora* (L.) of Nees or *Laurus Camphora* of Linnæus (Fam. *Lauraceæ*) and the *Dryobalanops Camphora* Colebrooke (Fam. *Dipterocarpaceæ*); the former of which yields our official camphor, the latter, the Borneo or Baras camphor, a product much valued in the East, but unknown in the commerce of this country and of Europe. Borneo camphor resembles true camphor, but is distinguished by being heavier than water and not being volatile at ordinary temperatures. On treatment with nitric acid it is converted into true camphor. In California, *Ramona stachyoides, Artemisia trifolium* and *Artemisia frigida* are grown for camphor.

The camphor tree (*Cinnamomum Camphora*) is an evergreen which sometimes attains great size, having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth, greenish bark. Its leaves, which stand alternately upon long foot-stalks, are ovate-lanceolate, entire, smooth and shining, ribbed, of a bright yellowish-green color on their upper surface, paler on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a purple, one-seeded drupe, resembling that of the cinnamon. The camphor tree is a native of China, Japan, and adjacent portions of Eastern Asia, but is capable of cultivation in most sub-tropical countries, where the minimum winter temperature is not below –6.6° C., and the summers are warm. It thrives in Formosa, Madagascar, South Africa, Argentina, Egypt, Canary Islands, Southern Europe, and is being cultivated in India, Ceylon, the Federated Malay States, Luzon, Burma, Florida, Southern California, and Texas. The chief obstacle to its cultivation seems to be the extreme slowness of growth of the tree, and the corresponding slowness of returns from the investment. For an account of cultivation in Florida see *D. C.*, Sept., 1902; also True and Hood, *Proc. A. Ph. A.*, 1909, p. 719.

In Japan and Formosa the drug is obtained chiefly from the root, trunk and branches by the process of sublimation, but in the American plantations the leaves and small twigs are utilized, thus avoiding injury to the trees. Only the older trees are employed; indeed, it is said that a tree must be fifty years old before it should be considered available. In the province of Tosa, in Japan, the method of obtaining camphor, as reported by Dewey (Circular 12, *U. S. Dept. of Agric.*, Div. of Botany), is as follows: "The trees are felled and the trunk, larger limbs, and sometimes the roots are cut into chips with a sharp, concave adze. The fresh chips are placed in a wooden tub about 40 inches high and 20 inches in diameter at the base, tapering towards the top like an old fashioned churn. The perforated bottom of the tub fits tightly over an iron pan of water on a furnace of masonry. The tub has a tight fitting cover, which may be removed to put in the chips. It is surrounded by a layer of earth about 6 inches thick to aid in retaining a uniform temperature. A bamboo tube extends from near the top of the tub into the condenser. This consists of 2 wooden tubs of different sizes, the larger one right side up, kept about two-thirds full of water from a continuous stream which runs out of a hole in one side. The smaller one is inverted with its edge below the water, forming an air-tight chamber. This air chamber is kept cool by the water falling on the top and running down over the sides. The upper part of the air chamber is sometimes filled with clean rice straw, on which the camphor crystallizes, while the oil drips down and collects on the surface of the water. In some cases, the camphor and oil are allowed to collect together on the surface of the water, and are afterwards separated by filtration through rice straw or by pressure. About 12 hours are required for distilling a tubful by this method. Then the chips are removed and dried for use in the furnace, and a new charge is put in. At the same time the camphor and oil are removed from the condenser. By this method 20 to 40 pounds of chips are required for 1 pound of crude camphor." In China the comminuted plant is said to be first boiled with water until the camphor adheres to the stick used in stirring, when the strained liquor is allowed to cool, and the camphor which concretes, being alternated with layers of earth, is submitted to sublimation. In the island of Formosa, where the camphor tree abounds, the chips are heated in a rough still. This is usually composed of a furnace surmounted with a trough or similar rude vessel, which is protected by clay. In this reservoir the chips are placed, with water upon them, and a perforated board luted upon the top; on this are set earthenware pots. A fire having been lighted, steam rises through the chips and carries the camphor with it to deposit it in the pots. The crude camphor is taken to the towns in baskets and then put into large vats, with holes in the bottom, through which an oil escapes called *camphor oil,* much used by the Chinese for medicinal purposes. It is said that of recent years hydraulic pressure is largely substituted for drainage.

Crude camphor is of a pinkish color and of a softer consistency than the refined. It is purified by mixing it with about one-fiftieth of its weight of quicklime and heating in an iron vessel, first to a temperature of about 100° C. which drives off the water and volatile oil. Afterwards the vessel is connected with a suitable receiver and heated to a temperature of 175° to 200° C. which causes the camphor to sublime, the vapors condensing in the receiver. It is refined both in Japan and in the United States.

Oil of Camphor.—Two substances occur in commerce under the name of oil of camphor: The one derived from the *Cinnamomum Camphora,* known as the *Formosa* or *Japanese oil of camphor,* and formerly official under the name of *Oleum Camphoræ* in the U. S. P.; the other the product of *Dryobalanops aromatica,* the *East India oil of camphor,* not occurring in American and European commerce.

Oil of camphor, as found in our markets, is a colorless fluid or of a light yellowish-brown color, having a strong odor like that of camphor, a bitterish camphorous taste and a specific gravity, according to Wm. Procter, of 0.940. It acts strongly on polarized light, and is dextrogyrate. Yoshida (*A. J. P.,* 1886, p. 99) found in it besides two terpenes an oxygenated oil, which constituted half of the crude oil, to which he gave the formula $C_{10}H_{16}O,H_2O$, and calls it *camphorogenol.* Schimmel & Co., of Leipsig, have since extracted *safrol* commercially from the Japanese oil of camphor, and give a different account of its composition. They state (*Schim. Rep.,* 1888) that it contains camphor, safrol, eugenol, a sesquiterpene, $C_{15}H_{24}$, and possibly terpinol. They do not consider Yoshida's camphorogenol to be a distinct substance.

Japanese oil of camphor varies in tint from the colorless transparency of water, through pale straw and yellow, to almost black. The specific gravity varies from 0.898 in the colorless oil to 0.990 in the very dark. The oil seems to vary greatly in the amount of camphor it contains, much of it having nearly all the solid principle removed before exportation. The odor is distinctly camphoraceous, with a peculiarity that suggests the odor of sassafras. It is said by Peter MacEwan to differ from the Formosa oil in its behavior towards nitric acid. If half a drachm of the acid be allowed to act upon half a drachm of Japanese oil, and then diluted with half a drachm of water, a crimson color will be produced. The Formosa oil so treated yields a milky color with a scarcely perceptible green shade; hydrochloric acid gives with each oil a salmon color, more marked, however, with the Japanese oil. For further details, see *P. J.,* vols. xv, xvi, and *J. C. S.,* Oct., 1885. The oil is said to be used in Japan for the preparation of Chinese ink and varnishes, and for burning. As a diluent for artists' colors it is useful because its capacity for dissolving resins is greater than that of oil of turpentine and similar liquids.

The oil of camphor has properties similar to those of camphor, but more stimulant, and is especially applicable to affections of the stomach and bowels in which an anodyne and stimulant impression is indicated, as *flatulent colic* and *spasmodic cholera.* It may also be used externally, as a rubefacient and anodyne liniment, diluted with soap, liniment, or olive oil, in *local rheumatism* and *neuralgic pains, bruises, sprains,* etc. The dose is two or three minims (0.12–0.2 cc.).

The *Dryobalanops oil of camphor* is said to be found in trees too young to produce camphor, and is supposed to constitute the first stage in the development of this substance, as it occupies the cavities in the trunk which are afterwards filled with the camphor. The chief constituent of it is a peculiar volatile oil, which is termed *borneene;* it is isomeric with oil of turpentine, $C_{10}H_{16}$, and holds in solution borneol and resin. By fractional distillation this oil may be separated into two portions, the one more volatile than the other, but not differing in composition.

Commercial History.—The commerce of the world is supplied with camphor chiefly from China, Japan, and Formosa, the great bulk of the product coming from the latter island. After the annexation of Formosa by the Japanese, that government, led by the unnecessary destruction of the camphor trees of the island, the inferiority of the camphor obtained, and the waste of the processes employed, and especially by the desire for revenue, made a governmental monopoly of the camphor trade which went into operation in 1900. The camphor is sold by the Japanese government through a single London firm from whose agencies refiners in different parts of the world buy it by contract for a year at a time. Camphor is now cultivated on a commercial scale in Florida. According to an article in the *Oil, Paint, and Drug. Rep.,* Feb. 26, 1917, p. 18, one grove in Florida produces 40 tons of crude camphor annually.

Camphor is imported into the United States in tin-lined or zinc-lined cases. Crude camphor comes to the United States from Hongkong and Foochow, China, and from Formosa; refined camphor from Shanghai, China and from Formosa; synthetic camphor from Germany.

Sumatra Camphor. Borneo Camphor. Dryobalanops Camphor. Bhimsaim Camphor. Baros Camphor, Borneol.—This camphor is produced in the islands of Sumatra and Borneo from *Dryobalanops Camphora* Coleb. This tree is very large, often exceeding one hundred feet in height, with a trunk six or seven feet in diameter and ranks among the tallest and largest trees in India. It is found in Sumatra and Borneo, and is abundant on the northwest coast of the former island. The camphor exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old. The only method of ascertaining whether a tree contains camphor is by incision. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed by means of sharp-pointed instruments. It is stated that the masses are sometimes as thick as a man's arm, and that the product of a medium-sized tree is nearly eleven pounds; of a large one, double that quantity. The trees which have been wounded and left standing often produce camphor seven or eight years afterwards. Ida Pfeiffer states, in her *Second Journey Round the World,* that the camphor is also found in a concrete state under the bark and is swept down with long brooms. The whole tree is pervaded more or less by the camphor or the oil. The wood retains a fragrant odor, and, being on this account less liable to the attacks of insects, is highly esteemed for carpenter work.

Borneo camphor resembles in appearance ordinary camphor, but has, according to Christison, a specific gravity of 1.009. Its odor is also distinctly different from that of camphor. It usually pulverizes without the addition of alcohol, is less volatile than ordinary camphor and does not sublime on the interior of the bottles in which it is kept. It fuses at 206° C. and boils at 212° C.; is dextrogyrate; has a formula of $C_{10}H_{17}(OH)$; and by the action of boiling nitric acid is converted into common camphor. It does not reach European commerce, being largely consumed in the Batta provinces, especially in funeral rites; and any that is exported is brought up at enormous prices for China, where it is preferred for embalming purposes on account of its being less volatile than the ordinary drug.

Borneo camphor is also produced in Johore, a province of the Malay peninsula, where it is sold in four qualities. The first is composed of transparent crystals, generally a quarter of an inch and upwards in length; the second of brown crystals, inferior in size; the third of powdery, coherent and slightly grayish colored crystals, which resemble Japanese camphor; the fourth quality is brownish, pulverulent, and looks like seashore sand.

Ngai camphor is yielded by the *Blumea balsamifera* DC. (Fam. *Compositæ*), a shrub from 5 to 6 feet high which occurs in India, China, Formosa, Philippines, etc. The crude drug is known to the Chinese as *ngai-fêu,* and when refined in Canton as *ngai-p'ien.* About ten thousand pounds annually are exported from Canton. The refined camphor in appearance, odor, hardness, specific gravity, and volatility agrees almost precisely with Borneo camphor. According to Plowman, it has the chemical composition of Borneo camphor, but differs from it in its alcohol solution, being lævogyrate, and in being converted by boiling nitric acid into a substance thought to be identical with the stearopten of *Chrysanthemum Parthenium* Pers. Another species of Blumea, the *B. grandis,* a weed growing from 6 to 8 feet high, is said to yield a camphor identical with the Japanese product.

The physiological action of *Borneo* and *Ngai camphor* and of artificial *borneol* has been studied by R. Stockman (*J. P.,* 1888, ix) who finds that the action of the three substances is practically identical and closely resembles that of true camphor. The results obtained by A. Lapin (*Med. Age,* 1894, xii) confirm those of Stockman, and show that in its proper dose the drug increases the energy of the heart, and that in frogs it is an especial motor nerve paralyzant.

Artificial Camphor.—Camphor can be made artificially by the oxidation of *camphene,* $C_{10}H_{16}$, with chromium trioxide mixture. Camphene is obtained from either *pinene hydrochloride* (so-called artificial camphor) or from bornyl chloride by treatment with alcoholic potash, and is a solid crystalline mass, fusing at 49° C. In the patented process of Nathan Thurlow, camphor is made by submitting oil of turpentine to the action of anhydrous oxalic acid in steam-jacketed reaction tanks. The liquid mass, containing *pinyl oxalate* and *pinyl formate,* is then distilled in the presence of an alkali with live steam, the resultant products being camphor, Borneol camphor, and certain oily products, which are separated from one another and purified by a somewhat complicated process. It is stated that turpentine yields in this process from 25 to 35 per cent. of its weight, and that oil of lemon and other essential oils, and terpenes are obtained as secondary products. This artificial camphor is either optically inactive or has a very slight dextrorotation, but in general physical properties exactly resembles natural camphor. So far, however, it seems to be difficult to work the process upon a large scale and the artificial product has had little effect upon the general camphor market. Camphor can also be produced from isoborneol, by the action of oxidizing mixtures. The method patented in France, which is said to yield from 95 to 100 per cent. of camphor, consists in suspending ten kilogrammes of isoborneol in ten kilogrammes of benzol, and adding ten kilogrammes of potassium permanganate dissolved in one thousand liters of water, until the color of the permanganate is discharged. The camphor produced is separated by distillation and crystallized from petroleum benzin. Some pine needle oils and also Siberian oil of turpentine contain large proportions of bornyl acetate; the remaining terpenes may be converted into bornyl formate by the action of formic acid and a dehydrating agent. The mixed bornyl esters may then be converted into very pure camphor, free from chlorine compounds. A study of natural and synthetic camphor by Houseman giving complete review of all processes for producing the synthetic article and illustrated with structural formulas is found in *A. J. P.*, 1915, p. 49.

While some writers have used synthetic camphor as a substitute for a natural variety with asserted good results, the facts that Pari and Bruni found the laevo-camphor thirteen times more toxic than the dextro-camphor and that the synthetic product is optically inert emphasizes the necessity of careful research before the artificial camphor can be considered therapeutically equivalent to the natural. (For literature see Borsich, *Ph. Centralh.*, 1920, lxi, p. 403.)

Camphor, $C_{10}H_{16}O$, and borneol, $C_{10}H_{18}O$, are classified together as belonging to the group called in general *camphors*, which are related to the *terpenes*, and are considered to be oxidation products of these.

Borneol is an alcohol, yielding esters when heated to about 200° C. with organic acids. It is a secondary alcohol, and therefore contains the group CH.OH linked to a more complex group. Secondary alcohols by oxidation yield ketones, by the change of the CH.OH group to CO. Common camphor bears this relation to borneol, and is therefore considered as a ketone, and can be formed from borneol by the action of mild oxidizing agents. The action of metallic sodium, on the other hand, upon common camphor, $C_{10}H_{16}O$, yields borneol, $C_{10}H_{18}O$.

Description and Physical Properties.—"White, translucent, tough masses or granules. It has a penetrating, characteristic odor, and a pungent, aromatic taste. It is readily pulverizable in the presence of a little alcohol, ether, or chloroform. It slowly volatilizes at ordinary temperatures. One Gm. of Camphor is soluble in about 800 cc. of water, 1 cc. of alcohol, 0.5 cc. of chloroform, and in 1 cc. of ether, at 25° C. It is freely soluble in carbon disulphide, petroleum benzin, and in fixed or volatile oils.

"Specific gravity: about 0.990 at 25° C. Camphor melts between 174° and 177° C. The specific rotation $[a]_D$ of Camphor, determined at 25° C. in a solution containing 10 Gm. of Camphor in 100 cc. of alcohol and using a 200 mm. tube, is between $+41°$ and $+42°$.

"A solution of Camphor in petroleum benzin (1 in 10) is clear (*water*). Gradually heat about 2 Gm. of Camphor: it sublimes without carbonization and without leaving more than 0.05 per cent. of non-volatile matter. Wind the end of a copper wire into a spiral about 6 mm. in diameter and 6 mm. in length, and hold it in a non-luminous flame until it glows without coloring the flame green. Dip the hot spiral in the Camphor, ignite, allow it to burn outside of the flame, and then bring the spiral into contact with the lower, outer edge of a non-luminous flame: not even a transient green color is imparted to the flame (*chlorinated products*).

"Preserve in well-closed containers, in a cool place." *U. S.*

"Colorless, transparent crystals or crystalline masses of tough consistence; also in rectangular tablets or in pulverulent masses known as 'flowers of camphor.' Penetrating and characteristic odor; taste pungent and somewhat bitter, followed by a sensation of cold. Specific gravity about 0.995. Melting point about 175° C. Soluble in about 700 parts of *water*, in 1 part of *alcohol* (90 per cent.), in 0.25 part of *chloroform*, and in 4 parts of *olive oil;* very soluble in *ether*. Burns readily with a bright smoky flame, volatilises even at ordinary temperatures, and sublimes without residue when heated. Forms a liquid when triturated with chloral hydrate, menthol, phenol, thymol, and certain other substances. A solution of 5 grammes in sufficient *alcohol* (90 per cent.) to produce 20 millilitres exhibits at 15.5° C. an *optical rotation* of about $+10°$ (distinction from synthetic camphor)." *Br.*

Camphor has a peculiar, strong, penetrating, fragrant odor, and a bitter, pungent taste, and a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, brittle, and yet possessed of a tenacity which renders its reduction to a fine powder very difficult unless its cohesion be overcome by the addition of a minute proportion of alcohol, ether, chloroform, glycerin, essential or fatty oils, or other liquid for which it has an affinity. It may be obtained in powder by pulverizing with an equal weight of sugar, by precipitating the tincture with water, or by grating and afterwards sifting it, or by sublimation. A still better plan is to dissolve camphor in one and a half parts of alcohol, and pour this solution with stirring into four parts of water. Collect the precipitate, wash with water, and dry. By noting the quantity of camphor used, the amount left dissolved in the diluted alcohol can be calculated, and this solution used in making tincture. The fracture of camphor is shining, and its texture crystalline. Its sp. gr. varies from 0.9857 to 0.996. When thrown in small fragments upon water, it assumes singular circulatory movements, which cease upon the addition of a drop of oil; and this property has been applied to the detection of grease in liquids, a very small proportion of which is sufficient to prevent the movements. Its volatility is so great that, even at ordinary temperatures, it is wholly dissipated if left exposed to the air. When it is confined in bottles, the vapor condenses on the inner surface, and, in large bottles partially filled, sometimes forms, after long standing, large and beautiful crystals. It melts at 175° C., boils at 204° C., and, in closed vessels, sublimes unchanged. When allowed to concrete slowly from the state of vapor, it assumes the form of hexagonal plates. It is not altered by air and light. It readily takes fire, burning with a brilliant flame, with much smoke, and without residue.

Leo and Rimbach find that the solubility of camphor in pure water is 1 part in 598. The solubility in water falls with rise of temperature. (*J. Soc. Chem. Ind.*, xxxviii, 1919, 738A.) Carbon dioxide increases the solvent power of water, as also does the spirit of nitrous ether. Ordinary alcohol will take up 75 per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states that 100 parts of alcohol, of the sp. gr. 0.806, dissolve 120 parts of 10° C. It is soluble without change in ether, the volatile and fixed oils, strong acetic acid, and diluted mineral acids, and is extremely soluble in chloroform. Nitric acid on prolonged boiling with camphor oxidizes it into *camphoric acid,* $C_{10}H_{16}O_4$ (see Part II), and *camphoronic acid,* $C_9H_{14}O_6$. Schwanert's *camphresinic acid,* $C_{10}H_{14}O_{12}$, is, according to Kachler, a mixture of these two. Sulphuric acid in the proportion of ten parts to one gives, when heated with camphor, an oil isomeric with camphor, boiling at 200° C., and yielding a solid camphor when distilled repeatedly over potassium hydroxide. Sulphuric acid, in the proportion of four to one with camphor, gives, according to Chautard, a volatile product which he calls *camphrene,* and to which Schwanert gives the formula $C_9H_{14}O$. Kachler (*Ann. Ch. Ph.,* clxiv, p. 90) considers, however, that camphrene is only *phorone* (a condensation product of acetone) with slight impurities. Alcoholic potassium hydroxide solution heated with camphor gives a derivative called *campholic acid,* $C_{10}H_{18}O_2$, a white solid, fusing at 95° C., and boiling at 250° C. Resins unite with camphor, forming a soft, tenacious mass, in which the odor of the camphor is sometimes almost extinguished, and frequently diminished; and a similar softening effect results when it is triturated with the solid fats. Exposed to a strong heat, in closed vessels, camphor is resolved into carbonic acid gas and hydrocarbons, among which cymol is especially to be recognized.

Genuine camphor is said to be sometimes adulterated with the synthetic, which may be detected by the action of ammonia upon its alcoholic solution, causing a flocculent precipitate, which does not redissolve, and the quantity of which is proportionate to that of the synthetic product in any mixture of the two. (*A. J. P.,* xxxiv, 189.) As a means of distinguishing camphor from the synthetic camphor, J. W. Bailey recommends that a drop of alcohol, holding in solution a little of the camphor to be tested, be allowed to evaporate on the slide of a microscope. The crystals then formed produce, with polarized light, beautiful colors, if of natural camphor, but not, if of the synthetic. (*Neues Repertorium,* xvi, 763, 1867.)

The best test for distinguishing natural and synthetic camphor is by mixing 0.1 Gm. of the suspected substance, on a watch glass with ten drops of a cooled mixture of equal parts of vanillin-hydrochloric acid and concentrated sulphuric acid. Natural camphor first turns green and after five hours' exposure, dark blue; synthetic camphor remains yellow.

Another point of distinction is said to be the fact that the synthetic camphor does not liquefy when triturated with an equal weight of chloral hydrate, while the natural camphor does.

Uses.—Locally camphor is irritant, with probably a benumbing influence upon the peripheral sensory nerves, and somewhat antiseptic. It is absorbed through mucous membranes not very readily, but easily from subcutaneous tissue. It combines in the body with glycuronic acid and is eliminated in this combination by the kidneys. The systemic action of camphor is not well understood. In frogs it is depressant to the spinal cord and produces no motor disturbance except gradually increasing paralysis. In the mammalia, including man, it causes convulsions which are apparently due to an effect upon the motor tract of the brain. It appears also to have some stimulant action upon the intellectual centers and antagonizes the somnifacient drugs. On the other hand, in conditions of nervous excitement it will frequently produce a sensation of quietude. The effects of camphor upon the circulation have been the subject of an immense amount of scientific investigation but with very contradictory results. The majority of authorities have found that the drug increases the force of the cardiac contractions in cold-blooded animals, but in the studies upon warm-blooded animals the results have been so contradictory that it seems impossible to harmonize them. Most investigators have found that camphor does not produce any consistent change in the blood pressure until large doses are given, when it is likely to cause a fall, but on the other hand, Pilcher and Sollman (*J. P. Ex. T.,* 1915, vi, p. 349) have found that in the great majority of cases it causes a definite rise in the blood pressure. While Gottlieb (*Z. E. P. T.,* 1905, ii) and others have obtained evidence of a stimulant action upon the heart muscle of warm-blooded animals, the majority of experimenters have been unable to determine such an effect. (For review of the literature on this subject, see *J. P. Ex. T.,* 1914, v, p. 571.) On the other hand, several investigators present evidence indicating that it has the power of antagonizing certain poisons such as strophanthin, chloral, phosphorus, etc., and the clinical evidence of the stimulating effect of camphor upon the circulation seems incontestable. Marfori (*Rif. M.,* 1918, xxxiv, p. 567) asserts that it is a remedy of great value in *myocarditis* with irregular rhythm; its action, he believes, is due to a stimulation of the nodal system of the heart. Marvin and Soifer (*J. A. M. A.,* 1925, lxxxiii, p. 94) in careful observations on fourteen patients with chronic heart disease, were unable to note any favorable influence of camphor upon either the circulation or general condition of the patient. For reference to the literature on this subject see the paper of Marvin and Soifer. In cases of heart failure whether due to diseases of the heart itself or secondary to infectious fevers, such as *typhoid* or in *pneumonia,* it is, however, highly esteemed by many clinicians.

In pneumonia camphor has been used not only as a cardiac stimulant but with the idea that it inhibits the growth of the pneumococci. While the evidence for this view is strongly suggestive it cannot be considered in any way conclusive. (For review of the literature on this subject see *J. A. M. A.,* 1920, lxxiv, p. 46.)

Aside from its action as a circulatory stimulant camphor is used internally for its calmative influence in *hysteria,* general *nervousness* and *neuralgia.* Whether the effects in these conditions are due to any action other than a psychic influence from the strong taste of the drug, is open to question. It is also employed in the treatment of *serous diarrheas,* its effects being probably due to a local irritant action upon the mucous membrane of the intestines. Externally it is widely employed as a counter-irritant in *sprains, rheumatic affections, bronchitis,* and other inflammatory conditions. It is also employed as a local application, especially in conjunction with menthol or phenol, in inflammations of the upper respiratory tract.

When a profound influence is desired, as in heart failure, it is necessary to give the drug hypodermically. For this purpose from three to five grains may be dissolved in twenty to thirty minims of sterile olive oil. The effect of a single injection lasts usually about two hours. Attention may be called to the fact that solutions of camphor in liquid petrolatum are entirely unsuited for hypodermic administration. Apparently the camphor is not absorbed under these conditions and not only does it fail to produce the desired physiological action but is often followed by serious local inflammatory changes. In nervous diseases it may be given in substance, in capsule, or as the spirit; the water contains so little camphor that it is scarcely more than a vehicle.

Cases of camphor poisoning, chiefly from the accidental ingestion of camphor liniment, have been reported. Benz (*J. A. M. A.,* 1919, lxxii, p. 1217) reports 20 such cases. The most constant symptom observed has been clonic convulsion, usually accompanied with vertigo, more or less mental confusion often amounting to active delirium and sometimes followed with coma. While sometimes the symptoms are very alarming the mortality is very low. The treatment, aside from evacuation of the stomach, is purely symptomatic.

Dose, two to five grains (0.13–0.32 Gm.).

CANELLA. N. F.

CANELLA Canel.

"Canella is the dried rossed bark of *Canella Winterana* (Linné) Gaertner (Fam. *Canellaceæ*). Canella contains not more than 2 per cent. of foreign organic matter." *N. F.*

Cortex Canellæ; Cortex Winteranus Spurius; White Cinnamon; Cassia alba; Jamaica Winter's Bark, Wild Cinnamon Bark; Weisser Zimmt, *G.*

Canella alba Murr. (Fam. *Canellaceæ*).—The Spaniards who noted this bark shortly after the discovery of the West Indies believed, because of its aromatic odor, that it was a species of cinnamon and called it "white cinnamon" (*Canella alba*). The first mention of it was by Clusius in 1605. Subsequently it was confused with Winter's Bark (see Part II).

Canella Winterana is a tree, native of Florida and the Bahama and West India Islands. The bark of the branches, which is the part employed in medicine, is loosened and deprived of its epidermis by beating. After removal from the tree it is dried in the shade. It enters commerce at Nassau, Island of New Providence, West Indies, where it is known as *cinnamon bark,* or as *white wood bark.*

Description and Physical Properties.—"*Unground Canella.*—In quills usually from 1 to 3 cm. long and from 1 to 4 cm. thick, occasionally 2 or 3 times this size, or in irregular fragments of bark, from 1.5 to 5 mm. thick and 2 to 3 cm. wide, the outer periderm mostly removed; outer surface light brownish yellow or pale orange-brown, more or less scaly, with a few very shallow fissures, often more or less reticulate with slight ridges; inner surface pale yellow, somewhat smooth, but showing coarse, longitudinal striæ; fracture short and sharp, pale yellow internally with an irregular, slightly darker band at the center. Odor slight unless the bark is heated, then aromatic, resembling that of cinnamon; taste aromatic, warm, somewhat bitter and mucilaginous.

"*Powdered Canella.*—Light brown to brownish red; numerous, isodiametric, thick-walled stone cells 0.040 to 0.090 mm. in diameter, the walls with simple or branching pores; calcium oxalate in rosettes up to 0.050 mm. in diameter; starch grains simple or 2- to 3-compound up to 0.020 mm. in diameter; oil cells with suberized walls numerous." *N. F.*

Nearly one-fourth the weight of canella is extracted by boiling water but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. Canella bark yields by distillation from 0.75 to 1.25 per cent. of a volatile oil, having an odor resembling that of a mixture of cajeput and clove. It contains benzoyl eugenol; l-pinene; cineol and caryophyllene. The bark yielded to Flückiger 0.74 per cent. of oil. According to John P. Frey, it contains volatile oil, 1.28 per cent.; resin, 8.2 per cent.; mannite, 8 per cent.; ash, 8.9 per cent.; also starch, bitter principle, albumen, and cellulose. (*A. J. P.*, 1884, 1.)

Uses.—Canella is a mild, aromatic tonic, very acceptable to the stomach, and especially as an addition to tonic or purgative medicines. It is scarcely ever prescribed except in combination. Its best known compound is the famous *Pulvis Aloe et Canellæ* (see Part III), commonly known as *Hiera Picra*, literally "*Sacred Bitters*," from the esteem in which it was once held. In the West Indies it is employed by the negroes as a condiment and as an antiscorbutic.

Dose, ten to forty grains (0.65–2.6 Gm.).

Off. Prep.—Pulvis Aloes et Canellæ, *N. F.*

CANNABIS. U. S. (Br.)

CANNABIS Cannab.

"Cannabis is the dried flowering tops of the pistillate plants of *Cannabis sativa* Linné (Fam. *Moraceæ*). Cannabis, in the form of the fluidextract, administered by the mouth to dogs in doses not exceeding 0.1 cc. for each kilogram of body weight of dog, produces a degree of incoördination equivalent to that caused by the same dose of the standard fluidextract of cannabis, prepared as directed below. It contains not more than 10 per cent. of its fruits, large foliage leaves, stems over 3 mm. in diameter, and not more than 2 per cent. of other foreign organic matter. It yields not more than 5 per cent. of acid-insoluble ash, and not less than 8 per cent. of alcohol-soluble extractive." *U. S.* "Indian Hemp consists of the dried flowering or fruiting tops of the pistillate plant of Cannabis sativa, *Linn.*, grown in India; from which the resin has not been removed." *Br.*

Cannabis Indicæ, *Br.;* Hemp, Indian Hemp; Guaza, Ganjah, Herba Cannabis Indicæ; Chanvre, Chanvre de l'Inde, *Fr.;* Indischer Hanf, *G.;* Cañamo, *Sp.;* Marihuana, *Mex.*

For many years the official cannabis was restricted to the drug which was used for centuries in India. The reason for this was that the Indian cannabis was more uniformly active. Recently the Indian Government has placed a high tax on every pound of the drug grown. The result has been that other markets have been sought and the hemp plant has been grown in other parts of Asia, Africa and America. While, of course, much of this material is not equal to that grown in India yet the fact that it can be grown, as shown by experiments, in the United States (see Hamilton, *J. A. Ph. A.*, 1913, ii; 1915, iv, 389) of a very high quality has caused the framers of the U. S. Pharmacopœia to permit the use of a cannabis, no matter where it may be grown, provided it comes up to the biological standard as given in the definition. Physiologically active cannabis is obtained at the present time not only from India, but Africa, Turkey, Turkestan, Asia Minor, Italy, Spain and the United States.

The *Cannabis sativa*, or hemp plant, is a tall, rough annual, from four to sixteen feet or more in height, with erect, branching, angular stem. The leaves are alternate or opposite, and palmately-compound, with five to seven linear-lanceolate, coarsely serrated leaflets. The stipules are subulate. The flowers are axillary and greenish; the staminate in long, branched, drooping panicles; the pistillate in erect, simple catkins. The stamens are five, with long pendulous anthers; the pistils two, with long, filiform, glandular stigmas. The fruit is an ovate achene. The whole plant is covered with a fine pubescence, scarcely visible to the naked eye, and somewhat viscid to the touch. The hemp plant of India has been considered by some as a distinct species, and named *Cannabis indica;* but the most observant botanists, upon comparing it with our cultivated plant, have been unable to discover any specific difference. It is now, therefore, regarded merely as a variety. Pereira states that in the female plant the flowers are somewhat more crowded than in the common hemp, but that the male plants in the two varieties are in all respects the same.

C. sativa is a native of the Caucasus, Persia, and the hilly regions in Northern India. It is cultivated in many parts of Europe and Asia, and largely in our Western States.

The most important commercial varieties of cannabis are the India, American and African. Indian cannabis is obtained from plants grown in various districts of India, chiefly north of Calcutta. The flowering tops are collected when they have taken on a brownish color, the fruits shaken out and the herbage allowed to wilt and then subjected to the rolling and treading process in order to work resinous matter from the stems into the inflorescences. There are two commercial grades of Indian cannabis, viz.: round and flat. The round is prepared by kneading each branch into a cylindrical or rounded mass. The flat grade is kneaded into a compressed flattened form. The color is grayish-brown. The commercial supplies of this variety are imported into the United States from Bombay, India.

American cannabis is yielded by *Cannabis sativa* plants cultivated in various sections of the United States. It occurs on the market in the form of broken segments of the inflorescences and more or less crumpled and broken leaves, varying in color from brownish-green to light brown.

African cannabis from *Cannabis sativa* plants growing in various districts of Africa, comes into the market as broken leaves and flowering-tops of a greenish-brown color.

The fruits or "so-called" seeds, though not now official, have been used in medicine. They are from three to five millimeters long and about two millimeters broad, roundish-ovate, somewhat compressed, of a shining ash-gray color, and of a disagreeable, oily, sweetish taste. For a comprehensive monograph on the morphology of cannabis fruits, as well as their history and chemical composition, see Tschirch, *"Handbuch der Pharmakognosie,"* p. 555. They yield by expression about 20 per cent. of a fixed oil, which has the drying property, and is used in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water form an emulsion, which may be used advantageously in inflammations of the mucous membrane, though without narcotic properties. The seeds are much used as food for birds, as they are fond of them. They are generally believed to be in no degree poisonous; but Michaud relates the case of a child in whom serious symptoms of narcotic poisoning occurred after taking a quantity of them. It is probable that some of the fruit eaten by the child was unripe, as in this state it would be more likely to partake of the peculiar qualities of the plant.

In Hindostan, Persia, and other parts of the East, hemp has long been habitually employed as an intoxicating agent. The parts are the tops of the plant, and a resinous product obtained from it. *Bhang* is the selected, dried and powdered leaves. *Ganjah* or *gunjah* is the tops of cultivated female plants, cut directly after flowering, and formed into round or flat bundles from two to four feet long by three inches in diameter. It is stated that in the province of Bengal great care is taken to eradicate the male plants from the fields before fertilization of the female, and that thereby the yield and quality of the resin is greatly increased. In Bombay this matter is commonly neglected, so that Bengal ganjah is much superior to Bombay ganjah. It is recognized in India that ganjah rapidly deteriorates on keeping, that which is one year old being not more than one-quarter as potent as the fresh drug, while two-year-old ganjah is practically inert and is required by the Indian government to be burned in the presence of excise officers. It is probable, however, that much old ganjah finds its way into the markets of the world.

The method of collection in Baluchistan is to gently rub the dried plant between carpets. The dust which comes off contains the active principle and is known as "rup." The second shaking produces an inferior variety, known as "tahgalim," and the third shaking is known as "ganja." In Nepal the plant is squeezed between the palms of the hands, and the resin scraped off from the hands. These balls, and also masses formed out of resin mechanically separated from the hemp plant are called *charas* or *churrus*. This is the *hashish* or *hasheesh* of the Arabs.

Hashish is also produced in considerable quantities in Persia by rolling and rubbing the flowers, stalks and leaves of hemp on rough woollen carpets and subsequently scraping off with a knife and making into balls or sticks the adherent resinous substance. The carpets are afterwards washed with water and the extract obtained by evaporation sold at a low price.

Momea or *mimea* is a hemp preparation said to be made in Thibet with human fat.

The pistillate plants are much more active than the staminate and when hemp is grown for its drug it is the custom to eradicate the latter, pruning the remaining female plants so as to make them branch more luxuriantly.

Properties.—Fresh hemp has a characteristic odor, which is much less in the dried tops, which have a feeble bitterish taste.

Description and Physical Properties.—"*Unground Cannabis.*—In separate tops or less agglutinated masses or fragments, consisting of the short stems with their leaf-like bracts and pistillate flowers or more or less developed fruits; color green to dark green or greenish brown; odor agreeable, somewhat heavy and narcotic; taste somewhat acrid and pungent. Leaves digitately compound, usually broken. Leaflets when entire, linear-lanceolate, nearly sessile, margin deeply serrate. Bracts ovate, pubescent, each enclosing 1 or 2 pistillate flowers or more or less developed fruits. Calyx dark green, pubescent and somewhat folded around the ovary. Styles 2, filiform and pubescent. Ovary with a single campylotropous ovule. Stems cylindrical, longitudinally furrowed, light green to light brown, strigose-pubescent.

"*Structure of Stem.*—Cortex composed of collenchyma and, in the larger stems, of numerous strands of more or less lignified bast-fibers; strongly lignified wood with medullary rays 1-cell wide; pith, often hollow; rosette aggregates of calcium oxalate numerous.

"*Powdered Cannabis.*—Dark green; epidermis from lower surface of leaves with sinuate vertical walls and numerous oval stomata, from upper surface with straight walls and no stomata; non-glandular hairs numerous, unicellular, rigid, curved, with a very slender pointed apex and an enlarged base usually containing calcium carbonate masses; glandular hairs of two kinds, one with a short 1-celled stalk, the other with a long multicellular, tongue-shaped stalk, the head being globular and consisting of 8 to 16 cells; fragments of bracts and leaves showing yellowish-brown laticiferous vessels, numerous rosette aggregates of calcium oxalate, 0.005 to 0.030 mm. in diameter, and strands of spiral tracheæ and phloem; fragments of fruits with palisade-like, non-lignified cells with yellowish-brown finely porous walls usually containing air; tissues of embryo and endosperm with numerous oil globules and aleurone grains, the latter from 0.005 to 0.010 mm. in diameter and displaying crystalloids and globoids. Diluted hydrochloric acid added to powdered Cannabis causes effervescence visible under the microscope." *U. S.*

The British Pharmacopœia describes Indian cannabis as follows:

"In compressed, rough, dusky-green masses, consisting of the branched upper part of the stem, bearing leaves and pistillate flowers or fruits, matted together by a resinous secretion. Upper leaves simple, alternate, 1–3 partite; lower leaves opposite and digitate, consisting of five to seven linear-lanceolate leaflets with distantly serrate margins. Fruit one-seeded and supported by an ovate-lanceolate bract. Both leaves and bracts bear external oleo-resin glands and one-celled curved hairs, the bases of which are enlarged and contain crystoliths. Strong, characteristic odor; taste slight. When a mixture of 10 grammes of finely powdered Indian Hemp and 100 millilitres of *alcohol* (90 per cent.) is shaken occasionally during twenty-four hours and then filtered, 20 millilitres of the filtrate, evaporated in a flat-bottomed dish, yield a residue weighing, when dried at 100° C., not less than 0.250 gramme. Ash not more than 15 per cent." *Br.*

For a histological description of the leaf by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1897, 569. The cannabis of the market may consist of fruiting tops and stems and occasionally the staminate tops are admixed with it.

William Beam in Bulletin No. 4 of the chemical Section of the Welcome Tropical Research Laboratories, Khartoum, has discovered a specific color reaction which may be used for the detection of *Cannabis indica* and its preparations. A petroleum ether extract of the suspected material is prepared and evaporated to dryness in a test tube. To this is added a few cc. of a reagent prepared by saturating absolute alcohol with dry hydrogen chloride gas. In the presence of cannabis the liquid assumes a bright cherry red color which is destroyed upon the addition of water or alcohol.

Constituents.—The activity of hemp undoubtedly resides in its resin, but the chemical nature of the active principle is unsettled. By repeated distillation of the same portion of water from relatively large quantities of hemp renewed at each distillation, M. J. Personne obtained a volatile oil, of a stupefying odor, and an action on the system such as to dispose him to think that it was the active principle of the plant. This oil was lighter than water, of a deep amber color, a strong odor of hemp, and composed of two distinct oils, one colorless, with the formula $C_{18}H_{20}$, the other a hydride of the first, $C_{18}H_{22}$, which was solid, and separated from alcohol in plate-like crystals. For the former Personne proposes the name of *cannabene.* It is affirmed that when this is inhaled, or taken into the stomach, a singular excitement is felt throughout the system, followed by a depression, sometimes amounting to syncope, with hallucinations which are generally disagreeable, but an action on the whole slighter and more fugitive than that of the resin. *Cannabindon,* $C_8H_{12}O$, is a dark red syrupy liquid obtained by Kobert (*Chem. Ztg.*, 1894, 741) from *Cannabis indica;* it is soluble in alcohol, ether and oils; it is affirmed to be narcotic in doses of from half a grain to two grains (0.032–0.13 Gm.). As a result of a reinvestigation of charras (churrus) from Indian hemp, Wood, Spivey, and Easterfield (*J. Chem. S.*, vol. lxix, 539) have found the following principles: 1, a terpene, boiling between 150° and 180° C.; 2, a sesquiterpene, boiling at 258° to 259° C.; 3, a crystalline paraffin of probable formula $C_{29}H_{60}$, melting at 63.5° C.; and 4, a red oil, boiling at 265° to 270° C. under a pressure of 20 mm., to which they give the name *cannabinol,* and the formula $C_{18}H_{24}O_2$. This latter constituent they consider the only active ingredient. It is probably the same substance as the dark red syrup of Kobert, mentioned above under the name of cannabindon. The authors found that cannabinol readily underwent superficial oxidation, at the same time losing its toxic activity. It is stated that cannabinol exhibits much more powerful effects when dissolved in a bland oil such as olive oil. Fränkel (*A. E. P. P.*, 1903, p. 266) claims to have isolated the active principle of hashish as a pure and chemically well defined body. It has the formula $C_{21}H_{30}O_2$, and is a phenol-aldehyde. It is of a pale yellow color and of a thick consistency. When heated it becomes quite fluid and distils at 215° C., under a pressure of 0.5 mm. It oxidizes in the air, acquiring a brown tint. It responds to Millon's reaction, and can be acetylized, showing thus its phenol character. Fränkel proposes that the name *cannabinol* be given to it and that the term *pseudo-cannabinol* be given to the substance of Wood, Spivey and Easterfield which Fränkel asserts is inert.

"**Assay.**—Hooper (*P. J.*, 1909, lxxxi, p. 80) describes a method for the chemical standardization of cannabis based upon its iodine value. He finds that the alcoholic extract of old samples has a lower iodine value than that from recent specimens, and there is more or less constancy of relation between the age and the iodine value.

The U. S. Pharmacopœia gives a physiological test for the standardization of *Cannabis indica.* Up to the present no means have been suggested for determining, with even approximate accuracy, the relative potency of different samples of *Cannabis indica,* the physiological test simply demonstrating that the drug possesses a certain indefinite amount of physiological action. The official test is based on the degree of inco-ordination produce in the dog in comparison with that produced by a standard preparation. It is advisable to use the same animal for repeated tests, because the individual susceptibility of the dog varies so greatly, and the experimenter gradually learns the degree of reaction to be expected from a certain dog. It is convenient to employ two dogs (fox terriers usually react well) to one of which will be given the standard and to the other the drug to be tested. Three days later the test should be repeated in reverse order, that is the dog which at the first test received the standard, at the second test should receive the unknown and *vice versa.* A fluidextract of the specimen to be tested is either evaporated into a soft extract and given in the form of a pill or mixed with an inert absorbing powder and enclosed in a capsule; it must not be given hypodermically. The symptoms caused by *Cannabis indica* in the dog recall those of alcoholism in the human being. There is at first a slight loss of control in the hind legs so that the animal staggers as he walks, later the ataxia becomes so marked that the dog is unable to stand up without leaning against some object, and about this time begins to show distinct drowsiness, and may eventually pass into a heavy sleep.

"Use adult dogs which weigh less than 15 kilogrammes and which are susceptible to the action of Cannabis. The dogs must not be fed for twelve hours before being used and observations should be made within one hour after administration The same animal must not be used for testing purposes at shorter intervals than three days. Administer the fluidextract in gelatin capsules by the mouth." *U. S.*

Standard Fluidextract of Cannabis.—In order to obviate the inaccuracies due to variations in susceptibility of the dogs, the present Pharmacopœia directs a comparison to be made with a standard fluidextract of cannabis. This is directed to be prepared as follows:

"Prepare a composite fluidextract, representing at least ten different lots of Cannabis, conforming to the official botanical description, and administer this fluidextract in gelatin capsules to dogs by the mouth. This standard fluidextract must be so adjusted that it will produce incoördination in dogs which have been found to be susceptible to the action of Cannabis when administered in doses of 0.03 cc. for each kilogramme of body weight of dog." *U. S.*

The Bureau of Chemistry, U. S. Department of Agriculture, has indicated its willingness to supply such a standard fluidextract of cannabis for the use of those who desire to make biological assays of this drug.

It has generally been believed that cannabis deteriorates rapidly, but Eckler and Miller (*J. A. Ph. A.,* 1917, vi, p. 872) found that the crude drug showed practically no change after a year's storage but that after two years it had lost about half of its potency; Hamilton (*J. A. Ph. A.,* 1918, vii, p. 117) believes that the loss must be usually much slower because he found a sample fourteen years old to be 70 per cent. of standard, and an extract, which had been constantly used for assay purposes for nine years, has shown no appreciable change.

Uses.—Aside from a slight local irritant effect the action of cannabis seems to be limited almost exclusively to the higher nerve centers. In man this is first manifested by a peculiar delirium which is accompanied with exaltation of the imaginative function and later by a remarkable loss of the sense of time. The delirium is often accompanied with motor weakness and diminished reflexes and generally followed by drowsiness. In the dog the earliest manifestation of the drug's action is a slight degree of restlessness which is soon followed by disturbances of equilibrium and later weakness of the legs and drowsiness.

Cannabis is used in medicine to relieve pain, to encourage sleep, and to soothe restlessness. Its action upon the nerve centers resembles opium, although much less certain, but it does not have the deleterious effect on the secretions. As a somnifacient it is rarely sufficient by itself, but may at times aid the hypnotic effect of other drugs. For its analgesic action it is used especially in pains of neuralgic origin, such as *migraine,* but is occasionally of service in other types. As a general nerve sedative it is useful in *hysteria, mental depression, neurasthenia,* and the like. It has also been used in a number of other conditions, such as *tetanus* and *uterine hemorrhage,* but with less evidence of benefit. One of the great hindrances to the wider use of this drug is its extreme variability. We are inclined to the opinion that one of the important reasons for the lack of confidence in this drug has been insufficiency in dosage. Because of the great variability in the potency of different samples of cannabis it is well nigh impossible to approximate the proper dose of any individual sample except by clinical trial. Because of occasional unpleasant symptoms from unusually potent preparations, physicians have generally been overcautious in the quantities administered. While the inclusion of a physiological assay in the Pharmacopœia has somewhat improved the quality of drug upon the market it must be remembered that the present method of standardization is not quantitatively accurate; all that can be hoped from this assay is the exclusion of inert samples. The only way of determining the dose of an individual preparation is to give it in ascending quantities until some effect is produced. The fluidextract is perhaps as useful a preparation as any; one may start with two or three minims of this three times a day, increasing one minim every dose until some effect is produced. According to C. R. Marshall (*L. L.*, 1897, i, also *J. A. M. A.*, Oct., 1898) the deterioration of cannabis is due to the oxidation of cannabinol, which he has found to act upon dogs and cats as the crude drug.

Dose, of cannabis, one to three grains (0.065–0.2 Gm.).

CANTHARIDINUM. Br.

CANTHARIDIN

"Cantharidin, $C_{10}H_{12}O_4$, may be obtained from various species of Cantharis or of Mylabris." *Br.*

Cantharidine, *Fr. Cod.*; Kantharidin, *G.*; Cantaridina, *Sp.*

Cantharidin is the anhydride (lactone) of *cantharidic acid* and is officially recognized by the Br. Pharm. (1914) and the Swiss and French Pharmacopœias. Preparations made from cantharidin are believed to be more uniform in quality than those made from cantharides because they are made from a definite crystallizable product and it is not always easy to extract all of the cantharidin from powdered Spanish flies by the usual methods, as in making the vinegar, tincture, collodion, cerate or plaster. It has also the theoretical advantage that it can be obtained from various other beetles and hence would still be available in case of a shortage of the true cantharides. (See *Cantharis.*)

E. Dieterich prepares cantharidin by macerating 1000 parts of coarsely powdered cantharides in 1500 parts of acetic ether mixed with 20 parts of sulphuric acid; after adding 40 parts of barium carbonate to neutralize the excess of sulphuric acid, the mixture is exhausted with acetic ether in an extraction apparatus, the liquid is distilled, and the residue, consisting of cantharidin, resin, fat, etc., is set aside for eight days to allow the cantharidin to crystallize; 200 parts of petroleum benzin (sp. gr. 0.740) are then added, gently heated in order to dissolve the fatty matter, the liquid filtered, and the cantharidin washed with petroleum benzin and recrystallized from its solution in 90 per cent. alcohol. If perfectly pure cantharidin is needed, the cantharidin may be dissolved in acetic ether or chloroform and the solution passed through animal charcoal, filtered, and allowed to crystallize. (*J. P. C.*, 1893, 375.)

Properties.—"Colorless glistening crystals, inodorous. Very slightly soluble in *water, petroleum spirit,* or *alcohol* (90 per cent.); more soluble in *chloroform,* in *acetic ether,* and in *acetone;* soluble also in fixed oils. A 0.1 per cent. solution in a fixed oil raises blisters when kept in contact with the skin. Melting point 210° to 212° C. Slowly volatilises at 100° C., more rapidly at higher temperatures. Soluble in *solution of sodium hydroxide,* the solution depositing crystals of Cantharidin when acidified. Gently warmed with *sulphuric acid* it yields a colorless solution, from which it is separated unchanged when freely diluted with *water.*" *Br.*

Cantharidin itself has been found to combine like an acid with salifiable and earthy bases, forming soluble compounds with potassium, sodium, and lithium hydroxides, salts of very sparing solubility with baryta, strontia, and lime, and with magnesia a salt which, though feebly soluble in water (100 parts of water dissolving only 0.24 of the salt) (see *P. J.*, March 13, 1880), is much more largely dissolved in cold than hot water, and in cold than in hot alcohol. The potassium salt crystallizes with 3 molecules of water, and is soluble in 25 parts of water. On the addition of strong acids to this solution, cantharidic acid is not precipitated, as might be expected, but the lactone cantharidin. This potassium salt has been recommended by Liebreich for subcutaneous injections. The most satisfactory test of cantharidin is its vesicating property. Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts act as effectually in exciting vesication as do the flies themselves, while the residue is in each case inert. Cantharidin probably exists in the insect so combined as to be rendered soluble in water and cold alcohol; if as stated by E. Dieterich (1883), formic acid is present in the Spanish fly, it is possible that the solution of the cantharidin is due to its presence. He also showed that cantharidin was not volatilized with the vapor of benzin, a fact which may prove useful in preparing blistering plasters coated with a benzin solution of cantharidin. (*Ph. Centralh.*, 1901, 464.) H. G. Greenish calls attention to the fact that much loss of cantharidin takes place in making the various pharmaceutical preparations, through insufficient exhaustion by the use of the ordinary solvents. He obtained 0.822 per cent. of cantharidin from exhausted residues. Homolka records (*B. Chem. G.*, 1886, xix, 1082) the results of an investigation of the chemical decompositions of cantharidin.

Uses.—Cantharidin is used for the same purposes as Cantharides (see below). Liebreich strongly recommended hypodermic injections of cantharidin in the treatment of *phthisis,* but general clinical experience has not confirmed the value of the remedy. *Liebreich's cantharidal solution* was made by heating 20 cc. of water with 0.2 Gm. of cantharidin and 0.4 Gm. of potassium hydroxide until solution was obtained, then adding enough water to make 1000 cc. Of this solution he injected from 0.5 to 1.0 cc. at a dose.

Dose, of cantharidin, is from one two-hundred-and-fortieth to one one-hundred-and-twentieth grain (0.00025–0.0005 Gm.).

CANTHARIS. U. S.

CANTHARIDES Canthar. [Spanish Flies, Russian Flies]

"Cantharides consists of dried insects [*Cantharis vesicatoria* (Linné) De Geer (Order *Coleoptera*)]. Cantharides yields not less than 0.6 per cent. of cantharidin and not more than 10 per cent. moisture." *U. S.*

Blistering Flies; Muscæ Hispanicæ; Cantharide, *Fr.;* Cantharides, *P. G.;* Spanische Fliegen, Kantharide, Canthardén, *G.;* Cantaride, Cantarella, Mosca di Spagna, *It.;* Cantarida, *Sp.*

Cantharis is recognized in all of the European Pharmacopœias, but has been dropped by the British authority, being replaced by cantharidin.

The term *Cantharis* was employed by the ancient Greek writers to designate many coleopterous insects or beetles. Linnæus gave the title to a genus not including the official blistering insect, and placed this in the genus *Meloë,* which, however, has been since divided into several genera. Geoffrey made the Spanish fly (beetle) the prototype of a new genus, *Cantharis,* substituting *Cincindela* as the title of the Linnæan genus. Fabricius altered the arrangement of Geoffrey, and substituted *Lytta* for *Cantharis* as the generic name. The former was adopted by the London College, and at one time was in extensive use; but, the latter, having been restored by Latreille, is now recognized in the British and U. S. Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe, corresponding very nearly with the Linnæan genus *Meloë,* and distinguished by the title *Cantharidæ.* This tribe he divided into eleven genera, among which is *Cantharis.*

Cantharis vesicatoria is from 15 to 25 mm. long, and of a shining, golden-green color. The head is large and heart-shaped, bearing a pair of stout mandibles and filiform antennæ; the thorax short and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. (Snyder, *A. J. P.,* 1908, p. 545.) When alive, the Spanish flies have a strong, penetrating, fetid odor, compared to that of mice, by which swarms of them may be detected at a considerable distance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. They are most abundant in Spain, Italy, and Southern France, but are found also in all the temperate parts of Europe and in Western Asia. According to the researches of Lichtenstein, the eggs are laid by the female in the latter part of June in small cylindrical holes made in the ground. A week later the larvæ hatch out. They are a millimeter long, with two long caudal threads, and of a brown color. After many efforts, Lichtenstein succeeded in getting them to feed on the honey contained in the stomach of bees. In a few days they changed into milk-white larvæ, and about a month after this buried themselves in the ground, to assume the chrysalis stage and to hatch out the following spring as perfected beetles. In the wild state the larvæ are said to crawl up flowers and attach themselves to bees or other hymenopterous insects; carried by the bee to the hive, the larvæ feed upon the young bees and the honey and bee-bread stored up for use. The beetles usually make their appearance in swarms upon the trees in May and June, when they are collected.

The time preferred for this purpose is in the morning, at sunrise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks, and their hands with gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the fumes of ammonia, vinegar, chloroform, burning sulphur or carbon bisulphide, and, having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. When perfectly dry, they are introduced into casks or boxes lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture.

Cantharides come chiefly from Spain, Southern Russia and Hungary, and other parts of the Mediterranean as Sicily, Poland, and Roumania. The Russian flies are most esteemed. They may be distinguished by their greater size, and their color approaching to that of copper.

In the United States are several species of Cantharis, which have been employed as substitutes for *C. vesicatoria* and found equally efficient; but none of them are now recognized by the U. S. Pharmacopœia, even *C. vittata,* which was at one time official, having been discarded. For description of unofficial blistering beetles, see *U. S. D.,* 19th edition, p. 284. Various other allied insects have been used at one time or another as a substitute for the Spanish beetle.

Cantharis vittata Latreille or "potato fly" was recognized by the U. S. P., 1850. It is rather smaller than *C. vesicatoria,* which it resembles in shape. Its length is about six lines. The head is light red, with dark spots upon the top; the feelers are black; the elytra or wing-cases are black, with a yellow longitudinal stripe in the center, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same color, are covered with a cinerous down. It inhabits chiefly the potato vine, and appears about the end of July or beginning of August, in some seasons very abundantly. Fahnestock procured 1⅓ per cent. of the cantharidin from this beetle. (*A. J. P.*, xxviii, 195; li, 298.) This insect must not be confounded with the "potato bug," the *Colorado potato beetle* (*Doryphora decemlineata*), which has proved so destructive to potato plants, and which, according to the researches of L. Dembinski (*A. J. P.*, 1877, p. 550) contains no cantharidin.

Mylabris cichorii is thought to be one of the insects described by Pliny and Dioscorides under the name of cantharides, and is to this day employed in Italy, Greece, the Levant, Egypt, and China. W. R. Warner found 500 parts of *M. cichorii* to yield 2.13 parts of cantharidin. (*A. J. P.*, xxviii, 195.) The *M. cichorii* was formerly imported to some extent under the name of *Chinese blistering fly*. It is black, with the powder blackish gray and free from shining particles; it yielded to Fahnestock 1.25 per cent. of cantharidin. (*A. J. P.*, 1879.)

The Br. Add. under the name of *Mylabris* formerly recognized not only the dried beetle, *Mylabris phalerata* Pallas (*M. Sidae* Fabr.) but also allowed the use in the Colonies of other species of the genus, provided that they yield a similar proportion of cantharidin. Mylabris was characterized in the Br. Add. as "usually an inch (twenty-five millimetres) or rather more long, and three-eighths of an inch (nine millimetres) broad; with two long elytra, each three times as long as broad, black with two broad wavy transverse orange-colored bands and a large orange-colored spot at the base of each; one pair of brown membranous wings."

Among other insects that have occasionally found their way into commerce may be mentioned: *Cantharis quadrimaculatus* (*Mexican Cantharides*), *Mylabris lunata, M. bifasciata* (from South Africa), *Epicauta gorhami* (from Japan), *Lytta aspersa* (from Argentina), etc.

Description and Physical Properties.—"*Unground Cantharides.*—From 15 to 25 mm. in length, 5 to 8 mm. in breadth, oblong, somewhat compressed above; of a brilliant green or bluish-green, metallic luster, changing in different parts, especially beneath, to a golden-green; head triangular, separated into two lateral lobes by a faint median line; mandibles stout and partly concealed; antennæ filiform, of eleven conical joints, the upper ones being black; eyes comparatively small; prothorax angulate; legs with five tarsal joints; wings membranous and brownish; elytra or wing sheaths each with two parallel lines and finely wrinkled; odor strong, disagreeable; taste slight, afterwards acrid. Cantharides with an ammoniacal odor must not be used.

"*Powdered Cantharides.*—Grayish-brown, with shining green particles and a number of long, pointed, spicules 0.500 mm. in length and 0.020 mm. in width.

"**Assay.**—Place 15 Gm. of Cantharides, in moderately coarse powder, in a stout bottle of not less than 250 cc. capacity, add 150 cc. of a mixture of benzene, two volumes, and purified petroleum benzin, one volume, and then add 2 cc. of hydrochloric acid. Stopper the bottle tightly, shake it well, and allow it to stand about ten hours. Now gradually warm the bottle and its contents to about 40° C., and maintain it at approximately that temperature with frequent shaking during three hours, avoiding evaporation. If necessary add additional solvent to replace any lost by evaporation. Cool the mixture, decant or filter off 100 cc. of the clear solution, and evaporate this rapidly in a tared beaker or wide-necked flask to a volume of about 5 cc. Add 5 cc. of chloroform to the residue and set it aside in a moderately warm place. When the solvent has all evaporated, add to the crystals 10 cc. of a mixture of equal volumes of dehydrated alcohol and purified petroleum benzin, which has previously been saturated with pure cantharidin, allow the mixture to stand during fifteen minutes, and then decant the liquid through a pledget of purified cotton. Wash the crystals with successive portions of a saturated solution of cantharidin, similar to that directed above, until free from fat and coloring matter, and pass the washings through the same pledget of purified cotton. Then wash the cotton with a very small quantity of warm chloroform to dissolve any adhering crystals, collect the chloroform in the tared flask or beaker containing the washed crystals, evaporate the solvent with the aid of a blast of air, dry the crystals at 60° C. for one half hour, and weigh. The resulting weight will be the amount of cantharidin obtained from 10 Gm. of Cantharides." *U. S.*

For other methods of assay see *U. S. D.*, 20th ed., p. 281; also *P. J.*, 1903, p. 558 and p. 783.

Dried Spanish flies preserve the form and color, and, to a certain extent, the disagreeable odor, of the living insect. They have an acrid, burning, and urinous taste. If kept perfectly dry, in well-stoppered glass bottles, they retain their activity for a great length of time, but exposed to a damp air they quickly undergo putrefaction, and this change takes place more speedily in the powder. Hence the insects should either be kept whole, and powdered as they are wanted for use, or, if kept in powder, should be well dried immediately after pulverization, and preserved in air tight vessels. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. Davis (*Proc. Mich. Ph. Ass.*, 1910, p. 62) reports that when cantharis is subjected to a microscopical examination the presence of other kinds of beetles and insects may be detected. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the hard exterior parts are not affected. An idea was at one time prevalent that the vesicating property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. Farines, an apothecary of Perpignan, has satisfactorily shown that, though the hard parts left by these mites possess some vesicating power, the sound flies are much stronger. Among the best means of preserving them, whether whole or in powder, is the application of the process of Apert, which consists in exposing them for half an hour, confined in glass bottles, to the heat of boiling water, which destroys the eggs of the insect, without impairing the virtues of the flies. (*J. P. C.*, xxii, 246.) Of course, the access of water to the flies should be carefully avoided. The use of chloroform or carbon tetrachloride are among the simplest, safest and best preservatives to prevent the development of insects in drugs. Cantharides will bear a very considerable heat without losing the brilliant color of their elytra; nor is this color extracted by water, alcohol, ether, or the oils, so that the powder might be deprived of all its active principle and yet retain the exterior characters unaltered. The wing-cases resist putrefaction for a long time, and the shining particles have been detected in the human stomach, months after interment.

The activity of cantharides is due to the anhydride cantharidin which was discovered by Robiquet in 1810. (See previous article.) There is present also about 12 per cent. of a fixed oil and, according to Orfila, a volatile principle, upon which the fetid odor of the fly depends. It is separable by distillation with water. The green color is probably not due to chlorophyll as was formerly believed, nor to any pigment at all, but is produced by light interference of their translucent films of tissue. Cantharidin exists in commercial cantharides to the extent of from 0.6 to 0.9 per cent. (See also *Ph. Centralh.*, 1901, 674.)

Adulterations.—These are not common. Occasionally other insects, or even beads, are added, purposely or through carelessness. These may be readily distinguished by their appearance. Flies exhausted of their cantharidin are sometimes substituted for the genuine drug. They are worthless, and are to be distinguished by their lack of substance and their yielding a nearly colorless ethereal tincture.

The percentage of cantharidin found in cantharides furnishes the best test of their virtues.

Uses.—Internally administered, cantharides are a powerful irritant, with a peculiar direction to the urinary and genital organs. Genito-urinary irritation is ordinarily the first symptom produced by small doses of cantharides, and, if the dose has been large enough, it may amount to violent strangury, attended with excruciating pain, and the discharge of bloody urine.

Lipsitz and Cross (*A. I. M.*, 1917, xx, 913) have found that cantharides cause a marked increase in the number of red blood cells, but Morgulis and Muirhead (*A. I. M.*, 1919, xxiii, 190) believe that this is only an apparent increase due to the loss of water from the system.

Cantharides or some similar vesicating insect appears to have been used as far back as the time of Hippocrates in the treatment of dropsy and amenorrhea. While there is no doubt that by its local irritant effect cantharides will increase the quantity of urine, because of the danger of undue irritation of the kidney, it has been almost completely abandoned in favor of less harmful diuretics.

Because of the priapism seen in cantharides poisoning the drug is often used in *sexual impotence* but it is capable of such serious injury that its employment is not often advisable. As an internal remedy, cantharides is of little practical value.

Externally applied, cantharides excite inflammation in the skin, which terminates in a copious secretion of serum under the cuticle. It may be employed either as a rubefacient, or to blister. In the former capacity it has no peculiar value, but as an epispastic it is preferred to all other substances. When blisters are allowed to stay on only long enough to irritate the skin, but not to blister, they are known as *flying blisters*. Used in this way, they are sometimes of service in *neuralgias*, applied directly over the seat of pain. The chief use of cantharides is to produce true blisters for the relief of various internal inflammations as *neuritis, peritonitis, pneumonia, pleurisy*, etc.

It is possible for enough cantharidin to be absorbed by the raw surface of a blister to cause marked irritation of the genito-urinary tract. In order to avoid such genito-urinary irritation, and also as much as possible the pain at the seat of application, the blister should be left on only until it distinctly reddens the skin, when a flaxseed poultice may be applied, and in the course of two or three hours the blister is formed. The time necessary for such reddening of the skin is usually from four to six hours, if the cantharides be active. (See *Ceratum Cantharidis.*)

Toxic doses of Spanish fly produce obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, excessive salivation with a fetid breath, hurried respiration, a hard and frequent pulse, burning thirst, exceeding difficulty of deglutition, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Orfila has known twenty-four grains of the powder to prove fatal. Dissection reveals severe and acute inflammatory changes in the kidney, the intestines and sometimes the spleen (see *J. A.*

M. A., 1921, lxxvi, p. 50). According to Poumet, if the intestines be inflated, dried, cut into pieces, and examined in the sun between two pieces of glass, they will exhibit small shining yellow or green points, strongly contrasting with the matter around them. (*J. P. C.,* 3e sér., iii, 167.)

The poisonous effects are to be counteracted by the use of emetics, cathartics, and opiates by the stomach and rectum. From the experiments of Schroff it seems that oils somewhat accelerate the poisonous action, probably by dissolving the cantharidin. (See *A. J. P.,* xxviii, 365.) The use of animal charcoal as an antidote was suggested by Thouery, a French apothecary, in 1858, but as far as we know has not been tried in human poisoning.

The dose of cantharides may be stated as one-half to one grain (0.032–0.065 Gm.) but it is rarely prescribed.

CAPSICUM. U. S. (Br.)

CAPISCUM Capsic. [Cayenne Pepper, African Chillies]

"Capsicum is the dried ripe fruit of *Capsicum frutescens* Linné (Fam. *Solanaceæ*), grown in Africa. Capsicum contains not more than 3 per cent. of its stems, calyxes, and not more than 1 per cent. of other foreign organic matter, yields not less than 12 per cent. of non-volatile ether-extractive, and not more than 1.25 per cent. of acid-insoluble ash." *U. S.* "Capsicum is the dried ripe fruit of Capsicum minimum, *Roxb.*" *Br.*

Capsici Fructus, *Br.;* Piper Hispanicum; Capsicum Fruit, African or Pod Pepper, Red Pepper, Chillies, Bird Pepper, Spur Pepper; Fructus Capsici, *P. G.;* Spanischer Pfeffer, Schlotenpfeffer, *G.;* Piment de Cayenne, Piment des Jardins, Poivre d Espagne, Poivre de Guinée, Poivre d'Inde, Poivre de Cayenne, Piment rouge, Capcique, *Fr.;* Peperone, *It.;* Pimiento, Chile, Aji, *Sp.*

Owing probably to its widespread cultivation, the genus *Capsicum* contains a large number of plant forms whose specific relations afford a very difficult problem to the systematic botanist. The probability is that the entire genus was originally confined to the American tropics, although it has been cultivated since the time of Columbus in the temperate and tropical zones of almost the whole world. Its first appearance in literature seems to be in an epistle by Peter Martyn, dated September, 1493, speaking of its having been brought by Columbus. Neither in ancient Sanscrit, Chinese, Greek, Latin, or Hebrew is there a name for it. In 1887 Asa Gray expressed his belief that there are only two species in the genus, although in the last previous revision of the genus, in 1852, Dunal had recorded fifty species. After a very thorough and careful study of the subject, including the cultivation of every procurable variety and species for four years in the Missouri Botanical Garden, H. C. Irish reached the conclusion that the dictum of Gray was correct, and that there are really only two species of the genus, one of which is herbaceous and annual or biennial, the other shrubby and perennial, a conclusion which seems to be accepted.

The first of these species is the one most extensively cultivated in Europe and in this country; it is the *C. annuum* L. The second is in its varieties very largely grown in the tropical and subtropical latitudes, its fruit not ripening at all or only to a slight degree in the temperate zone. It is the species which was described under the name of *C. frutescens,* by Linnæus, in 1737. By Irish it is divided into two varieties—*C. frutescens* proper, which is characterized by its fruit being oblong, acuminate, and usually embraced by the calyx, and *C. frutescens baccatum,* which is characterized by its ovate or subround fruit, usually seated on the calyx. This variety is the *C. baccatum* of Linnæus, 1767. In the first of these varieties are comprised the *C. fastigiatum* of Blume and the *C. minimum* of Miller and of Roxburgh, which yield most of the Cayenne pepper produced in the tropics, although, especially in the West Indies and South America, *C. baccatum* is largely cultivated.

The British Pharmacopœia seems to be in error in ascribing the original description of the *Capsicum minimum* to Roxburgh, since his *Flora Indica* did not appear until 1832, whereas the species was described by Miller, in the *Garden Dictionary,* in 1771.

Capsicum frutescens, the shrubby capsicum, is cultivated in the United States, Mexico, India, Japan and British East Africa. The fruits are collected when fully mature, deprived of their calyces, and carefully dried. Most of the drug used in this country comes from Zanzibar, Mombaza, Nyasal or Sierra Leone.

The following are the characteristics of the plant as given by Irish: "Plants shrubby, perennial, two and a half to six feet high. Branches angular, often channelled, puberulent or pubescent, especially on the younger portions; usually greatly enlarged and slightly purple at the nodes, green or sometimes purplish striate. Leaves broadly ovate, acuminate, 7.5 to 15 cm. long, usually puffed or wrinkled, more or less pubescent, especially around the veins. Petioles medium, usually subciliate; peduncles slender, 2.5 to 5 cm. long, often in pairs, usually longer than the fruit. Calyx usually cup-shaped, embracing base of the fruit; teeth short, corolla white or greenish white, spreading 10 to 20 mm. long, often with ocherous markings in the throat. Fruit red, ovate, obtuse or oblong acuminate, 20 to 30 mm. long and 6 to 18 mm. in diameter."

Capsicum annuum is largely cultivated both in the United States and in Europe, flowering in the early or middle summer, and ripening its fruit in the early autumn. There are numerous varieties of it differing in the shape of their fruit. That which is chiefly cultivated in the United States for market, to be used in the green state in pickling, or cooked for the table, is a large irregularly ovate or conical berry depressed or horned at the extremity, and when ripe varying in color from yellowish to scarlet. A variety with a long, conical, pointed and recurved fruit, which is usually not thicker than the finger, is said to be especially used in the making of red pepper. In another variety the berries are not more than an inch in diameter, spherical and slightly compressed.

When ground into powder the fruit of the *Capsicum annuum* constitutes *paprika,* or as it is sometimes called, *sweet pepper;* it has scarcely more than one-sixth the pungency of real cayenne pepper, so that the addition of it to powdered chillies may be considered an adulteration.

Paprika or *Hungarian pepper* is recognized by the German Pharmacopœia. It is usually imported into the United States in a ground condition, three grades being recognized. 1. *Rosen-paprika* or *Rozsapaprika,* the best grade, possesses a beautiful red color and has a savory taste. It is prepared from the selected pericarp and seeds which are carefully washed before being ground, the stems and placentæ being removed. 2. *Königs-paprika* or *Kiralypaprika* is prepared by grinding the entire pods, including not only the seed but the stems. 3. *Mercantil-paprika* is prepared from the spotted pods, remaining from the selection for the finer grades, and from the pods containing flaws and also contains the stems, seeds and other parts. The last grade has a pale yellow color and is much more pungent. (Tolman and Mitchell, *Bull. No. 163, Bureau of Chemistry, U. S. Dept. of Agriculture.*) The cayenne pepper of the grocery stores is often a mixture of paprika and true pepper. It is possible to distinguish the presence of paprika in powdered capsicum by the microscopic differences of the epidermal cells of the pericarp as seen in a surface view; those of paprika are polygonal and irregularly arranged whereas those of true capsicum are rectangular and arranged in parallel rows.

T. Edward Wallis believes that the different cayenne peppers can be distinguished from one another when powdered by the character of their epidermis and the tissue immediately below it, and gives the following tabulated summary of the differences. (*P. J.*, July, 1902.)

	C. minimum.	*C. annuum.*	*Japanese Chillies.*
Epidermis.	Thick and straight-walled rectangular cells with few pits; often arranged in groups of five to seven in a row and with a uniformly striated cuticle. Size of cells, 25 mkm. to 60 mkm. in either direction.	Irregular polygonal cells with evenly thickened walls, traversed by numerous well-marked, simple pits. The cuticle shows striated ridges. Size of cells, 60 mkm. to 100 mkm. long, and 25 mkm. to 50 mkm. wide.	Cells with strongly thickened walls and a radiated lumen. The pits only rarely penetrate the whole thickness of the wall. No visible striation. Size of cells, 30 mkm. to 80 mkm. long, and 15 mkm. to 45 mkm. wide.
Hypodermis.	Delicate thin-walled cellulose cells.	Several layers of cuticularized collenchymatous cells, having a rounded outline and very few pits.	A single layer of regular polygonal cells with cuticularized, fairly thick walls, traversed with numerous pits, which give them a beaded appearance.

The varieties of cayenne peppers are numerous as they occur in the American market—the pods of the *East African pepper* are about 12 mm. in length, flattened, almost cylindrical, although showing distinctly the conical form; the pods of the *Madagascar pepper* reach the length of 6 to 7 cm. and a breadth of about 20 mm.; those of the *Bombay* or *cherry pepper* are very dark in color, 3.5 to 5 cm. in length, and 12 mm. or more in breadth at the base. They are strictly conical and less likely to be flat than those of the other varieties. *Zanzibar pepper* is smaller than the *East African pepper* but otherwise similar to it. *Japanese capsicum,* whose botanical source is not positively known, occurs in the market in two forms, one in which the pods are large, reaching the length of about 6 cm.; the other in which the small pods are not 2.5 cm. in length. The larger pods are scarcely to be distinguished from *Madras chillies;* the smaller resemble, but are nearly twice the size of, the East African pepper. The color of the pods varies from light yellowish-brown to deep red.

Description and Physical Properties.—"*Unground Capsicum.*—Oblong conical, usually laterally compressed, from 10 to 25 mm. in length, from 4 to 8 mm. in diameter, 2- or 3-locular, the dissepiments united to a short conical placenta at the base of the fruit; pericarp orange to dark brownish-red, glabrous, shriveled, dull, thin, membranous; inner surface longitudinally striate, with 2 or 3 distinct longitudinal ridges; seeds, yellowish or brownish, 6 to 21, circular or irregular, flattened, from 2 to 4 mm. in diameter, with a thickened edge and prominent pointed micropyle; odor characteristic, sternutatory; taste intensely pungent. Calyx light greenish-brown, inconspicuous, inferior, 5-toothed, usually attached to a long, straight peduncle.

"*Structure.*—Outer epidermis of mostly quadrangular cells from 0.020 to 0.080 mm. in length, from 0.020 to 0.045 mm. in width and from 0.015 to 0.020 mm. deep, arranged in irregular rows, with thickened and cutinized outer and radial walls, the surface of the cuticle finely striated, the radial walls somewhat wavy and very slightly beaded; mesocarp of thin-walled parenchyma containing reddish-yellow oil globules; endocarp of elongated cells, some of them very thin-walled, others in large oval areas, with thickened, beaded lignified walls. Epidermal cells of seed irregular in outline up to 0.250 mm. in length, with very wavy, contorted, lignified walls, the cells from the edge of the seed much thicker-walled than those from the flat surface of the seed. Embryo curved and embedded in the endosperm, the latter consisting of small, thin-walled parenchyma, containing small aleurone grains and fixed oil.

"*Powdered Capsicum.*—Yellowish or reddish-brown; consists of thin-walled parenchyma containing oil globules, epidermal cells of pericarp and seed-coat and stone cells of endocarp.

"Fragments of pericarp with outer epidermis consisting of irregular cells up to 0.100 mm. in length, not arranged in regular rows and with strongly beaded radial walls, and with a hypodermis of angular cells with thickened, beaded walls, indicate the presence of Japanese or East Indian Capsicum. Capsicum should meet the requirements of the following test: Mix well 1 Gm. of powdered Capsicum in 50 cc. of alcohol in a stoppered flask and macerate for twenty-four hours. Dilute 0.1 cc. of the clear, supernatant liquid with 140 cc. of distilled water containing 10 per cent. of sucrose: 5 cc. of this dilution swallowed at once will produce a distinct sensation of the pungency of Capsicum in he throat of at least two out of three individuals.

"**Assay.**—For non-volatile ether-soluble extractive, proceed as directed on page 1552." *U. S.*

The Br. Pharm. gives the characteristics of the fruit of *C. minimum* as "Dull orange-red, oblong-conical, obtuse, two-celled fruits, from about twelve to twenty millimetres in length and about six millimetres in diameter; sometimes attached to a five-toothed inferior calyx, and long, straight, slender peduncle. Pericarp somewhat shrivelled, glabrous, translucent and leathery, containing from ten to twenty small flat seeds, either loose or attached to a thin reddish dissepiment. The cells of the outer epidermis of the pericarp have moderately thick walls, are often arranged in rows of five to seven, and exhibit a cuticle uniformly striated (distinction from the fruits of other species of Capsicum). Characteristic odor; taste intensely pungent. Ash not more than 7 per cent." *Br.*

A detailed description of African chillies can be found in Youngken's *Pharmacognosy.*

Gathercoal and Terry (*J. A. Ph. A.*, 1921, x, 423) recommend an organoleptic test; as a standard for pungency they suggest either capsaicin or piperine. The U. S. now includes a test of this type.

The difficulty of distinguishing the source of powdered capsicum is increased by the fact that the red color fades upon exposure to light, and that the powdered African pepper, though very powerful, is a light brownish-yellow. The value of any specimen may be, however, fairly estimated by the intensity of its odor, which is peculiar, somewhat aromatic, and extremely irritant, and by its acrid, burning taste.

Constituents.—The principle described by Braconnot, and named *capsicin,* is a mixed substance, consisting of resinous and fatty matters. In 1876, Thresh isolated a well defined active principle, *capsaicin,* from the extract which he obtained by exhausting Cayenne pepper with petroleum. From the red liquor dilute caustic alkali removes capsaicin, which is to be precipitated in minute crystals by passing carbon dioxide through the alkaline solution. The crystals may be purified by recrystallizing them from either alcohol, ether, petroleum benzin, glacial acetic acid, or hot carbon disulphide; in petroleum, capsaicin is but sparingly soluble, yet it is dissolved abundantly on the addition of fatty oil. The crystals of capsaicin are colorless, and have the formula $C_{18}H_{27}O_3N$, but is not alkaloidal. E. K. Nelson states that capsaicin is a condensation product of vanilylamine (3-hydroxy-4-methoxy-benzylamine) with decylenic acid. They melt at 59° C., and begin to volatilize at 115° C., but decomposition can be avoided only with great care. The vapors of capsaicin are of the most dreadful acridity, and even the ordinary manipulation of that substance requires much precaution. Moerbitz (1898) isolated a pungent principle having a bitter taste, which he states is neither capsicin nor capsicol, and names *capsicutin.* He gives it the formula $C_{35}H_{54}O_4N_3$, and states that it is neither an alkaloid nor glucoside; it does not have acid properties.

Red lead oxide has been added to the powdered capsicin sold in Europe; it may be detected by digestion in diluted nitric acid, and precipitating the lead by sodium sulphate. Capsicum is said to be sometimes adulterated with colored sawdust, which may be recognized by the microscope. It is often adulterated with inert vegetable substances. The British Pharmacopœia requires that capsicum should yield on incineration not more than 6 per cent. of ash; this test would detect the presence of most adulterants. It is frequently attacked by insects.

Uses.—Capsicum is a very powerful local stimulant, producing, when swallowed, a sense of heat in the stomach, and a general glow over the body without any narcotic effect. It is much employed as a condiment, especially in hot climates, and is useful in cases of *atony of the stomach* or *intestines.* It is strongly contraindicated by the existence of gastric catarrh of the ordinary type, but in the chronically inflamed stomachs of persons of intemperate habits it frequently appears to do good. It is also of value in certain cases of serous *diarrhea,* not dependent on true inflammation of the intestines.

Applied externally, Cayenne pepper is a powerful rubefacient, which has the advantage of acting speedily without the danger of producing vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a liniment. It may be used in strengths of from 10 to 20 per cent. mixed either with alcohol or cotton-seed oil. The powder or tincture brought into contact with a *relaxed uvula* often acts very beneficially. The tincture has also been used advantageously in *chilblain*. The fluidextract and the oleoresin (*Oleoresina Capsici, U. S.*) are powerfully rubefacient. A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or by adding half a fluidounce of the tinctura to eight fluidounces of rose water.

Dose, of the powder, from one to five grains (0.06–0.3 Gm.), which is most conveniently given in the form of pill.

CARAMEL. N. F.

CARAMEL Caram. [Saccharum Ustum, Burnt Sugar Coloring]

"A concentrated aqueous solution of the product obtained by heating sugar or glucose until the sweet taste is destroyed and a uniform dark brown mass results, a small amount of alkali or alkali carbonate being added while heating." *N. F.*

Gebrannte Zucker, *G.*

When sucrose is heated above its melting point but short of a charring temperature it develops a deep brown color, and is finally transformed to a brown, sticky mass which is called caramel. Glucose, when treated similarly, yields a like product. Caramel is undoubtedly a carbohydrate of high molecular weight and condensation or a polymerization product of the monosaccharids or disaccharids. Its formula has been suggested as $C_{125}H_{188}O_{80}$. It is usually found in commerce as a thick liquid which is a concentrated solution of the solid mass which results when anhydrous sugar is used. Solid caramel is an amorphous, reddish-brown, brittle mass, quite porous and highly deliquescent. Caramel made from cane sugar is more soluble in hydroalcoholic liquids than that made from glucose, on account of the dextrins present in glucose, which yield derivatives not readily soluble in alcohol.

Description and Physical Properties.—"Caramel is a thick dark brown liquid having the characteristic odor of burnt sugar and a pleasant, bitter taste. Caramel mixes clear with water in all proportions, 1 part dissolved in 1000 parts of distilled water yielding a clear solution having a distinct sepia tint. The color of this solution is not changed and no precipitate is formed after exposing to sunlight for six hours. It is soluble in diluted alcohol, but is precipitated when the alcoholic content of the solution is increased to 80 per cent. or more by volume. It is insoluble in ether, chloroform, acetone, benzene or petroleum benzin or oil of turpentine. Specific gravity not less than 1.35 at 25° C. Spread a thin layer of Caramel on a glass plate. It appears homogeneous, reddish brown and transparent.

"No precipitate is produced in 20 cc. of an aqueous solution of Caramel (1 in 20) on the addition of 0.5 cc. of phosphoric acid. Caramel swells when incinerated and forms a coke-like charcoal, which burns off only after prolonged heating at a high temperature, and yields not more than 8 per cent. of ash." *N. F.*

Beringer (*A. J. P.*, lxxxiv, p. 160) proposes, for the sake of uniformity (which is difficult to obtain in commercial caramels), a purified caramel made as follows: Caramel, 1000 Gm.; Alcohol, 3500 cc.; Monohydrated Sodium Carbonate, 4 Gm.; Water, *a sufficient quantity.* Weigh the caramel into a capacious bottle or flask, add 250 cc. of boiling water and thoroughly mix. Add gradually 3000 cc. of alcohol, shaking after each addition. Set aside for six hours. Decant the alcoholic solution and wash the precipitate on a filter with two portions of 250 cc. each of alcohol. Allow the precipitate to drain free from alcohol, dissolve it in 1500 cc. of warm water, add the monohydrated sodium carbonate, filter the solution, evaporate it to a thick syrup and spread it upon glass plates to dry. Remove from the plates when dry and place in a desiccator over sulphuric acid until it ceases to lose weight. This process yields about 40 per cent. of purified caramel which has a high coloring power and great uniformity. George A. Menge proposes to make a standard solution of caramel for adjusting the tinctorial power of caramel as follows: Make a sulphuric acid solution by adding 1 cc. of pure concentrated sulphuric acid (sp. gr. 1.84) to 12 cc. of water. Take 0.5 Gm. of sugar in a test-tube, add 5 cc. of the acid solution described and heat the mixture in a bath of boiling water, with the mixture continuously submerged and with constant agitation, for exactly five minutes. Immediately add a little cold water and then 35 cc. of the U. S. P. test solution of potassium hydroxide; finally dilute to 100 cc. The whole procedure takes about fifteen minutes. (*A. J. P.*, 1911, 113.)

A very satisfactory test for the identification of caramel in flavoring extracts and other liquids where it may be used as a color, has been proposed by G. H. P. Lichthardt. (*J. I. and E. C.*, xi, p. 389.) The following solution is required: Tannic acid, 1 Gm.; Sulphuric Acid (sp. gr. 1.84), 0.75 Gm.; Distilled Water, q. s. to make 50 cc. Dissolve the tannic acid in about 30 cc. of water, add the sulphuric acid (the precipitate at first forming will redissolve) and then the remainder of the water. Let it stand twenty-four hours and filter. Add 5 cc. of this solution to 5 cc. of the liquid to be tested, heat gently until the precipitate at first formed is nearly all dissolved, then set aside for twelve hours or over night; a brown precipitate adhering closely to the bottom of the tube will be found when caramel is present. A flocculent, non-adhering precipitate is to be ignored. With highly alcoholic liquids the alcohol should be removed by evaporation and the volume restored by the addition of water before applying the test.

Caramel contains besides some undecomposed sugar, an odorous principle (furfural), a coloring matter, and a white hygroscopic substance called *caramelan.*

Caramelan, $C_{12}H_{18}O_9$, has been exhaustively investigated by Cunningham and Doree (*P. J.,* 1117, xcviii, 408.) It is described as a buff-colored powder melting at 136° C. Various derivatives have been prepared and it is stated to be an intermediate product between cellulose and humus.

F. Ehrlich (*Bull. Chim. Soc.,* 1909, 140) states that the coloring principle in cane sugar caramel is an amorphous, tasteless compound, not precipitated by lead acetate, and having the chemical formula $C_{12}H_{22}O_{11} + 2H_2O$, and to which he gives the name *saccharane.* The yield from sucrose is about 20 per cent. Dextrose, fructose and starch produce no saccharane.

Pure grape sugar and pure cane sugar caramel, for experimental purposes, have been prepared by G. D. Beal and H. F. Greler, according to methods outlined in *J. A. P. A.,* 1914, p. 495. The resulting products are in the form of scales made by evaporating the solutions on glass plates. Sucrose produces a darker caramel than dextrose, when working under exactly the same conditions, in the ratio of about 10 to 1.

Uses.—Caramel is used in medicine only as a coloring agent.

CARBO.

CARBON

$C = 12.$

Carbone, *Fr.;* Kohlenstoff, *G.;* Carbone, *It.;* Carbon, *Sp.*

Carbon is an element of great importance, and very extensively diffused in nature. It exists in large quantity in the mineral kingdom as carbonates and as coal, and is the most abundant constituent of animal and vegetable matter. In the crystallized state it constitutes the diamond; and, more or less pure, it forms the substances called *graphite* (*black lead* or *plumbago*), anthracite and bituminous coal, coke, lampblack, animal charcoal, and vegetable charcoal. Combined with oxygen it forms carbon dioxide, or carbonic acid gas, which is a constituent of the atmosphere, and present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base it forms the carbonates, among others calcium carbonate, which is one of the most abundant minerals. There are three allotropic conditions of carbon, represented respectively by the diamond, graphite, and charcoal.

The *diamond* has been found in quantity in India, in Brazil, and in South Africa, but at the present time is obtained almost exclusively from the last named locality. Several diamonds have been found in the gold regions of Georgia and North Carolina. This gem is perfectly transparent, and the hardest and most brilliant substance in nature. Its sp. gr. is about 3.5 It is fixed and unalterable in the fire, provided air be excluded, but is combustible in air or oxygen, the product being the same as when charcoal is burned, namely, carbon dioxide. It has been made artificially at the temperature of the electric arc (2500° to 3000° C.) by Moissan.

Next to diamond, *graphite* or *plumbago* is the purest natural form of carbon. Graphite is the substance of which "black-lead" crucibles and so called lead-pencils are made. It is found in greatest purity in the mine of Borrowdale, in England, and in Ceylon, from which latter place most of the graphite of commerce is now obtained, but it also occurs very pure in this country, and in deposits at Ticonderoga, N. Y., at Stourbridge, Mass., and in Siberia, Australia, Canada, and Brazil. In physical characters it is utterly different from the diamond; it crystallizes in hexagonal plates, is very soft and unctuous, of 2 to 2.5 sp. gr., and generally contains a little ash. In connection with the production of silicon carbide (carborundum) in the electric furnace, Acheson has produced a very pure artificial graphite by simply increasing the heat until the silicon was volatilized. This artificial graphite has a specific gravity of 2.5, is soft and of high metallic luster. It is extensively used for electrodes in electro-chemical manufacturing processes, and for graphite paint. Graphite is extensively used for lubricating purposes especially in the colloidal form known as deflocculated graphite.

Anthracite, the purest variety of natural coal, occurs in different parts of the world, but particularly in the State of Pennsylvania. The best variety contains from 90 to 95 per cent. of carbon, and several per cent. of ash. Ordinary anthracite for domestic heating purposes contains from 10 to 25 per cent. of ash. *Bituminous coal* is another variety, containing, besides the fixed or free carbon, some 10 to 15 per cent. of volatile hydrocarbons or gas-making material. When this is driven off by the process of charring, as in the manufacture of coal-gas, a kind of mineral charcoal, called *coke,* is obtained, very useful in the arts as a fuel. When peat is charred, it is converted into *peat charcoal,* which forms a cheap deodorizer, which was quite generally used for this purpose at one time but which has almost completely disappeared from commerce.

Carbon may be obtained in a state approaching to purity by several processes. One method is to expose *lamp-black* to a full red heat in a closed vessel. It may also be obtained, in a very pure state, by passing the vapor of volatile oils through an ignited porcelain tube, whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. The purest lamp-black is now made from natural gas in Western Pennsylvania and in Ohio. This lamp-black is miscible with water, does not color ether, and is free from oily matter.

Colloidal carbon may be easily prepared by gradually adding 2 Gm. of sugar to 20 Gm. of sulphuric acid with continuous agitation and then pouring the mixture into 80 cc. of water and filtering. The sulphuric acid may be removed by dialysis and a clear black solution of colloidal carbon remains.

Carbon, in its uncrystallized state, is an insoluble, infusible solid, generally of a black color, and without taste or odor. It burns when sufficiently heated, uniting with the oxygen of the air, and producing carbon dioxide. Its sp. gr. in the solid state, when in mass, is 3.5. It has great power in resisting and correcting putrefaction in other bodies. When prepared from animal sources, it possesses the property of absorbing the coloring and odorous principles of most liquids. (See *Carbo Animalis.*) Its other physical properties differ according to its source and peculiar state of aggregation. As a chemical element it enjoys a very extensive range of combination. It forms two compounds with oxygen, carbon dioxide (carbonic acid gas) and carbon monoxide (carbonous oxide). With hydrogen it forms a number of compounds, called "hydrocarbons." With nitrogen, carbon constitutes cyanogen, and when united in minute proportion with iron as carbide it is present in cast iron and steel.

CARBO ANIMALIS PURIFICATUS. N. F.

PURIFIED ANIMAL CHARCOAL

"Charcoal prepared from bone, and purified by removing the substances which are dissolved by hot hydrochloric acid and water." *N. F.*

Animal Charcoal; Spodium; Ebur Ustum; Bone Black; Ivory Black; Charbon Animal Ordinaire, Noir Animal Pulvérisé, Noir d'os, *Fr.;* Thierische Kohle, Knochenkohle, Beinschwarz, Thierkohle, *G.;* Nero di ossa, Carbone animale, *It.;* Carbon animal, Carbon de hueso, *Sp.*

The animal charcoal employed in pharmacy and the arts is usually obtained from bones, by subjecting them to a red heat in closed vessels. The residue of the ignition is a black matter, which when reduced to powder forms *bone black,* sometimes incorrectly called *ivory black.*

In manufacturing bone black, the bones, first treated with steam to separate the fat, are subjected to destructive distillation in iron cylinders connected with vessels which receive the ammoniacal liquor, called *bone spirit,* together with a dark tarry liquid (*bone oil*), this being a secondary product of the operation. When the distillate ceases to come over, the residue is charred bone, or bone black. Bone consists of animal matter with calcium phosphate and carbonate. In consequence of the decomposition of the animal matter involved in this destructive distillation, the nitrogen and hydrogen, united as ammonia, and a part of the charcoal, in the form of carbon dioxide, distil over, while the remainder of the charcoal is left in the cylinder, intermingled with the calcareous salts.

Animal charcoal, as it is made by charring bones, necessarily contains bone phosphate and calcium carbonate, the presence of which does no harm in some decolorizing operations; but in delicate chemical processes these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by diluted hydrochloric acid, which dissolves the phosphate and decomposes the carbonate. For details of process see *U. S. D.,* 19th edition, p. 292. According to Stenhouse, aluminized vegetable charcoal is equally efficacious with purified animal charcoal as a decolorizer.

Description and Physical Properties.—"A dull black powder, odorless, tasteless, and insoluble in water, alcohol or other solvents.

"Boil 1 Gm. of Purified Animal Charcoal during three minutes in a mixture of 3 cc. of potassium hydroxide T.S. and 5 cc. of distilled water, and filter: the filtrate is colorless. The ash from 2 Gm. of Purified Animal Charcoal does not exceed 4 per cent. (*limit of silica and other inorganic matter*)." *N. F.*

It is more dense and less combustible than vegetable charcoal; from which, moreover, it may be distinguished by burning a small portion of it on a red hot iron, when it will leave a residue imperfectly acted on by sulphuric acid, whereas the ashes from vegetable charcoal readily dissolve in this acid, forming a bitterish solution.

The decolorizing power of vegetable charcoal was first noticed by Lowitz, of St. Petersburg; and that of animal charcoal by Figuier, of Montpellier, in 1811. In 1822 the subject was ably investigated by Bussy, Payen, and Desfosses. The decolorizing power of animal charcoal is higher than that of any other commercial product and no substitute for it is available in sugar refining and other industries where large amounts are used. In spite of the smaller percentage of carbon in animal charcoal and the well known gas absorptive power of vegetable charcoal the latter does not possess the decolorizing power of the former. It is probable that the nitrogenous constituent in animal charcoal plays an important part in the decolorozing action which is not yet thoroughly understood.

In the manufacture of potassium ferrocyanide there is obtained a fine black sediment, which has a powerful decolorizing action; this is sometimes attributed to the organic nitrogenous character of the material from which it is made.

In order to determine the commercial value of animal charcoal, Corenwinder has proposed to ascertain its power of absorbing lime from a solution of calcium saccharate of determinate strength. The value is in proportion to the absorbing power of the charcoal. A given weight of the charcoal to be tested is left in contact, for an hour, with a given volume of the solution of the saccharate, taken in excess. The liquid is then filtered, and a small measure of it saturated with diluted sulphuric acid of known strength. The less the acid necessary for this purpose, the greater the amount of lime absorbed, and the better the animal charcoal. (*Scientific American,* April 22, 1876; *A. Pharm.,* 1887; *Proc. A. Ph. A.,* 1887.) See also Laval's investigations, *P. J.,* 1900, 214. Dupuy found that the addition of a few grains of animal charcoal to a few cc. of cold fresh tincture of guaiacum immediately causes the development of a blue color, while wood charcoal does not give this reaction. (*P. J.,* 1897, 190.)

Spent animal charcoal, which has been used by the sugar refiner, may have its decolorizing power restored by calcination, which destroys the organic matters that have become fixed in it, and it is stated that it may be submitted to this process twenty times before becoming unfit for use, although this depends upon the amount of calcium salts it takes up from the raw sugars, beet sugars using up the black faster than sugars from the cane. According to Pelouze, the same object may be accomplished by subjecting it to a weak solution of potassium or sodium carbonate.

Animal charcoal is capable of taking the bitter principles from infusions and tinctures, and iodine from liquids which contain it in solution. Its power, however, of acting on solutions and chemical compounds is stated by Warington and Weppen to be more decided in its purified condition. (See *Ephem.,* 1885, p. 721.) On the other hand, Carswell (*P. J.,* 1893, 615) believes that the purification of animal charcoal is based on erroneous conclusions, as charcoal possesses no inherent powers of decolorization.

Uses.—Animal charcoal is used in pharmacy for decolorizing vegetable principles, such as gallic acid, quinine, morphine, veratrine, etc., and in the arts, principally for clarifying syrups in sugar refining, for depriving spirits distilled from grain of the penetrating impurity, called *fusel oil,* which imparts to them an unpleasant odor and taste, as first distilled, and for the filtration of petroleum residues in the manufacture of petroleum and petroleum jellies. (See *Petrolatum.*) The manner in which it is used as a decolorizer is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites with the coloring matter, and the solution by filtration is obtained white and transparent. Its use, however, in decolorizing the alkaloids and other vegetable principles, no doubt causes a loss by absorption, since it has been shown by the experiments of Lebourdais, mentioned under the head of purified animal charcoal, that several of these principles may be obtained by the sole action of charcoal. According to Guthe, a German chemist, bone charcoal, without purification, is to be preferred as a decolorizer in all cases in which the calcareous salts exert no injurious effect. Voilé uses animal charcoal as an absorbent in a pill excipient for making creosote and croton oil pills.

Because of its power in absorbing many toxic principles, animal charcoal has been recommended as an antidote in the treatment of various alkaloidal and mineral *poisonings* (Chinisse, *Press. Med.,* 1920, xxviii, 865) and, according to Secheyron (*Revue Internat. de Méd.,* 1909, p. 120), is especially to be recommended in *mushroom poisoning.* For this purpose a tablespoonful stirred up in water may be given at a dose. Knaffl-Lenz (*M. M. W.,* 1915, 625), having found that animal charcoal will absorb the proteolytic ferment of *Bacillus pyocyaneus,* employed it as a surgical dusting powder in the treatment of infected *wounds* with pleasing results. Because of its absorptive powers it has also been recommended by Adler (*W. K. W.,* 1912) in *enteritis* and by Pribran (*Pr. M. W.,* 1913) in *gastric flatulence.* Starkenstein (*M. M. W.,* 1915, No. 1) finds that the absorptive power of animal charcoal is superior to either vegetable charcoal or kaolin and recommended the drug not only in enteritis but also in *cholera* and in *dysentery.* For these latter conditions it may be administered in teaspoonful doses.

The *dose* given in the N. F. is five grains (0.3 Gm.) but much larger quantities may be safely administered.

CARBO LIGNI. U. S., Br.

WOOD CHARCOAL Carb. Lig. [Charcoal]

"Wood Charcoal prepared from soft wood, and very finely powdered." *U. S.* "Wood charcoal is wood charred by exposure to a red heat without access of air." *Br.*

Carbo Præparatus, Carbo e Ligno, Carbo Vegetabilis; Wood Charcoal, Vegetable Charcoal; Charbon Végétal, Charbon de bois, *Fr.;* Carbo Ligni Pulveratus, *P. G.;* Gepulverte Holzkohle, Holzkohle, Präparirte Kohle, *G.;* Carbone Vegetale, Carbone di legno, *It.;* Carbon vegetal medicinal, Carbon de lena, *Sp.*

Preparation on the Large Scale.—Billets of wood are piled in a conical form with a central hollow chimney or flue, and covered with earth and sod to prevent the free access of air, several holes being left at the bottom and one at the top of the pile, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while the hole at the top is closed, and, after the ignition is found to have pervaded the whole pile, those at the bottom are stopped also. The combustion taking place with a smothered flame, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon is left, a portion of it, however, being lost by combustion. Wood, thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in 100 of excellent charcoal; and, at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Aceticum.*) A method of preparing charcoal by subjecting wood to superheated steam has been invented by Violette. When the temperature of steam is 300° C., the wood is converted into a peculiar charcoal, called *ed charcoal,* which is intermediate in its qualities between wood and ordinary charcoal. When the temperature is lower, the carbonization is incomplete; when higher, the product is black charcoal. The steam process yields a uniform charcoal for a given temperature, which may be easily regulated, and a product about double that obtained in closed cylinders. Charcoal contains carbon, approximately in proportion to the temperature at which it is formed; varying from 65 per cent. when made at 250° C. to 80 per cent. when made at 400° C. The gaseous matter present, on the other hand, decreases with the temperature of carbonization. Thus, for charcoal made at 300° C. it is one-third of its weight; at 350° C., one-fourth.

E. C. C. Stanford has called attention to a variety of vegetable charcoal, obtained by charring a species of sea weed, *Laminaria digitata,* gathered on the shores of the Hebrides, which, on account of the large proportion of calcium carbonate contained in it (20 per cent.), is unfit for use in refining sugar; it, however, possesses more of the deodorizing and decolorizing power than animal charcoal itself, which, with the exception referred to, it closely resembles in chemical composition. The charcoal from nut shells and the pits of such drupes as the plum, peach, etc., was found to have extraordinary absorptive power for gases during the World War, and was much in demand in connection with the manufacture of gas masks.

Preparation for Medicinal Use.—Belloc recommends that charcoal for this purpose be obtained from poplar shoots, cut at the time the sap rises, and deprived of their bark. The carbonization should be performed in cast iron vessels at red-white heat. The product is a light and brilliant charcoal, which must be purified by being macerated for three or four days in water, frequently renewed. It is then dried, powdered, and placed in bottles, which should be well-stoppered. The charcoal made from willow is generally preferred, although that obtained from maple is also largely employed. A fine charcoal is also made in Europe from the linden and poplar.

Properties.—Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat.

It possesses the properties not only of absorbing many times its own bulk of certain gases but also will adsorb many chemicals from their solutions; Kolthoff (*Ph. Wb.,* 1921, lviii, p. 630) found it would adsorb iodine, phenol, mercuric chloride, methylene blue, and various alkaloids, etc. Rosenberg tested the adsorptive powers of various kinds of charcoal with methylene blue; he found that taking the absorptive properties of blood charcoal as 100, that of willow charcoal was 24, and charcoal from a drug store 14 (*Ph. Ztg.,* 1921, lxvi, p. 724).

Description and Physical Properties.—" A black, odorless, and tasteless powder, free from gritty matter. Wood Charcoal burns without a luminous flame, yielding not more than 7 per cent. of ash. Boil 1 Gm. of Wood Charcoal with a mixture of 3 cc. of potassium hydroxide T.S. and 10 cc. of distilled water for one-half minute, and filter: the filtrate has only a slight brown color.

" Preserve in well-closed vessels." *U. S.*

The British Pharmacopœia describes it as " A black powder without odor or taste, free from gritty matter. When 1 gramme of the Charcoal is boiled for a few minutes with 5 millilitres of *solution of sodium hydroxide* diluted with 15 millilitres of *water* and the mixture filtered, the color of the filtrate is not deeper than pale yellow (absence of insufficiently carbonised wood). Ash not more than 7.5 per cent." *Br.*

When exposed to the air after ignition, charcoal increases rapidly in weight, absorbing from 12 to 14 per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, amounting to 1 or 2 per cent., which is left as ashes when the charcoal is burned. This inorganic material may be removed by digesting the charcoal in diluted hydrochloric acid, and afterwards washing it thoroughly with boiling water. Havenhill examined the wood charcoal of the western markets and found the ash to vary from 0.62 to 16.80 per cent. (*D. C.,* 1914, p. 260.) Gane states that imperfectly carbonized samples are of frequent occurrence (*J. A .Ph. A.,* 1912, p. 375). Knecht claims that the more closely the substance approaches in composition to pure carbon the less is its decolorizing power. (*Proc. VIIth Internat. Congress App. Chem.,* Sec. IVb., Coloring, 1909, London, 1910, pp. 17, 18.)

For internal use charcoal is preferred by some in a *granular form* and sweetened. For on account of the method of preparing it in this manner see *U. S. D.,* 20th ed., p. 291.

It has been shown that the presence of certain salts in charcoal increases the absorptive power while others decrease the effect remarkably. Zinc chloride, stannous chloride and magnesium chloride have been found especially valuable as activators.

Eponite and *Norite* are patented forms of vegetable carbon with great decolorizing activity. Microscopic examination of these products revealed the fact that they are probably made from coniferous woods activated by special treatment with calcium or magnesium compounds.

Dorsite is another form of activated charcoal especially useful in gas masks. D. Van Oos (*Pharm. Weekbl.,* 1920, lvii, p. 693) has conducted exhaustive comparative experiments in connection with the selective action of especially activated charcoals.

Stenhouse has devised a process for combining alumina with common vegetable charcoal, forming what he calls *aluminized charcoal,* which is an economical substitute for purified animal charcoal, and equally efficacious as a decolorizer. It is prepared by digesting finely powdered charcoal with sufficient of the solution of aluminum sulphate to give an impregnation of 7.5 per cent. of alumina. The whole is evaporated to dryness, and ignited in a covered Hessian crucible, until the water and acid have been dissipated. Aluminized charcoal is perfectly black, though thoroughly impregnated with anhydrous alumina, and only requires to be carefully pulverized to be ready for use. On similar principles, Stenhouse prepares his *artificial bone black,* by impregnating powdered wood charcoal with 7.5 per cent. of calcium phosphate, by digesting it in a solution of this salt in hydrochloric acid, evaporating to dryness, and igniting in covered vessels. This charcoal decolorizes well, but can be used only for neutral solutions.

Uses.—Charcoal is used in medicine chiefly for its absorbent properties, thus it is used locally in *gangrene* and *foul ulcers* to absorb the putrid gases. Internally it has been used in *meteorism* and *fermentative dyspepsia* with the idea of absorbing the gas. In many cases of *dyspepsia,* however , it appears to have some further action than that of a mere absorbent. Calvert (*J. A. Ph. A.,* 1922, xi, 798) has shown that while moist charcoal has only small power to absorb carbon dioxide it exercises a marked inhibition on yeast fermentation. As is well known, charcoal is capable of adsorbing not only coloring matter but many other organic substances and it has been lauded by Kraus and Barbara (*D. M. W.,* 1915, xli) as an absorbent for toxins. For this action they recommend it internally in the treatment of *diarrhea* and *dysentery* and locally for various infected *wounds;* see also Eisner. (*Ther. Geg.,* lvi.) Oppenheim and Schlifka (abs. *J. A. M. A.,* 1915, lxvii, 1432) have reported excellent results from the injection of a 1 per cent. suspension of charcoal in acute *gonorrhea.*

At one time it was much used as a dressing for ulcers but is at present rarely employed, though the *Cataplasma Carbonis* or charcoal poultice is still occasionally prescribed in Great Britain. Several of its varieties are used as tooth powder. Those generally preferred are the charcoals of the cocoa-nut shell and of bread. It is said that charcoal proves useful in preserving the teeth by absorbing the acid sometimes morbidly present in the mucus of the mouth.

It has long been recommended as an antidote in various forms of poisoning and is one of the ingredients of the mixture sometimes called universal antidote which consists of charcoal, tannic acid and magnesia. There seems to be little doubt that large quantities of charcoal will delay the entrance of many poisons into the system and therefore may be of value, but it is scarcely proper to speak of it as antidotal as it does not destroy the toxicity of the poison but simply delays its absorption. Scoville states that charcoal is a good antidote for phenol poisoning. It acts by absorbing phenol and eliminating it through the intestines rather than through the kidneys. (*Bull. Pharm.,* 1913, p. 393.)

Dose, ordinarily five to twenty grains (0.32 to 1.3 Gm.) but it has been used in teaspoonful doses.

Off. Prep.—Trochisci Carbonis Ligni, *N. F.*

CARBON DISULPHIDUM. Br.

CARBON DISULPHIDE

"Carbon Disulphide, CS_2, may be obtained by combining carbon and sulphur at a high temperature, the product being subsequently condensed and purified." *Br.*

Carbonis Bisulphidum, *Br.,* 1898; Carbon Bisulphide; Carbon Sulphide; Sulphururum Carbonicum; Carbo Sulfuratus, Sulfure de Carbone, *Fr. Cod.;* Bisulphide de Carbone, *Fr.;* Carboneum Sulfuratum, Alcohol Sulfuris, Schwefelkohlenstoff, Kohlensulfid, Schwefelalkohol, *G.;* Solfuro di carbonio, *It.;* Sulfuro de carbono, *Sp.*

This compound is prepared by the direct combination of carbon and sulphur at a moderate red heat. To effect this, charcoal is heated to redness in a vertical cylinder, while sulphur is admitted through a lateral tubulure near the bottom. As the sulphur melts and vaporizes, it combines with the carbon, and the carbon disulphide formed distils over through a series of condensing tubes, which, while they serve to collect the crude carbon disulphide, allow of the escape of the hydrogen sulphide formed at the same time. The crude product is then rectified, first over a solution of chlorinated lime to break up any hydrogen sulphide gas remaining, and then repeatedly either over mercury, mercuric chloride, anhydrous cupric sulphate, or over a pure fatty oil, which withdraws from it all free sulphur and malodorous sulphur compounds.

The most decided improvement in the manufacture of carbon disulphide was made by E. R. Taylor of Penn Yan, New York, who introduced a patented electrothermal process which can be worked continuously. In large furnaces 41 feet high by 16 feet in diameter an alternating current is applied through carbon electrodes. The sulphur passing over the electrodes is vaporized and rises through the glowing carbon, the carbon disulphide being taken off as vapor through a side connection near the top of the furnace. The impure carbon disulphide is purified by forcing lime water in a fine spray through the disulphide liquor until the water runs out of the tank colorless. The carbon disulphide is finally rectified by steam heat. It is used in the arts for the extraction of oils from different oil seeds, for the extraction of sulphur from some varieties of sulphur ores, for the cleansing of wool and recovering the fat, as a solvent for caoutchouc in the manufacture of India rubber goods, for the extraction of perfumes, and on an enormous scale in France as a remedy against the *phylloxera.* It is also used to exterminate rodents and other ground burrowing animals, by pouring a small quantity into each burrow. Its vapor being heavier than air penetrates to the innermost recesses of the burrow and being very toxic the animal dies underground. Von Lengyel describes a carbon sulphide having the composition C_3S_2. (*Proc. A. Ph. A.*, 1893, 1021.)

Properties.—Carbon disulphide is included among the Reagents in the U. S. (see Part III).

"A clear, colorless, highly refractive liquid. Odor charactristic but not fetid. Specific gravity 1.268 to 1.269. Highly inflammable, burning with a blue flame and giving off carbon dioxide and sulphur dioxide. Boiling point 46° to 47° C. Vapor mixed with air is explosive in contact with flame. Evaporated spontaneously in a glass vessel, it leaves no residue (absence of free sulphur)." *Br.*

Uses.—Although carbon disulphide has been recommended by Taar (*B. Thier., W.*, 1907, p. 406) for the destruction of intestinal parasites in the horse, it has not found its way into human medicine as an internal remedy. It is, however, occasionally used externally as a counter-irritant and local anesthetic. Turnbull especially recommended it as an external application in *enlarged lymphatic glands.* He applied it by means of a bottle with a proper sized mouth, containing a fluidrachm of the disulphide, imbibed by a piece of sponge; the skin over the gland is first well moistened with water. He employed the vapor also with benefit in deafness, when dependent on want of nervous energy and a deficiency of wax. For this purpose, the bottle containing the disulphide is made with a neck to fit the meatus, and, being applied to the ear, is held there until considerable warmth is produced. The remedy has been used often with very good results, in a similar manner, in *facial* and other *neuralgias* and various local *pains.* It causes a good deal of smarting, but its disagreeable odor is the chief objection to it. In France the disulphide has been used in *diarrhea* in 3.5 per cent. solution, of which the dose is two tablespoonfuls (30 cc.) four or five times a day.

Its most important use is as a solvent, especially for rubber. Carbon disulphide is an active poison and workmen exposed to the fumes of the disulphide are affected with headache, vertigo, and over-excitement of the nervous system, as evinced by voluble talking, incoherent singing, or immoderate laughter, or sometimes by weeping; and a continuance of the exposure is apt to finally cause a state of cachexia, characterized by general weakness, loss of sexual appetite, dullness of sight and hearing, and impairment of memory. Some writers assert that these phenomena are hysterical, and that what the carbon disulphide does is to produce an hysterical neurosis. (See *Annales de Hygiène*, 1895, xxxiii.) The swallowing by a man of half an ounce of carbon disulphide was followed in half an hour by absolute unconsciousness, very rapid, feeble pulse, slow and stertorous respiration, cold and clammy surface of body, and insensitive conjunctiva, with mobile pupils. Two hours later, death occurred. The blood was found fluid, but there was no marked lesions of irritation in the gastro-intestinal mucous membrane. (*L. L.*, July 17, 1886.) India rubber workers, by whom the disulphide is largely used, are said to suffer frequently from paralytic symptoms. (*L. L.*, Jan., 1886.)

CARBONEI TETRACHLORIDUM. U. S.

CARBON TETRACHLORIDE Carb. Tetrachlor.

"Tetrachlormethane [CCl_4]." *U. S.*

Carbonei Tetrachloridum; Tetrachlormethane; Carboneum Chloratum; Chlorocarbon; Carbon Perchloride; Tétrachlorure de Carbone, Formène Perchloré, *Fr.*; Chlorkohlenstoff, *G.*

Carbon tetrachloride was discovered by Regnault in 1839. It may be prepared by passing the vapor of carbon disulphide with dry chlorine through a red hot porcelain tube. The vapors from this condensed in a well-cooled receiver form a yellowish-red liquid, which is a mixture of carbon tetrachloride and sulphur chloride. The latter substance is removed by slowly adding potassium or calcium hydroxide, the mixture being set aside and agitated from time to time until the sulphur compound is decomposed; the carbon tetrachloride is then recovered by distillation.

Carbon tetrachloride is extensively used as a solvent for fats and for removing grease from garments, replacing petroleum benzine to advantage because of its non-inflammability; proprietary forms used for the latter purpose are known under the trade names respectively of *carbona* and the misnomer *benzinoform.* It is likewise employed as a solvent for alkaloids in assay work and manufacturing processes instead of chloroform. It is also of value as a fire extinguisher and forms the basis of the fluid called *pyrene.* When used, however, to extinguish fires, it generates large volumes of hydrochloric acid gas and in limited spaces may be dangerous, not only from this cause, but also on account of the carbon dioxide formed and the vaporization of undecomposed carbon tetrachloride. It is a good solvent for caoutchouc; and such a solution was at one time suggested for the purpose of coating the hands of the surgeon with a sterile and impermeable covering.

Description and Physical Properties.—"A clear, colorless, mobile liquid. It has a characteristic, ethereal odor, resembling that of chloroform. It is not inflammable. It is slowly decomposed by light if moisture is present.

Carbon Tetrachloride is soluble in 2000 times its volume of water. It is miscible with alcohol, chloroform, ether, benzene, and with petroleum benzin, and dissolves most of the fixed and volatile oils. Specific gravity: from 1.588 to 1.590 at 25° C. Carbon Tetrachloride boils between 76° and 77° C., but volatilizes at lower temperatures.

"Evaporate 50 cc. of Carbon Tetrachloride in a dish on a water bath to about 1 cc., and allow to evaporate spontaneously to dryness: the residue, if any, is odorless. Now dry at 100° C., and weigh: the weight of the residue does not exceed 0.001 Gm. Shake 15 cc. of Carbon Tetrachloride with 25 cc. of distilled water during five minutes, and allow the liquids to separate completely: the aqueous layer is neutral to litmus paper, and 10 cc. portions are not affected by a few drops of silver nitrate T.S. (*chloride*), nor colored blue by the addition of a few drops each of potassium iodide T.S. and starch T.S. (*free chlorine*). Warm 10 cc. of Carbon Tetrachloride with 10 cc. of a 25 per cent. potassium hydroxide solution for five minutes at about 60° C. with frequent agitation: no yellow or brown color develops in either liquid (*aldehyde*). Transfer 20 cc. of Carbon Tetrachloride to a glass-stoppered cylinder previously rinsed with sulphuric acid. Add 5 cc. of sulphuric acid, shake vigorously for five minutes, and allow the liquids to separate completely: the sulphuric acid layer is colorless or nearly so (*readily carbonizable substances*). Mix 10 cc. of Carbon Tetrachloride with an equal volume of a 10 per cent. potassium hydroxide solution in dehydrated alcohol, and allow the mixture to stand for one hour. Add 5 cc. of acetic acid, and follow with 1 cc. of copper sulphate T.S.: no yellow precipitate is formed within two hours (*carbon disulphide*).

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—Carbon tetrachloride is a powerful narcotic, indeed, the assertion is made by Freymuth (*B. K. W.*, 1921, lviii, p. 1330) that it surpasses chloroform in the vigor of its action. It is, however, depressant to the circulation and therefore not available as a surgical anesthetic. Foster (*U. S. Pub. Health Rep.*, October 25, 1918) has found that carbon tetrachloride is very efficient for the destruction of lice in clothing. Although it was occasionally employed as a local remedy, it attracted little medical attention until 1922 when it was brought forward as a remedy for *hookworms* by Lake (*U. S. Pub. Health Rep.*, May 12, 1922). He found that a dose of 3 cc. (forty-seven minims) was an efficient anthelmintic and that monkeys could take a hundred times the proportional dose without serious intoxication. Lambert (*J. A. M. A.*, 1922, lxxix, 2055) has treated 20,000 cases of hookworm infestation with carbon tetrachloride. In 90 per cent. of the patients a single treatment with a dose of from 3 to 4 cc. (forty-five to sixty minims) caused complete cure. In a few cases the patients complained of a dull headache and nausea, and in a number of instance of drowsiness, but in the whole series there was not a single fatality. In a subsequent communication Lambert (*J. A. M. A.*, 1923, lxxx, 526) reported three deaths from the treatment; these he attributed, however, to impurities in the commercial samples of carbon tetrachloride employed. McVail (*Indian Med. Gaz.*, 1922, lvii, 290) finds that carbon tetrachloride is efficacious against *ankylostoma* and the *oxyuris* but is of little service against the *ascaris*. The drug is of special value in community campaigns against the hookworm because of its relative cheapness and the acceptability to the palate. It should be preferably given on an empty stomach and followed three hours later with a purgative dose of magnesium sulphate. It may be administered by placing the determined quantity in a tablespoon, covering with sugar, and swallowing the whole at once.

Colman (*L. L.*, June 22, 1907) has reported poisoning from the use of carbon tetrachloride in dry shampoos.

Warren (*A. J. P.*, 1923, xcv, 864) gives extensive literature on the use of carbon tetrachloride as an anthelmintic, gives a method for determination of carbon disulphide, also analysis of several commercial samples showing a specific gravity of from 1.5879 up to 1.5897, and a carbon disulphide from 0 up to 0.22 per cent.

Lamson *et al* (*J. P. Ex. T.*, 1923, xxii, 215) find that the oral toxic dose of carbon tetrachloride for dogs is at least seven times as large as that required for rabbits, the difference being due to the absorbability from the intestines. They further find that the simultaneous exhibition of fatty substances or of alcohol increases the absorption and therefore the poisonous effects of the drug.

Dose, thirty to sixty minims (2–4 cc.).

CARBROMALUM. U. S.

CARBROMAL Carbrom. [Bromdiethylacetylurea]

"Brom-diethylacetyl carbamide [$C(C_2H_5)_2Br.CONH.CONH_2$]." *U. S.*

This remedy, which was originally introduced under the proprietary name of *Adalin*, is prepared from diethyl acetic acid by first converting this into a bromine derivative $(C_2H_5)_2CBrCOBr$ (bromo-diethyl-acetyl bromide) and then bringing about a reaction between this compound and urea.

Carbromal contains about 36 per cent. of combined bromine.

Description and Physical Properties.—"A white, crystalline, odorless powder. One Gm. of Carbromal is soluble in about 3000 cc. of water, 18 cc. of alcohol, 3 cc. of chloroform, and in 14 cc. of ether, at 25° C. It is very soluble in boiling alcohol. It dissolves in sulphuric, nitric, and in concentrated hydrochloric acids, from which it is precipitated by dilution with water. It is dissolved by solutions of alkali hydroxides.

" Carbromal melts between 116° and 117° C. On boiling about 0.2 Gm. of Carbromal with 5 cc. of a 10 per cent. aqueous sodium hydroxide solution, ammonia is evolved. Mix 0.1 Gm. of Carbromal with 0.5 Gm. of anhydrous sodium carbonate, and ignite gently until completely decomposed. Dissolve the residue in 5 cc. of hot distilled water, cool, acidulate with acetic acid, and filter: Add to the filtrate 2 cc. of chloroform and then chlorine T.S., drop by drop: the chloroform acquires a red-brown color on shaking.

" The ash from 0.5 Gm. is negligible. A solution of 0.2 Gm. of Carbromal in 2 cc. of sulphuric acid is colorless or at most faintly brown (*readily carbonizable substances*). Shake 1 Gm. of Carbromal with 20 cc. of distilled water during five minutes, and filter: the filtrate is neutral to litmus paper. Five cc. portions of the filtrate obtained in the preceding test show no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid, and no more *sulphate* than corresponds to 0.1 cc. of fiftieth-normal sulphuric acid." *U. S.*

Uses.—This compound was introduced into medicine with the idea that it would combine the sedative effects of bromine with the narcotic action of the aliphatic series. Impens (*Ther. Geg.*, 1912, p. 158) has shown that it is partially broken up in the system, eliminated in part as an inorganic bromide but also some of it in the undecomposed state. As the drug represents, however, only approximately 34 per cent. of bromine, in view of the smallness of the dose which is employed it seems highly improbable that this element can play any important part in the action of the drug. This conclusion is borne out by the experiments of Takeda (*A. I. P. T.*, 1911, xxi, p. 203) who concluded from a study of the distribution of the drug in the body that its action must be due to the whole molecule.

Carbromal, in sufficient dose, possesses the somnifacient effects of its aliphatic allies and is frequently used in the milder forms of *sleeplessness.* In severe types of insomnia, however, it is greatly inferior to barbital and some other drugs. Its most important use is as a general nerve sedative in *neurasthenia, hysteria, epilepsy, whooping-cough,* and other similar conditions of hyper-irritability of the central nervous system. It differs from most of the other narcotics of this group in that it possesses marked analgesic properties and is often a remedy of great usefulness in *neuralgia* and other forms of *pain.*

With ordinary caution carbromal seems to be a very safe drug. Nieuwenhuijse (*P. J.*, 1916, xcvi, p. 327) reports a case in which forty-five grains were taken but the patient recovered after sixty hours of narcosis. We know of no other instance of ill-effects from the use of this drug.

The ordinary *dose* as a nerve sedative is from five to ten grains (0.3–0.6 Gm.), as a hypnotic, from ten to fifteen grains (0.6–1 Gm.).

CARDAMOMI SEMEN. U. S. (Br.)

CARDAMOM SEED Cardam. Sem.

" Cardamom seed is the dried ripe seed of *Elettaria Cardamomum* White et Maton (Fam. *Zingiberaceæ*). Cardamom seed yields not more than 5 per cent. of acid-insoluble ash." *U. S.* " Cardamom Seeds are the dried ripe seeds of Elettaria Cardamomum, *Maton.* The seeds should be kept in their pericarps and separated when required for use." *Br.*

Cardamomi Semina, *Br.*; Cardamomum Minus, Cardamomum Malabaricum; Malabar Cardamoms, Cardamoms; Cardamome du Malabar, Petit Cardamome, *Fr.*; Fructus Cardamomi, *P. G.*; Malabar Kardamomen, Kardamomen, Kleine Kardamomen, *G.*; Cardamomo minore, *It.*; Cardamomo, Cardamomo menor, *Sp.*

The fruit of cardamom is official in most of the Pharmacopœias. The U. S. Pharmacopœia in its definition confines cardamom to the seeds. In this it follows the British Pharmacopœia which has always limited the drug to the seeds, but specifically states that the fruit should be kept intact and the seeds separated when required for use. This step was probably a wise one as there has always been some confusion by manufacturers as to whether the article designated as cardamom in a formula was restricted to the seeds or not. On the other hand the pericarp contains some oil and forms an excellent surface for the grinding of the seeds. Furthermore, the decorticated seeds are liable to adulteration with seed of wild cardamom and other foreign seeds which are not detected except upon careful examination.

The term cardamom has been applied to the aromatic capsules of various plants, most of them from India, belonging to the family of *Zingiberaceæ.* Formerly the terms *lesser, middle* and *larger* cardamoms were used to separate these various fruits, but these words have been used so differently by various writers that they no longer possess any precise signification. The *lesser cardamom* of most writers is the variety recognized by the Pharmacopœias and generally kept in the shops. The other varieties, though circulating to some extent in European and Indian commerce, are little known in this country.

The official cardamoms are produced chiefly in Malabar, Mysore, and adjacent regions of India and Ceylon. They have also been cultivated in some extent in tropical America.

The cardamom plant is a perennial herb with a tuberous horizontal rhizome, sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate elliptical-lanceolate sheathing leaves. The flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in a panicle. The fruit is an ovoid, three-celled, loculicidally dehiscent capsule, containing many seeds which are covered by an aril; during drying it is said to lose three-fourths of its weight.

This valuable plant is a native of the mountains of Indo-China, where it springs up spontaneously in the forests after the removal of the undergrowth, and is very extensively cultivated by the natives. For a detailed account of culture, see *P. J.*, 1888; *Bull. des Sc. Pharmacol.*, 1906, pp. 114 and 584 and *Ph. Era*, 1920, liii, 365. The plant begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules just before complete maturity are picked from the fruit-stems, dried over a gentle fire or by sun-heat, and separated, by rubbing with the hands, from the footstalks and adhering calyces. They are then washed and bleached by exposure either to dew and sun or to vapors of burning sulphur. J. W. Mollison describes the method of washing and curing cardamoms employed in the Bombay Presidency, India. The washing and manipulation is performed by women, and water from special wells is employed. The cardamoms are first washed in earthenware vessels containing a mixture of the well water with pounded soap nut and a species of acacia, in the proportion of two pounds of the former to a quarter pound of the latter. About ten pounds of cardamoms are treated at one time. Two women stir them vigorously in the mixture for about one minute and then allow them to rest about an equal length of time, and again stir for another minute. A thick lather results. This completes the first washing, after which the cardamoms are baled out by hand into a basket where they are allowed to drain for a few seconds, and then subjected to a second washing similar to the first except that the mixture contains less of the soap nut preparation and an additional quantity of soap solution. They are then thrown upon a mat and sprinkled with water from the special well at intervals of a half hour, until the next morning, when they are spread upon the roof of a house and allowed to dry for four or five hours. After nipping off the short stalk, an operation performed with a large pair of shears, the cardamoms are sorted, only the most plump fruits being prepared for the foreign market. Besides bleaching by this process, cardamoms are also subjected to starching in India. The starched product has a whiter appearance than the bleached cardamoms. (*B. C. D.*, 1904, see also *Ph. Era*, 1904, 137.)

The fruits, thus prepared, are ovate-oblong, from 10 to 17 mm. long, from 6 to 8 mm. thick, three-sided with rounded angles, obtusely pointed at both ends, longitudinally wrinkled, and of a yellowish-white color. The seeds constitute about 74 parts per cent. by weight. According to Pereira, three varieties are distinguished in commerce: 1, the *shorts*, from 6 to 12 mm. long, from 4 to 6 mm. broad, browner and more coarsely ribbed and more highly esteemed than the others; 2, the *longlongs*, from 14 to 25 mm. in length by 4 to 6 mm. in breadth, elongated, and somewhat acuminate; and 3, the *short-longs*, which are somewhat shorter and less pointed than the second variety. The odor of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic.

Most of the drug goes through Bombay and Madras to the various parts of the world. That imported into the United States is either shipped direct from Colombo, Ceylon, and Bombay, India, or through London. Malabar cardamom comes from Colombo; Mysore cardamom from Bombay.

UNOFFICIAL VARIETIES.—Besides the official cardamoms the fruit of a large number of related plants has been more or less employed. The more important of these are noted below.

Ceylon Cardamom.—This has been denominated variously *cardamomum majus* and *cardamomum longum*, and is sometimes termed in English commerce *wild cardamom.* It is the *large cardamom* of Guibourt. In the East it is sometimes called *grains of Paradise;* but it is not the product known with us by that name. (See below.) It is derived from a plant cultivated in Candy, in the Island of Ceylon, and also growing wild in the forests of the interior, which was designated by Sir James Edward Smith *Elettaria major,* but is now generally acknowledged to be only a variety of the official plant. (*Elettaria Cardamomum* var. *β-Major* Smith.) The fruit is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about 3.5 cm. long and 6 to 8 mm. broad, with flat and ribbed sides, tough and coriaceous, brownish or yellow ash-colored, having frequently at one end the long, cylindrical, three-lobed calyx, and at the other the fruit-stalk. It is three-locular, and contains angular, rugged, yellowish-red seeds, of a peculiar fragrant odor and spicy taste. Its effects are analogous to those of the official cardamom.

Round or *Siam Cardamom.*—This is probably the Ἄμωμον of Dioscorides and the *Amomi uva* of Pliny, and is believed to be the fruit of *Amomum cardamomum* Willd., growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish-white, and sometimes reddish, with brown, angular, cuneiform, shrivelled seeds, which have a spicy camphoraceous flavor. They are sometimes, though rarely, met with connected in their native clusters, constituting the *amomum racemosum,* or *amome en grappe,* of the French. They are similar in medicinal properties to the official, but are seldom used except in the southern parts of Europe.

Java Cardamom.—The plant producing this variety is supposed to be the *Amomum maximum* Roxburgh, growing in Java and other Malay islands in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from 1.5 to 3 cm. long, and from 8 to 15 mm. broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown color, and coarse fibrous appearance. When soaked in water, they exhibit as their distinguishing character from nine to thirteen ragged membranous wings along their whole length. The seeds have a feebly aromatic taste and odor. This variety of cardamom affords but a very small proportion of volatile oil, and is altogether of inferior quality.

Madagascar Cardamom.—This is the *Cardamomum majus* of Geiger and some others, and is thought to be the fruit of *Amomum angustifolium,* of Sonnerat, growing in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, corrugated margin. The seeds have an aromatic flavor similar to that of official cardamom.

Bengal Cardamom.—The fruit of *Amomum aromaticum* Roxb., sometimes known by the name of winged Bengal cardamom. *Morung elachi,* or *Buro elachi,* is about 2.5 cm. in length, obscurely three-sided, ovoid or somewhat obconic, with nine narrow, jagged ridges or wings (best seen after soaking in water) upon its distal end, which terminates in a truncate bristly nipple. The taste is somewhat camphoraceous.

Nepal Cardamom is produced by an *Amomum* of undetermined species probably *A. subulatum* Roxb. and resembles the Bengal cardamom, except in having a long tubular calyx on its summit, and in being usually attached to a stalk.

Grains of Paradise. Grana Paradisi.—Under this name and that of *Guinea grains,* and *Melegueta* or *Mallaguetta pepper,* are found in commerce small seeds of a round or ovate form, often angular, and somewhat cuneiform, minutely rough, brown externally, white within, of a feebly aromatic odor when rubbed between the fingers, and of a strongly hot and peppery taste. Two kinds of them are known in the English market, one larger, plumper, and more warty, with a short conical projecting tuft of pale fibers on the umbilicus; the other smaller and smoother and without the fibrous tuft. The latter are the more common. It is probable that these are produced by *Amomum Melegueta* Roscoe, although they have been ascribed also to the *A. Grana Paradisi* J. E. Smith. Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give pungency to spirits, wine, beer, and vinegar. J. C. Thresh made a proximate analysis of the seeds, and found volatile oil, resin, tannin, starch, albuminoids, and an active principle in the form of a straw-colored viscid, odorless fluid, pungent, but not so hot as capsaicin. (*P. J.,* 1884, p. 297.) Fred'k Schwartz found in the seeds a reddish-brown acrid resin, and an oil having a burning aromatic taste, upon which the virtues probably depend. (*A. J. P.,* 1886, 118; consult also Hanausek's researches in *Chem. Ztg.,* 1893, 1765.)

Bastard or *Wild Cardamom,* the seeds of *Amomum Xanthioides* Wall., resembles true cardamom in appearance, but is of a dirty green color, and has a very biting, camphor-like taste. They come from Siam.

Description and Physical Properties.—"*Unground Cardamom Seed.*—Mostly agglutinated into groups of 2 to 7 by the adhering membranous aril, the individual seeds oblong-ovoid or irregularly 3- to 4-sided, from 3 to 4 mm. in length; convex on the dorsal surface, strongly longitudinally grooved on the ventral side and coarsely tuberculated; externally reddish-gray brown; odor aromatic; taste aromatic and pungent.

"*Structure.*—Seed coat: an epidermal layer of thick-walled cells, a pigment layer of small cells with brownish contents, a layer of volatile oil cells with suberized walls and a single layer of radially elongated strongly lignified stone cells with inner walls heavily thickened. Perisperm large, white, surrounding a central, greenish endosperm enclosing a small straight embryo.

"*Powdered Cardamom Seed.*—Brown; endosperm and perisperm cells filled with starch grains from 0.001 to 0.004 mm. in diameter or containing one or more prisms of calcium oxalate from 0.010 to 0.025 mm. in diameter; fragments of seed coat with dark brown cells polygonal in surface view and about 0.020 mm. in diameter; fragments of spiral tracheæ with accompanying slightly-lignified bast-fibers relatively few." *U. S.*

"Fruits from one to two centimetres long, ovoid or oblong, bluntly triangular in section, shortly beaked at the apex, pale buff in color, plump and nearly smooth or with slight longitudinal striations. Seeds dark reddish-brown, about three millimetres in length and the same in breadth and thickness, irregularly angular, transversely wrinkled, and enclosed in a thin, colorless, membranous aril. The powdered Seeds exhibit abundant, minute, angular starch grains, often compacted into masses; but no spiral vessels, sclerenchymatous fibres, or strongly elongated sclerenchymatous cells (absence of pericarps). Aromatic odor; taste agreeably warm and aromatic. Ash not more than 6 per cent." *Br.*

The seeds contain 4.6 per cent. of volatile oil, 10.4 of fixed oil, 2.5 of a salt of potassium mixed with a coloring principle, 3.0 of starch, 1.8 of nitrogenous mucilage, 0.4 of yellow coloring matter, and 77.3 of ligneous fiber. (Trommsdorff.) The volatile oil is colorless, of an agreeable and very penetrating odor, and of a strong aromatic, burning, camphorous, and bitterish taste. It is dextrogyrate, and consists essentially of a terpene, $C_{10}H_{16}$, with small quantities of formic and acetic acids. From old specimens of oil Dumas and Peligot claim to have separated crystals of terpene hydrate, $C_{10}H_{20}O_2 + H_2O$, while Flückiger has obtained a crystalline deposit from Ceylon oil which he considers identical with common camphor. Weber (*Ann. Ch. Ph.,* ccxxxviii, 98) found a small amount of a crystalline, non-volatile compound which fuses at 60° to 61° C. Schimmel

& Co. published in their semi-annual reports for April and October, 1897, some results of investigation of several varieties of cardamom oil. The terpenes of Ceylon oil they state to be terpinene and dipentene; both Ceylon and Bengal cardamom contain cineol; Malabar cardamom yields terpineol as well as cineol, while Siam cardamom yields a crystalline sediment composed of borneol and camphor in approximately equal proportions. The sp. gr. of the oil is between 0.92 and 0.94. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odor and taste. If ether be made to percolate through the powdered seeds, and the liquor obtained be deprived of the ether, a light greenish-brown fluid remains, consisting almost exclusively of the volatile and fixed oils. It has the odor of cardamom, and keeps better than the oil obtained by distillation. (*A. J. P.*, xxi, 116.) The oil of cardamom of commerce is often factitious, being composed of several cheap volatile oils, oils of cajuput, nutmeg, and others being used. Schimmel & Co. announced in 1901 that they no longer distilled the oil from the fruit of *Elettaria cardamomum*, but from the seeds of another species; this oil makes a clear solution with three parts by volume of 70 per cent. alcohol. (*Schim. Rep.*, 1901, 14.) See *Oleum Cardamomi*. The seeds should be powdered only when wanted for use, as they retain their aromatic properties best while in the capsule.

Cardamoms are sometimes adulterated; G. W. Kennedy reported nearly 4 per cent. of orange seeds and unroasted grains of coffee admixed with cardamom. Solstein (1892) found three commercial samples of powdered cardamom containing sodium carbonate.

Uses.—Cardamom is a grateful aromatic, not strongly heating or stimulating, and useful chiefly as an adjuvant. Throughout the East Indies it is largely consumed as a condiment. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Dose, fifteen to thirty grains (1–2 Gm.).

CARMINUM. N. F.

CARMINE Carmina.

Carmine Lake; Chinese, Florentine, Hamburg, Munich, Roman or Venetian Lake; Carmin, *Fr. Cod.;* Karmin Lack, *G.*

"The aluminum lake of the coloring principle obtained from cochineal." *N. F.*

The term *lakes* is applied to a group of coloring substances which are salts of an animal or vegetable coloring matter united with a metal generally aluminum or tin. Carmine is a combination of *carminic acid* (see under *Coccus*), obtained from cochineal, with aluminum. (See also *Lakes,* Part II.)

Description and Physical Properties.—"It occurs in irregular, angular, bright red fragments or as a powder, without odor or taste. When burned, Carmine emits an odor resembling that of burned feathers. Slightly soluble in water to which it imparts a red color; freely soluble in ammonia water and alkaline liquids, forming a dark purplish red solution.

"The yield of ash does not exceed 12 per cent. Fuse the ash from 1 Gm. of Carmine with 1 Gm. of sodium cyanide, dissolve the fused mass in hydrochloric acid with the addition of a few drops of nitric acid, then dilute it with distilled water to 30 cc. and filter the solution. Separate portions of 10 cc. each of this solution yield no precipitate with hydrogen sulphide T.S. or with sulphuric acid (*tin, lead and soluble barium compounds*). Fuse the ash from 1 Gm. of Carmine with a mixture of 1 Gm. of sodium cyanide and 1 Gm. of potassium carbonate, extract the fused mass with boiling distilled water, filter, wash with hot distilled water and dissolve the residue in diluted hydrochloric acid; this solution does not become turbid on the addition of a few drops of sulphuric acid (*barium*).

"Preserve it in well-stoppered, amber-colored bottles." *N. F.*

It is used exclusively as a coloring agent.

Off. Prep.—Liquor Carmini, *N. F.*

CARUM. U. S. (Br.)

CARAWAY [Carawayseed, Caraway Seed]

"Caraway is the dried ripe fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*). Caraway contains not more than 3 per cent. of other fruits, seeds or foreign organic matter, and yields not more than 1.5 per cent. of acid-insoluble ash." *U. S.* "Caraway Fruit is the dried ripe fruit of Carum Carvi, *Linn.*" *Br.*

Carui Fructus, *Br.;* Caraway Fruit; Carvies, Cumin des Prés, Carvi, *Fr.;* Fructus Carvi, *P. G.;* Gemeiner Kümmel, Kümmel, Garbe, *G.*

The caraway plant is a biennial herb with a spindle-shaped, fleshy, whitish root from which arises, during the first year, a cluster of bi- to tripinnate leaves. During the second year there arises a slender stem bearing alternate, pinnate to bipinnate leaves, the terminal segments of which are very narrow and pointed. The inflorescence is a long-stalked, compound umbel bearing small white flowers with five minute calyx teeth, five ovate and notched petals, five stamens and a conical stylopod. The fruits are oblong; laterally compressed dark-brown cremocarps.

It is a native of Europe and Asia, growing wild in meadows and pastures, and cultivated in many places. The flowers appear in May and June, and the seeds which are not perfected until the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food in Northern Europe.

Caraway has been cultivated in Germany, Holland, Morocco, Spain, Norway, Russia, England and to a lesser extent in the northern part of the United States. The plant thrives well in clay soil containing some humus. The plants are mowed down when the oldest fruits are ripe, dried in the field or in the barn loft until they have lost most of their moisture, after which the fruits are thrashed out, cleaned and stored in bags. Most of the commercial supply used by this country comes from Holland in burlap bags.

Description and Physical Properties.—"*Unground Caraway.*—Usually in separated mericarps; curved, tapering towards both ends; up to 7 mm. in length and 2 mm. in diameter; externally dark brown with five yellow filiform ribs; odor and taste aromatic.

"*Structure.*—Mericarps nearly equilaterally pentagonal, with a fibro-vascular bundle in each rib; outer epidermis of tangentially-elongated, rather thick-walled cells, a middle layer of collapsed parenchyma bearing the oil tubes, usually six in number, sometimes one or more additional, and located between the ribs; an inner epidermis of broad parenchyma cells, more or less collapsed and which are coherent with the collapsed cells of the seed coat; endosperm of thick-walled parenchyma containing fixed oil and aleurone grains up to 0.010 mm. in diameter and in which are embedded rosette aggregates of calcium oxalate up to 0.004 mm. in diameter.

"*Powdered Caraway.*—Elements of identification are the outer epidermal cells characterized by a waviness and stripping of the cuticle; the cells of the endosperm containing aleurone grains with the embedded rosette aggregates; tracheæ; lignified fibers and fragments of the oil tubes." *U. S.*

"Mericarps usually separate; each from about four to six millimetres long and about one millimetre broad; brown with paler primary ridges; slightly curved, tapering towards each end, and glabrous. In transverse section, six vittæ in each mericarp. Odor and taste aromatic. Ash not more than 9 per cent." *Br.*

They have an agreeable aromatic odor, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. (See *Oleum Cari.*) The residue is insipid.

"Drawn caraway seeds," a term applied to such as have been recovered from the still residue after obtaining the volatile oil, are used to adulterate caraway; the exhausted "seeds" are much darker in color than are the genuine and are less odorous. (*P. J.*, 1896, 150.) While this is the principal form of adulteration, they may contain large amounts of stems, gravel, sand, dust, weed seeds and other impurities.

Uses.—Caraway is a pleasant stomachic and carminative, occasionally used in *flatulent colic,* and as an adjuvant or corrective of other medicines. The dose in substance is from fifteen to thirty grains (1–2 Gm.). An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is more employed. (See *Oleum Cari.*) Three and a half ounces of the oil of caraway caused violent vomiting and abdominal pain, with loss of consciousness, ending, however, in recovery. The urine contained both acetone and albumin. (*Cb. I. M.*, xxii, 1902.) In culinary operations the seeds are added to cakes, to which they communicate an agreeable flavor, while they stimulate the digestive organs.

Dose, fifteen to thirty grains (1–2 Gm.).

CARYOPHYLLUS. U. S. (Br.)

CLOVE Caryoph. [Cloves]

"Clove is the dried flower-buds of *Caryophyllus aromaticus* Linné (Fam. *Myrtaceæ*). Clove contains not more than 5 per cent. of its stems and not more than 1 per cent of other foreign organic matter, and yields not less than 15 per cent. of volatile ether-soluble extractive, not more than 10 per cent. of crude fiber, and not more than 0.75 per cent. of acid-insoluble ash." *U. S.* "Cloves are the dried flower-buds of Eugenia caryophyllata, *Thunb.*" *Br.*

Caryophyllum, *Br.;* Caryophylli Aromatici; Girofle, *Fr. Cod.;* Gérofle, Clous Aromatiques, Clous de Girofle, *Fr.;* Caryophylli, *P. G.;* Gewürznelken, Nägelein, *G.;* Garofani, *It.;* Clavo de especia, Clavillo, *Sp.;* Cravo da India, *Portug.;* Kruidnagel, *Dutch;* Kerunfel, *Arab.*

The clove-tree is a small tree inhabiting the Molucca Island and Southern Philippines. It has a pyramidal form, is evergreen, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth, grayish bark. The leaves are opposite, petiolate, about four inches in length by two in breadth, obovate-oblong, acuminate at both ends, entire, sinuate, with many parallel veins on each side of the midrib. They have a firm consistence and a shining green color, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odor.

The natural geographical range of the clove is extremely limited, being confined to the Molucca or, as they were one time called, Clove Islands. According to Flückiger, cloves were known in Western Europe as early as the sixth century, long before the discovery of the Moluccas by the Portuguese. After the conquest of the Molucca Islands by the Dutch, the monopolizing policy of that commercial people led them to extirpate the trees in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding their jealous vigilance, a French governor of the Islands of France and Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas and introducing them into the colonies under his control. Five years afterwards the clove-tree was introduced into Cayenne and the West Indies, in 1803 into Sumatra, and in 1818 into Zanzibar. At present the spice is cultivated both in the West and East Indies, in tropical Africa, and in Brazil. Approximately seven-eighths of the world's clove supply is grown in Zanzibar.

The unexpanded flower buds are the part of the plant employed under the ordinary name of cloves. They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are at first white, then become green, and then bright red, when they must be at once collected, which is done by hand picking, or by beating the trees with bamboos and catching the falling buds. In the Moluccas they are said to be sometimes immersed in boiling water and afterwards exposed to smoke and artificial heat before being spread out in the sun. In Zanzibar, Cayenne, and the West Indies they are dried simply by solar heat. The stems of the flowers also enter commerce. They possess the odor and taste of the cloves, but they are worth only about one-fifth the price of the cloves, as they are deficient in volatile oil. They are largely used as an adulterant in ground cloves, and are used in the manufacture of oil of cloves. In France they are generally known by the name of *griffes de girofle*.

Although it is stated that as early as 266 B.C., during the reign of the Han dynasty, the Chinese court officers were accustomed to hold cloves in their mouths before addressing the sovereign, that their breath might have an agreeable odor, the spice seems to have been first introduced into Europe in the fourth century, and became a great source of wealth to the enterprising merchants of mediæval Venice, who obtained it from the Arabians. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese, but was subsequently wrested from them by the Dutch, by whom it was long monopolized. (For detailed information as to method of cultivation, see *P. J.*, June, 1890.)

In commerce the varieties of cloves are known by the names of the localities of their growth, and so closely resemble one another as to be distinguished only by experts. The *Penang cloves* have been especially esteemed. The *Bencoolen cloves* from Sumatra are by many druggists deemed equal to them. The Amboyna and Molucca cloves are stated to be thicker, darker, heavier, more oily, and more highly aromatic than those cultivated elsewhere.

Description and Physical Properties.—"*Unground Clove.*—From 10 to 17.5 mm. in length, of a dark brown, or brownish-black color, consisting of a stem-like, solid, inferior ovary, obscurely 4-angled or somewhat compressed, terminated by 4 calyx teeth, and surmounted by a nearly globular head, consisting of 4 petals, which enclose numerous curved stamens and 1 style; odor strongly aromatic; taste pungent and aromatic, followed by slight numbness. Stems sub-cylindrical or 4-angled, attaining a length of 25 mm. and a diameter of 4 mm., either simple, branching, or distinctly jointed, and less aromatic than the flower-buds.

"*Powdered Clove.*—Dark brown; parenchyma fragments showing the large oil reservoirs, spiral tracheæ and a few rather thick-walled, spindle-shaped bast-fibers; calcium oxalate in rosette aggregates, from 0.010 to 0.015 mm. in diameter; pollen grains numerous, tetrahedral, from 0.015 to 0.020 mm. in diameter.

"Stone cells, irregular or polygonal, up to 0.070 mm. in diameter, with thick porous walls and large lumina frequently filled with a yellowish-brown amorphous substance, are few or absent (less than 5 per cent. of *stems*). Starch grains absent (*clove fruit or cereals*).

"**Assay.**—Proceed as directed under volatile ether-soluble extractive." *U. S.*

"About fifteen millimetres long, each consisting of a dark-brown, wrinkled, subcylindrical, somewhat angular calyx tube which tapers below and is surmounted by four thick, rigid, patent teeth, between which are four paler, imbricated petals enclosing numerous stamens and a single style. Odor strong, fragrant and spicy; taste very pungent and aromatic. Cloves emit oil when indented with the finger-nail. Ash not more than 7 per cent." *Br.*

Their color is externally deep brown, internally reddish; their odor strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and odor, they are inferior. Those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine. For monograph on the microscopical structure of cloves, clove stems and clove fruit see Winton and Moeller, "*The Microscopy of Vegetable Foods.*" Powdered cloves sometime contain an excess of clove stems, and may be adulterated with allspice, wheat middlings and powdered peas or beans. Occasionally clove stems alone are ground and sold as cloves. It is claimed that an enormous quantity of exhausted cloves are dishonestly marketed. The amount of volatile ether extract is the best criterion of the value of cloves.

The most important constituent is a volatile oil (see *Oleum Caryophylli*). Trommsdorff obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin, 130 of gum, 60 of resin, 280 of vegetable fiber, and 180 of water. Wm. L. Peabody (1895) found the percentage of tannin in cloves to range from 10 to 13 per cent., and that it has the same chemical composition as gallotannic acid. Lodibert afterwards discovered a green fixed oil, and a tasteless, white, resinous substance which crystallized in silky needles, soluble in ether and boiling alcohol, and exhibiting neither alkaline nor acid reaction. This substance was called by Bonastre *caryophyllin.* To obtain it, the ethereal extract of cloves is treated with water, and the white substance thrown down is separated by filtration, and treated repeatedly with ammonia to deprive it of impurities. Its formula as determined by Mylius (*B. Chem. G.,* 1873) is $C_{20}H_{32}O_2$. On oxidizing with fuming nitric acid it forms *caryophyllic acid,* $C_{20}H_{32}O_6$. Dumas discovered another crystalline principle, which, like caryophyllin, is soluble in alcohol and ether, but differs from that substance in becoming red when touched with nitric acid. Bonastre proposed for it the name of *eugenin.* (*J. P. C.,* xx, 565.) It has the formula $C_{10}H_{12}O_2$, and is isomeric with eugenol.

Water extracts the odor of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid if deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. For an account of the oil, see *Oleum Caryophylli.*

The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of ferric chloride, facts of some interest, as morphine gives the same reactions.

Uses.—Cloves are among the most stimulant of the aromatics, but, like others of this class, act less upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve *nausea* and *vomiting* correct *flatulence,* and excite *languid digestion;* but their chief use is to assist or modify the action of other medicines. They enter into several official preparations.

The French Codex directs a *tincture of cloves* to be prepared by digesting for ten days, and afterwards filtering, a mixture of three ounces of powdered cloves and sixteen of 80 per cent. alcohol.

Dose, in substance, from five to ten grains (0.32–0.65 Gm.).

CASCARA AMARGA. N. F.

CASCARA AMARGA. Cascar. Amarg.
[Honduras Bark]

"Cascara Amarga is the dried bark of an undetermined species of *Picramnia* (Fam. *Simarubaceæ*). Cascara Amarga contains not more than 2 per cent. of foreign organic matter." *N. F.*

About half a century ago there was brought into this country from Mexico a bark which had been used in that land as a tonic and alterative. This bark was identified by Doctor Vasey, of the Department of Agriculture, as coming from a species of *Picramnia.* No more accurate recognition of its source has since been made.

The genus *Picramnia* includes some 30 species, all of which are found in the American tropics and the West Indies Islands.

Description and Physical Properties.—"*Unground Cascara Amarga.*—In quills up to 500 cm. long and 3 cm. in diameter; bark up to 8 mm. thick, sometimes in broken, irregular, flattened or transversely curved pieces; externally yellowish brown, more or less covered with grayish lichens showing blackish apothecia, longitudinally fissured and roughened with cork layers, or with cork more or less removed and reddish brown; inner surface grayish brown to dark reddish brown, with irregular longitudinal striations and numerous minute transverse markings; internally dark brown with a light yellow zone beneath the cork and numerous yellowish groups of stone cells, the latter especially pronounced in the older bark; fracture short, hard and brittle. Odor faint; taste extremely bitter and persistent.

"*Structure.*—Outer bark of 25 or more rows of thick-walled, more or less lignified cork cells, many of which contain a yellowish to reddish coloring substance; phellogen layer distinct; middle bark with an outer zone of cortical parenchyma, a few isolated stone cells and an inner zone of a nearly continuous ring of stone cells, parenchyma, a few groups of fibers associated with crystal fibers; inner bark with groups of bast fibers associated with crystal fibers; sieve tissue, parenchyma containing starch, and numerous large groups of stone cells more or less transversed by medullary rays, the latter mostly 1 to 4 cells wide and arranged in regular rows.

"*Powdered Cascara Amarga.*—Light brown; numerous groups of bast fibers associated with crystal fibers, the latter with monoclinic prisms of calcium oxalate from 0.020 to 0.040 mm. in length; stone cells isolated or in groups, the individual cells up to 0.100 mm. in diameter; fragments of medullary ray tissue and parenchyma, the latter containing numerous irregular starch grains up to 0.025 mm. in length, rarely larger, occasionally 2- to 4-compound; occasional fragments of brown cork; few slightly lignified or non-lignified fibers." *U. S.*

Thompson (*A. J. P.,* 1884) separated from Honduras bark a yellow amorphous substance, which responded to the ordinary tests of alkaloidal nature such as: solubility in diluted acids, precipitation with Mayer's reagent, tannic acid, etc. He did not obtain either the base nor any salt in a crystalline form. He was satisfied, however, of its alkaloidal nature, and suggested the name *picramnine.* We know of no further chemical study of the drug.

Uses.—Honduras bark appears to have been used as a folk medicine in Mexico in chronic skin diseases, especially those of syphilitic origin. Doctor Atkinson (*T. G.*, 1881) reported a few cases of healing of syphilitic ulcers under the continued use of the remedy; his case histories, however, do not afford any convincing evidence that the healing process was materially hastened by the drug. Honduras bark is used to-day almost solely as an ingredient of the compound fluidextract of trifolium, and the syrup made from it.

Dose, fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Fluidextractum Trifolii Compositum, *N. F.;* Syrupus Trifolii Compositus, *N. F.*

CASCARA SAGRADA. U. S., Br.

CASCARA SAGRADA. Casc. Sagr. [Rhamnus Purshiana U. S. VIII]

" Cascara Sagrada is the dried bark of *Rhamnus Purshiana* De Candolle (Fam. *Rhamnaceæ*).

" NOTE.—Cascara Sagrada should be collected at least one year before being used for making medicinal preparations." *U. S.* " Cascara Sagrada is the dried bark of Rhamnus Purshianus, *D.C.*, collected at least one year before being used." *Br.*

Cortex Rhamni Purshiani, *P. G.;* Sacred Bark; Chittem Wood Bark, Dogwood bark, Coffee-berry bark, Pigeonberry bark, Bear-berry bark, Bitter bark and Yellow bark; Cascara Sagrada, *Sp.*

A number of species of Rhamnus have been described as growing in California, but according to the best authority there are only four species,—*R. alnifolia,* L'Her., *R. crocea,* Nutt., *R. Purshiana,* D.C., and *R. californica,* Esch. Of these species, *R. alnifolia* is too rare in the Cascara district to be important; while the spinescent twigs, the very thick oval or roundish leaves, and the small roundish red fruit of *R. crocea* make it so distinct that it cannot be confounded with a Cascara, whose bark, moreover, it does not resemble. On the other hand, *R. californica* appears to be very commonly confounded with the official species by collectors, and to have yielded some of the cascara sagrada bark of commerce. *R. californica* is rare in Northern California, but abundant in the countries lying south and southeasterly, while *R. Purshiana* is abundant in Northern California, but scarce in the south, so that any bark collected in Northern California is probably genuine. *R. californica* is chiefly distinguished from the official species by its leaves being thin, and, when not smooth, having a short close pubescence, and the primary veins of the under surface not nearly so numerous, straight, or fine as those of *R. Purshiana.* Rusby thinks that its leaves are especially distinguished by the channel of the midrib of *R. californica* being altogether absent, or shallow, or inconspicuous. Nevertheless the species so run into one another that competent botanists believe them identical.

The *Rhamnus Purshiana* is a small tree, attaining a height of twenty feet. Its leaves are rather thin, elliptic, for the most part briefly acutely pointed, finely serrated, at the base obtuse, somewhat pubescent beneath, from two to seven inches long and from one to three wide. The rather large flowers are in somewhat umbellate cymes; the sepals five; the minute cucullate petals bifid at the apex. The fruit is black, broadly obovoid, four lines long, three-lobed, and three-sided. The seeds are convex on the back, with a lateral raphe. It is found in California, Oregon, Washington and Southwest British Columbia. For details of manner of collecting the bark see an elaborate and illustrated article by Johnson and Hindman, *A. J. P.*, 1914, p. 387. Because of the rapid destruction of natural sources of the bark in the Western United States, experiments have been conducted by the Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., to cultivate it.

The *Rhamnus californica,* or *Californian buckthorn* or *California coffee-tree,* yields a bark which is of a dark brown color externally and bright yellow internally, having an intensely bitter taste, with a persistent nauseous aftertaste, and very little odor. It is said to be much more distinctly purgative than that of *R. crocea.*

It does not seem possible to distinguish with certainty between the barks of the two species by their macroscopic appearance. The bark of *R. Purshiana* is usually more red than is that of *R. californica,* but it may be of a distinctly gray color. The microscopic structure of the two barks is, however, different. The medullary rays in *R. Purshiana* are numerous, thin, for a long distance nearly parallel and straight and converge at their outer ends, run about three-quarters of the distance through the bark, and are one to four cells in width. In *R. californica* the medullary rays are much broader, much shorter, and are one to seven cells in width; further, they are crooked and not parallel throughout their course. Again, the zone of resin spaces is much broader in *R. californica,* and the spaces themselves much larger and more numerous than in the official species. For further details and elaborations, see papers by H. H. Rusby, *Proc. A. Ph. A.*, 1890, and by Gathercoal, *J. A. Ph. A.*, 1915, p. 15. According to L. E. Sayre (*A. J. P.*, March, 1897), the powder of the barks can be distinguished by paying attention to the fact that *R. Frangula* contains no stone cells, while in *R. californica* and *R. Purshiana* such cells are abundant, occurring in large, irregular groups below the cork and usually outside the region of the bast. *R. Purshiana* may also be distinguished from *R. californica* by color tests. After several days' maceration in dilute alcohol the powder of *R. Purshiana* appears of an orange-yellow color, *R. californica* of a purplish color; or if 0.2 Gm. of the powdered bark be placed in a small test tube, and there be added 2 cc. of potassium hydroxide test solution, *R. californica* will give a blood-red and *R. Purshiana* an orange-red color.

The bark of the *Rhamnus crocea,* the so-called *California mountain holly,* occurs in slightly curved pieces, externally of a dark brown color, internally of a characteristic red delicately streaked with numerous white veins. The odor is somewhat aromatic, the taste warming and not unpleasantly bitter. It is affirmed to be a tonic and mild laxative.

Description and Physical Properties.—"*Unground Cascara Sagrada.*—Usually in flattened or transversely curved pieces, occasionally in quills; bark from 1 to 5 mm. in thickness; outer surface dark brown or brownish-red, longitudinally ridged, with grayish or whitish lichen patches, sometimes with numerous lenticels and occasionally with moss; inner surface longitudinally striate, light yellow to dark reddish-brown or dark brown in old matured bark; fracture short with projections of bast-bundles in the inner bark; odor distinct; taste bitter and slightly acrid.

"*Structure.*—Cork yellowish-brown to reddish-brown, of 10 or more rows of small cells; stone cells in yellowish, tangentially elongated groups of 20 to 50 cells; medullary rays 1 to 4 cells wide, 15 to 25 cells deep, frequently diagonal or curved forming converging groups; bast-fibers in small bundles surrounded by crystal fibers and located between the medullary rays; parenchyma with brown walls and containing starch grains or calcium oxalate.

"*Powdered Cascara Sagrada.*—Light brown to olive-brown; consisting of broken bast-bundles with the accompanying crystal fibers containing monoclinic prisms of calcium oxalate; stone cells more or less adhering, with thick, finely lamellated and porous walls; fragments of reddish-brown cork; masses of parenchyma and medullary ray cells, colored red upon the addition of a solution of an alkali; starch grains spheroidal, from 0.003 to 0.008 mm. in diameter; calcium oxalate in monoclinic prisms or rosette aggregates from 0.006 to 0.020 mm. in diameter.

"Add 0.1 Gm. of powdered Cascara Sagrada to 10 cc. of hot water, shake the mixture occasionally until cold, filter, and add sufficient water to make the filtrate measure 10 cc.: this filtrate, on the addition of 10 cc. of ammonia T.S., is colored an orange-yellow. Macerate 0.1 Gm. of powdered Cascara Sagrada with 10 drops of alcohol, boil the mixture with 10 cc. of water, cool, filter, and shake the filtrate with 10 cc. of ether: a yellow ethereal solution separates. Shake 3 cc. of this ethereal solution with 3 cc. of ammonia T.S.: the separated ammoniacal solution on diluting with 20 cc. of water retains a distinct, yellowish-red color." *U. S.*

"In quilled, channeled, or nearly flat pieces from one to two millimetres thick, but varying in length and width. Cork nearly smooth, dark purplish-brown, marked with transversely elongated lenticels, but usually more or less covered with patches of silvery-grey lichen. Inner surface reddish-brown, with faint transverse corrugations and longitudinal striations. Fracture short, but near the inner surface somewhat fibrous. In transverse section, scattered groups of sclerenchymatous cells in both cortex and bast; the parenchymatous cells contain a yellow substance which is colored violet by *solution of sodium hydroxide.* Odor characteristic but not powerful; taste nauseous, bitter and persistent." *Br.*

For articles illustrating the pharmacognosy of Cascara bark see Kraemer, *A. J. P.,* 1912, p. 385; Miller, *J. A. Ph. A.,* 1912, p. 1207; and Farwell, *J. A. Ph. A.,* 1914, p. 649.

Constituents.—A. B. Prescott in the year 1879 found in it a very bitter brown resin (which is colored a vivid purple-red by potassium hydroxide); a red resin; a light yellow resin; a neutral crystallizable substance; a volatile oil and vegetable acids. H. F. Meier and J. LeRoy Webber reported the presence of a ferment, to which they attributed the unpleasant results attending the administration of "fresh bark"; "seasoned bark"—*i.e.,* such as has been kept a year or two—owes its valuable properties as a laxative, *free from griping,* to the fact that the ferment has exhausted itself; the laxative properties, they state, reside in the resins, and the tonic effects are due to the crystalline principle. (*A. J. P.,* 1888, 91.) Schwabe (*A. Pharm.,* ccxxvi, 569) found emodin. Dohme and Engelhardt (*Proc. A. Ph. A.,* 1897, 193) have shown the analogy of cascara sagrada with *Rhamnus Frangula* by obtaining a glucoside to which they give the name of *purshianin.* This decomposes, yielding emodin and a dextro-rotatory non-fermentable sugar, while the frangulin of buckthorn yields emodin and rhamnose as the sugar. Purshianin forms brown-red needles, melting at 237° C. Dohme and Engelhardt failed to obtain in a pure form (*Proc. A. Ph. A.,* 1898, 340) the bitter principle of cascara sagrada. Le Prince (*C. R. A. S.,* 1892, 286) claimed to have obtained the active principle of cascara bark in a crystalline form, which he named *cascarine;* his results are doubted by Jowett who believes that cascarine and purshianin are impure forms of emodin. Jowett (*Proc. A. Ph. A.,* 1904, 288) in an exhaustive paper concludes that the active principle of cascara is contained in that portion of an alcoholic extract which is soluble in water and precipitable by lead subacetate and in that portion of the regenerated lead subacetate precipitate which is soluble in ethyl acetate. Pietsch reported a glucoside, *peristaltin,* having the composition $C_{14}H_{18}O_8$. (*Th. M.,* 1910, No. 1, p. 35.)

Uses.—Cascara sagrada belongs to the group of vegetable cathartics whose activity depends upon the presence of one or more oxides of methylanthraquinone (see *Rheum*). In cascara the active principle appears to be emodin, which is trioxymethylanthraquinone, and which appears also to be the purgative principle of aloes.

The action of this principle is chiefly to excite peristalsis in the colon, although after large doses there is probably also some effect upon the upper bowel. As the action is chiefly upon the lower intestine it is not to be recommended as a laxative where it is desired to clean out the bowel, but in the treatment of *chronic constipation* it acts very favorably. It often appears to restore tone to the relaxed bowel and in this way produce a permanent beneficial effect. McGuigan (*J. A. M. A.*, 1921, lxxvi, 513) says that large doses produce an inflammatory condition of the bowel and that the drug should, therefore, never be used to produce active purgation. The bark itself is rarely used, either the extract or fluidextract being eligible preparations.

The addition of belladonna to overcome any tendency to gripe is an advantage. Ordinarily a single dose is given at bedtime but in some cases better results are obtained by exhibiting smaller doses after meals.

Dose, ten to thirty grains (0.6–2.0 Gm.).

CASCARILLA. N. F., Br.

CASCARILLA

" Cascarilla is the dried bark of Croton Eluteria, *J. J. Benn.*" *Br.*

Cascarillæ Cortex, *Br.* (1885), Cascarilla Bark, Sweet Bark, Sweetwood Bark; Cascarille officinale, *Fr. Cod.;* Cortex Eluteriæ, Cortex Thuris; Chacrille, Ecorce éleuthérienne Cascarille, *Fr.;* Cortex Cascarillæ, *P. G.;* Cascarillrinde; Cascarilla, Kaskarillrinde, *G.;* Cascarilla, Cascariglia, *It.;* Chacarilla, Quina aromatica, *Sp.*

Croton Eluteria is a shrub or a small tree with a stem from four to eight inches in diameter. The stem is straight, and marked at intervals with white or grayish stains. The leaves are petiolate, often somewhat cordate at the base, obtusely acuminate, pale or grayish-green above, and densely covered beneath with shining silvery scales, appearing white at a distance. They are smaller and narrower in the plants of arborescent growth. The flowers, which have a delicious odor, are monœcious, small, white, petiolate, and closely set in simple terminal or axillary spikes. The shrub is a native of the Bahamas, scarce at present in the island of New Providence, but still abundant in Andros, Long, and Eleutheria islands, from the latter of which is derived its botanical title. Daniell calls the plant *sweetwood.* The name of *sea-side balsam* belongs to another species, *C. balsamiferum* Linnæus, which grows in the Bahamas and other West India islands, and owes its name to the exudation of a balsamic juice from its young branches when wounded.

Under the name of " cascarilla," also " *Quina morada,*" the bark of the *Pogonopus febrifugus* is said to be used in the Argentine Republic as a substitute for cinchona bark. There has been separated from it a blue fluorescent substance, *moradin,* and an alkaloid, *moradeine.* (*P. J.*, xx, 854.)

Copalchi bark has been mistaken not only for cascarilla, but also for a variety of cinchona. Two kinds were noticed: one, in small slender quills, of an ash color, bearing some resemblance to a variety of pale cinchona, but having the flavor of cascarilla, and burning with a similar odor; the other in larger quills, with a thick cork-like epidermis, very bitter, and yielding an aromatic odor when burnt. The former is the product of *Croton Pseudochina,* Schlechtendal (*C. niveus* Jacquin); the latter is of unknown origin, but conjecturally referred to *C. suberosus.* J. E. Howard states that the quilled copalchi bark contains a bitter alkaloid, soluble in ether, and precipitable as a white hydroxide from its acid solution. (*P. J.*, xiv, 319.) Copalchi bark is an aromatic tonic, employed in Mexico in intermittents, and capable of useful application in all cases requiring a mild aromatic bitter.

Croton Cascarilla Bennett, known in the West Indies as *wild rosemary,* was at one time said to furnish the cascarilla of commerce. The bark is also substituted by the barks of *Croton glabellus* L. and *C. lucidus* L. of the Bahamas and which were formerly designated as the " mother plants " of Cascarilla. They are not aromatic but astringent and slightly bitter. They are also distinguished by the presence of stone cells which are wanting in true Cascarilla. (See *U. S. D.*, 19th ed.)

Cascarilla is brought to this market from the West Indies, and chiefly Nassau, on the island of New Providence. It comes in bags or casks. We have observed it in commerce in two forms, so distinct as to merit the titles of varieties. In one, the bark is in rolled pieces of every size, from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark brown surface, while the inner surface has a chocolate color, and the fracture is a reddish-brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces, not more than an inch or two in length, very thin, without the white cork, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fiber attached to their inner surface, and appearing precisely as if shaved by a knife from the stem or branches. Whether these two varieties are derived from distinct species, or differ only because of the mode of collection, it is difficult to determine. A. W. Southall describes a bark believed to belong to the genus *Croton,* and obtained from Colombia in *P. J.,* 1894, 574.

According to the Br. it is: "in quills usually from three to ten centimetres in length and from four to twelve millimetres in diameter, or in small curved pieces. Cork greyish-white, easily detached, and often more or less completely removed disclosing a dull brown cortex. Both cork and cortex frequently marked with numerous longitudinal and transverse cracks. Fracture short, the fractured surface exhibiting under a lens a dark reddish-brown bast traversed by numerous, thin, whitish medullary rays. In transverse section cork cells with strongly thickened outer walls, but thin inner walls, in which minute crystals of calcium oxalate are embedded; both cortex and bast free from sclerenchymatous cells. Aromatic odor, especially when burned; taste aromatic and bitter. Ash not more than 11 per cent." *Br.*

Trommsdorff found in the bark 1.6 per cent. of a fixed oil. It is of a greenish-yellow color, has a penetrating odor analogous to that of the bark, and is of the sp. gr. 0.938. G. Feudler (*A. Pharm.,* 1900, p. 671) finds the oil to contain about 2 per cent. of free acid, which consists of a liquid acid, $C_{11}H_{20}O_2$, to which the name of *cascarillic acid* was given, and a solid portion made up of a mixture of palmitic and stearic acids. The oil contains 0.3 per cent. of eugenol, a terpene differing from pinene, cymene, possibly some l-limonene, two sesquiterpenes and an alcohol, $C_{15}H_{23}OH$. Duval in 1845 found in cascarilla a crystalline principle which he called *cascarillin.* This he obtained by treating infusion of the bark with lead acetate; he separated the lead by hydrogen sulphide, filtered, evaporated with the addition of animal charcoal, filtered again, evaporated at a low temperature to a syrupy consistence, and having allowed the semi-liquid substance thus obtained to harden by cooling, purified it by twice successively treating it, first with a little cool alcohol, to separate the coloring and fatty matters, and afterwards with boiling alcohol and animal chacoal. The last alcoholic solution was allowed to evaporate spontaneously. Thus obtained, cascarillin is white, crystalline, inodorous, bitter, very slightly soluble in water, soluble in alcohol and ether. It is not volatile nor a glucoside. Naylor and Littlefield re-investigated Duval's cascarillin and find its melting point to be 203.5° C., and give it the formula $C_{16}H_{24}O_5$. (*Y. B. P.,* 1896, 301.) P. E. Alessandri obtained what he regarded as an alkaloid, by mixing powdered cascarilla with sufficient 3 per cent. aqueous solution of oxalic acid to cover it, shaking the mixture, and heating it to 60° C., then allowing it to cool, expressing the mixture and saturating the filtered liquor with ammonia, then evaporating at a low temperature to two-thirds of its bulk, allowing it to cool, and separating any deposit. The clear liquid is then shaken with ether; this takes up the cascarilline, which may be obtained through evaporation of the ethereal liquid. (*P. J.,* 1882, 993.) R. A. Cripps was unable to obtain the alkaloid by Alessandri's method, and suggests that the bitterness of the so-called cascarilline might be due to adherent resin. (*P. J.,* 1886, 1103.) Either alcohol or water will partially extract the active matters of cascarilla; W. A. H. Naylor has found betaine in cascarilla. (*P. J.,* 1898, 279.)

Uses.—This bark is aromatic and tonic. It was known in Germany as early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against that febrifuge in the treatment of *remittent* and *intermittent fevers.* It has, however, lost its reputation, and is now employed only where a pleasant and gently stimulant tonic is desirable, as in *atonic dyspepsia,* and other cases of debility of the stomach or bowels, especially in combination with the more powerful bitters. It may be given in powder or in infusion. In consequence of its pleasant odor when burned, some smokers mix it in a small quantity with their tobacco; but it is said to occasion vertigo and intoxication.

Dose, twenty to thirty grains (1.3–2.0 Gm.).

Off. Prep.—Infusum Cascarillæ, *Br.;* Tinctura Cascarillæ, *Br.*

CASSIA FISTULA. N. F. (Br.)

CASSIA FISTULA Cass. Fist. [Purging Cassia]

"Cassia Fistula is the dried fruit of *Cathartocarpus Fistula* (Linné) Persoon (Fam. *Leguminosæ*). Cassia Fistula contains not more than 2 per cent. of foreign organic matter." *N. F.*

"Cassia Pods are the ripe fruits of Cassia Fistula, *Linn.*" *Br.*

Cassia Fructus, *Br.;* Cassia Pods; Pudding-stick (or pipe); Fructus Cassiæ Fistulæ; Casse Officinale, Casse en bâtons, Pulpe de Casse, Casse, Mondée Casse, *Fr.;* Röhrenkassie, Purgirkassie, Fistelkassie, *G.;* Cassia, *It.;* Cana Fistula, *Sp.*

Cassia Fistula L. (*Cathartocarpus Fistula* (L.) Persoon is a large tree attaining a height of about 15 m. with a trunk of hard, heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth, ash-colored bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are petiolate, ovate, pointed, undulated, smooth and of a pale green color. The flowers are large, of a golden yellow color, and arranged in long, pendent, axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous loments, which when agitated by the wind strike against each other and produce a sound that may be heard at a distance. This species of Cassia is a native of India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in insular and continental India, Cochin China, Egypt, Nubia, the West Indies, and the warmer parts of the continent of America. Under the name of *Golden Shower* it is known as an ornamental shade tree in all tropical countries. The fruit is the official part of the plant. Most of the drug used in the United States is imported from the West Indies, and from South America.

Description and Physical Properties.—"*Unground Cassia Fistula.*—Cylindrical, from 25 to 50 cm. long, about 20 mm. in diameter, smooth, chestnut-brown in color, on one side a longitudinal groove and on the other a smooth line or slight ridge, indicating the sutures; indehiscent, the cavity divided transversely into numerous compartments, each containing a reddish brown, glossy, flattish ovoid seed embedded in a blackish brown sweet pulp. Odor resembling that of prunes." *N. F.*

It is described in the Br. as: "Long, narrow, cylindrical, shortly stalked fruits about thirty-five to fifty centimetres in length, and fifteen to twenty-five millimetres in diameter. Pericarp nearly smooth, dark chocolate-brown or nearly black, thin and hard. Internally divided by thin, transverse dissepiments into numerous compartments, each of which contains a smooth, oval, reddish-brown seed surrounded by a nearly black, sweet pulp." *Br.*

The pods of other species of cassia are sometimes substituted for the official. The pods of the *Cassia Braziliana* Lam. (*C. Grandis* L.), sometimes called *horse cassia,* are larger than those of the *Cassia fistula,* being about 4 cm. (1½ inches) in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but in other respects seemed to have the properties of the official purging cassia. The fruit of the *C. Moschata* H. B. K. is smaller and narrower than the official variety, from 30 to 50 cm. in length and about 1.5 cm. in diameter; the pulp is of a lighter color and with a musk-like odor.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures and removing the pulp with a spatula.

Dose, one to four drachms (4–15 Gm.).

Off. Prep.—Confectio Sennæ, *N. F.*

CASSIÆ PULPA. Br.

CASSIA PULP

"Exhaust crushed Cassia Pods by percolation with Distilled Water; strain; evaporate on a water bath to the consistence of a soft extract." *Br.*

Cassia pulp has a slight odor, and a sweet, mucilaginous taste. According to Henry it contains sugar, gum, coloring matter, and a tannin-like substance; while Haensel obtained from it by steam distillation a dark yellow volatile oil, also butyric acid (*Ph. Cb.,* 41). It also apparently contains some anthraquinone derivative, the exact nature of which has not been determined.

Uses.—Cassia pulp is laxative, and may be advantageously given in small doses in cases of *habitual costiveness.* In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is rarely prescribed, except as an ingredient in the confection of senna, which is a pleasant and useful laxative preparation.

Dose, of the pulp as a laxative, one or two drachms (3.9 or 7.7 Gm.), as a purge one or two ounces (31–62 Gm.).

Off. Prep.—Confectio Sennæ, *Br.*

CASTANEA. N. F.

CASTANEA Castan. [Chestnut Leaves]

"Castanea consists of the dried leaves of *Castanea dentata* (Marshall) Borkhausen (Fam. *Fagaceæ*). Castanea contains not more than 5 per cent. of its stems or other foreign organic matter." *N. F.*

Feuilles de chataignier, *Fr.;* Kastanienblätter, *G.;* Castagna, *It.*

Of the few species included in the genus *Castanea,* two are natives of North America. Of these *C. dentata* has been considered by many botanists as identical with *C. sativa* Mill. (*C. vesca* Gaertn.), of Europe, and was described by Michaux as a variety of that species under the name of *americana.* Botanists at present, however, generally consider the two species as distinct.

Castanea dentata is a large, spreading, deciduous tree with deeply fissured bark, smooth, simple, alternate, oblong-lanceolate leaves with serrate margins. Its staminate flowers are crowded on lower aments while its pistillate flowers appear as spherical structures at the base of the upper aments. Its fruit is a spiny bur containing 1 to 5, usually 2 or 3 nuts. Chestnut leaves are gathered in autumn and carefully dried.

Description and Physical Properties.—"*Unground Castanea.*—Blade entire or slightly broken and usually folded or matted together; about 15 to 25 cm. long and about 5 cm. wide, oblong-lanceolate, apex attenuate, acute at the base, coarsely and sharply serrate with ascending, attenuate teeth, nearly smooth, coriaceous in texture, the upper surface dark green, the lower light green; distinctly pinnately veined, the veins of the first order diverging at an angle of about 60 degrees, each terminating in one of the teeth; petiole stout, about 12 mm. long. Odor slight; taste astringent.

"*Powdered Castanea.*—Few non-glandular hairs from 0.100 to 0.500 mm. long, occasionally up to 1.500 mm. in length, nearly smooth, thick-walled, distinctly yellow, occasionally in groups of 3 to 8 and spreading from the base; numerous calcium oxalate crystals in rosettes or in monoclinic prisms from 0.010 to 0.050 mm. in diameter occasionally in crystal fibers; parenchyma cells containing irregular yellowish brown tannin masses which are colored blue with ammonioferric alum T.S." *N. F.*

Castanea pumila (L.) Mill., *Chinquapin* of the Southern United States, is a bush or small tree usually eight or ten feet in height, but in the Gulf States reaches sometimes thirty feet. The oblong, acute, mucronately serrated leaves are readily distinguished from those of the ordinary chestnut by being whitish and downy underneath. The tree produces a small, edible nut. The bark has been used as an astringent tonic. (For analysis, see *A. J. P.,* 1899.)

Uses.—Chestnut leaves were recommended a half a century ago in the treatment of *whooping-cough* and the superstition still survives to a certain extent. There is, however, no sufficient reason to believe them to possess any therapeutic value except that of a mild astringent which is due to their tannic acid.

Dose, one drachm (4 Gm.).

Off. Prep.—Fluidextractum Castaneæ, *N. F.*

CATARIA. N. F.

CATNEP Catar. [Catmint]

"Catnep consists of the dried leaves and flowering tops of *Nepeta Cataria* Linné (Fam. *Labiatæ*). Catnep contains not more than 5 per cent. of its stems over 4 mm. in diameter or other foreign organic matter." *N. F.*

Catairs, *Fr.*; Katzenmünze, *G.*; Cattara, *It.*; Gatera, *Sp.*

Catnep is a perennial labiate plant which is common near dwellings in the United States, but is indigenous to Europe. Most of the drug is grown in the United States. It is called *catnep* on account of the fondness which cats show for it either in the fresh or the dried condition. The active constituents are volatile oil, and tannin of the kind which produces a greenish color with the salts of iron.

Description and Physical Properties.—"*Unground Catnep.*—Tops, from 10 to 20 cm. long, much branched, or crushed and broken; stems quadrangular, downy, up to 4 mm. in diameter; leaves opposite, the larger, petiolate, from 2 to 7 cm. long, ovate or oblong, rounded or heart-shaped at the base, pointed at the apex, pale gray-green, soft-hairy above, downy beneath, margin deeply crenate; floral leaves small, bract-like; flowers small, in dense, interrupted spikes; calyx hairy, tubular, curved obliquely and sub-equally 5-toothed; corolla whitish, dotted with purple, throat dilated, limb bilabiate, the upper lip erect and two cleft, the lower spreading and three cleft, the middle lobe largest, crenulate; stamens two pairs ascending under the upper lip, lower pair shorter. Odor faintly aromatic and mint-like; taste bitter, pungent and aromatic.

"*Powdered Catnep.*—Light green or grayish green; numerous fragments of parenchyma, the palisade tissue containing green plastids; non-glandular hairs numerous, 1- to 5-celled, tapering, more or less broken, the basal cells up to 0.050 mm. in diameter; glandular hairs with 1-celled stalk and many-celled secreting head, the latter up to 0.070 mm. in diameter; tracheæ with spiral, reticulate, annular or simple pore markings; stomata broadly elliptical up to 0.030 mm. in diameter; collenchyma and lignified wood fiber bundles, few.

"Preserve Catnep in air-tight containers." *N. F.*

Uses.—Catnep has no therapeutic virtues other than that of a mild aromatic. Like other substances of this class it is used, domestically, in the form of a hot decoction as a sudorific in *colds* and *febrile* complaints, and in painful or delayed menses. Chewing the leaves is reputed to relieve *toothache.*

Dose, one to two drachms (4–8 Gm.).

Off. Prep.—Fluidextractum Catariæ, *N. F.;* Elixir Catariæ et Foeniculi, *N. F.*

CATECHU NIGRUM. Br.

BLACK CATECHU

"Black Catechu is an extract prepared from the wood of Acacia Catechu, *Willd.*" *Br.*

Terra japonica, Cutch, Cachou de Pegu, *Fr. Cod.;* Pegu Katechu, *G.;* Caticu, Catto, *It.;* Catecu, *Sp.;* Cutt, *Hindostani.*

Acacia Catechu is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. Its leaves are bipinnate; the flowers are yellow and arranged on elongated racemes. The fruit is a brown, flattened, legume containing several brown, shiny seeds. This species of Acacia is a native of India and Burma, growing abundantly in various provinces of Hindostan, and in the Burmese Empire. It is also common in Eastern Africa where it is valued for its wood; but no extract appears to be made from it. Pereira says that it is common in Jamaica.

This drug was long known before its source was discovered. It was at first called *Terra japonica,* under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the Materia Medica to be an extract of the *betel nut.* Its true origin was made known by Kerr, assistant surgeon of the civil hospital in Bengal. In the preparation of cutch the exterior white wood is rejected, the brownish heart-wood after being cut into chips is boiled in water, in unglazed earthen vessels, until all the soluble matter is dissolved. The decoction thus obtained is strained and then boiled, until it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account subsequently given by Royle, of the preparation of the extract in Northern India, is essentially the same, but is completed by the pouring of the extract into quadrangular earthen moulds in which it hardens in mases of 40 or 50 pounds. These are afterwards broken up into fragments, in which form it appears in commerce. It is said that the unripe fruit and leaves are also sometimes submitted to decoction. Three colors of catechu are prepared; the light red or red, which is considered best and is especially employed in Burmah and India to chew with the betel nut; the dark red and black, which are made especially for European and American markets, and which are apt to suffer adulteration *en route* in China.

The name "catechu" in the native language signifies the juice of a tree, and appears to have been applied to astringent extracts obtained from various plants. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepaul through Calcutta, from Canara through Bombay, and from the Burmese dominions. It is frequently called *cutch* by the English traders, a name derived from the Hindostanee word *cutt.*

Catechu is inodorous, with an astringent and bitter taste, followed by a sense of sweetness. It is brittle, and breaks with a fracture which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark color, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities.

Black catechu is described in the Br. Pharm., 1914, as follows: "In irregular masses of a dark brown color, brittle, having a porous, glossy, somewhat conchoidal fracture. Partially soluble in cold *water,* almost entirely soluble in boiling *water.* Not less than 60 per cent. is soluble in *alcohol* (90 per cent.). No odor; taste sweetish, astringent. Its dilute aqueous solution gives a dark green color with *T. Sol. of ferric chloride,* changing to purple when made slightly alkaline with *solution of sodium hydroxide.* Ash not more than 5 per cent.; ash of the powder not more than 8 per cent. In India, in the Eastern, and in the North American Divisions of the Empire, Black Catechu may be employed in making the official preparations for which Catechu is directed to be used." *Br.*

Its most important constituent is a tannin, called *catechutannic acid,* of which it contains from 25 to 50 per cent. In addition it contains from 20 to 30 per cent. of gum, smaller amounts of a principle allied to the catechin of gambir and known as *acacatechin* and a coloring matter known as *catechu red,* $C_{36}H_{34}O_{15}$, which is evidently the first anhydride of catechin. The catechu tannic acid is of the variety which precipitates iron of a greenish-black color, and differs from most of the other varieties in not yielding grape sugar when digested with diluted sulphuric acid. It is not, therefore, a glucoside. It precipitates gelatin, but not tartar emetic (Kane), and is not, like the tannic acid of galls, converted into gallic acid by the access of the air. Catechu is almost wholly soluble in a large quantity of water, to which it imparts a brown color. The extractive, catechuic acid, is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves it much more readily than cold, and deposits it of a reddish-brown color upon cooling. Both principles are readily dissolved by alcohol or proof spirit, and also by ether.

A. Jossart (*J. P. A.,* 1881, 41) examined a catechu which was adulterated with from 60 to 65 per cent. of ferrous carbonate. For methods of assaying catechu and gambir, see Trimble's *The Tannins;* also *Ph. Rev.,* 1897, 27. (See also *Gambir,* and *U. S. D.,* 19th ed., p. 1436.)

Catechu is used for the same purposes and in the same proportions as *Gambir.*

Dose, five to fifteen grains (0.3–1.0 Gm.).

Off. Prep.—Pulvis Catechu Compositus, *Br.;* Tinctura Catechu, *Br.;* Trochiscus Catechu, *Br.*

CAULOPHYLLUM. N. F.

CAULOPHYLLUM Cauloph. [Pappoose Root, Squaw Root, Blue Cohosh]

"Caulophyllum consists of the dried rhizome and roots of *Caulophyllum thalictroides* (Linné) Michaux (Fam. *Berberidaceæ*). Caulophyllum contains not more than 3 per cent. of foreign organic matter and yields not than 4 per cent. of acid-insoluble ash." *N. F.*

This is an indigenous, perennial, herbaceous plant, with matted, knotty rhizomes, from which rises a single smooth stem, about two feet high which terminates in a panicle of greenish-yellow flowers.

Description and Physical Properties.—"*Unground Caulophyllum.*—Rhizome of horizontal growth, from 7 to 25 cm. long and from 5 to 15 mm. thick, much branched, slightly compressed from above, bearing large, cup-shaped stem scars on the upper surface and underneath roots which frequently conceal the rhizome; roots in a tangled or matted mass, long, curved, tortuous, thin, tough, profusely branched, the branches of about equal size and diverging at angles of about 45 degrees; both rhizome and root of a grayish or yellowish gray color; fracture tough and woody. Odorless but sternutatory; taste bitter-sweet and acrid.

"*Powdered Caulophyllum.*—Light brown; starch grains numerous, spherical in outline, mostly simple, up to 0.016 mm. in diameter; fragments of cork with cells about 0.050 mm. in diameter and having yellowish brown walls; tracheæ up to 0.050 mm. wide and with bordered pores; wood fibers and tracheids with heavily lignified walls: fragments of parenchyma tissue with many of the cells containing starch grains." *N. F.*

Caulophyllum contains a glucosidal saponin to which J. U. Lloyd has applied the name of *leontin.* (See *Drugs and Med. of North Amer.*, vol. 2, p. 152.) It also contains an alkaloid, *caulophylline,* which according to Power and Salway (*Tr. Chem. Soc.*, 1913, ciii) is *methylcytisine.* It has not been investigated physiologically. The fruit has been analyzed by Stockton and Elbridge (*Chem. News,* 1908, p. 190).

Uses.—As suggested by its popular name, caulophyllum was used by the American Indians to facilitate *child-birth.* As it was administered, however, two or three weeks previous to labor this evidence of its value does not seem very conclusive. However, the practice was brought to the attention of the medical profession by Peter Smith in 1813 and many physicians of the past generation attributed to it marked oxytocic properties. It has been used in the treatment of various uterine disorders such as *amenorrhea, dysmenorrhea, menorrhagia,* etc., implying somewhat contradictory properties on the part of the drug. Thus, it has been variously claimed that it is capable of producing abortion and that it will arrest threatened abortion. Pilcher (*J. A. M. A.*, 1916, lxvii, 490) found that it has a marked stimulating effect on the uterine muscle but did not believe this would occur under clinical use. It was also employed by the eclectics in hosts of other diseases such as *chronic rheumatism, bronchitis, intestinal colic* and *hysteria.* Its practical value is certainly open to doubt.

The *dose* of the crude drug, which is sometimes employed in the form of decoction, is ten to thirty grains (0.6–2 Gm.).

Off. Prep.—Fluidextractum Caulophylli, *N. F.;* Elixir Aletridis Compositum, *N. F.;* Elixir Heloniadis Compositum, *N. F.*

CENTAURIUM. N. F.

CENTAURY Centaur.

"Centaury is the dried flowering herb of *Erythræa Centaurium* (Linné) Persoon (Fam. *Gentianaceæ*). Centaury contains not more than 3 per cent. of foreign organic matter." *N. F.*

Common European Centaury; Petite Centaurée, *Fr. Cod.*; Herba Centaurii, *P. G.;* Tausendgüldenkraut, *G.*

The centaury is a small annual herb with an upright branching stem which bears a few small alternate leaves, most of the leaves being arranged in a basal tuft. The flowers which are of a purplish rose color are borne in flat-topped clustered cymes. The plant is a native of Europe but has been naturalized in the United States, especially along the shores of Lakes Ontario and Michigan. For description of "American Centaury" see *Sabbatia,* Part II. *E. acaulis,* which grows in great abundance in the territory of French Algiers bordering on the Sahara, yields a root which, under the name of *rejagnou,* is employed by the natives for dyeing yellow.

Description and Physical Properties.—"*Unground Centaury.*—Glabrous, from 1.5 to 5 cm. in length, much branched from the base, but little branched, if at all, from above; stems slender, sharply angled or narrowly winged, sparsely leafy; leaves opposite, entire, mostly three-nerved, sessile, those at the base obovate and obtuse, from 2 to 5 cm. long, their bases norrowed and petiole-like, those above gradually oval, ovate or even lancelinear, acute; flowers in a terminal and at length compound cyme, rose-colored; calyx from 5 to 7 mm. long, deeply five-parted, the tube short sharply angled, lobes linear-attenuate with a sharp midrib; corolla tube nearly twice the length of the calyx, slender, the limb from 10 to 15 mm. wide, its lobes broadly oblong or oval; stamens five, exserted, bright-yellow, their anthers twisted when old; pistil two-carpelled. Odor faint but characteristic, taste persistently bitter.

"*Powdered Centaury.*—Light brown to darker yellow-orange; with numerous fragments of lignified mechanical tissue composed of wood fibers, wood parenchyma and tracheæ, the latter with bordered pores, annular or spiral markings; leaf tissue containing rosettes or prisms of calcium oxalate up to 0.012 mm. in length; leaf epidermis of cells with irregular vertical walls and surface walls frequently striated; non-glandular hairs from lower margins of leaves; few, simple, elliptical stomata up to 0.035 mm. long; chlorophyll containing parenchyma; epidermal tissue of petals and calyx with papillated cells; abundant pollen grains, 0.025 to 0.030 mm. in diameter, spherical, smooth, with three pores; brownish fragments of reticulated seed-coat composed of small stone cells; abundant pith and cortical parenchyma." *N. F.*

This plant yields a peculiar colorless crystalline non-nitrogenous substance *erythrocentaurin.* This is almost insoluble in cold water, but dissolves in alcohol, melts at 136° C. and is reddened by exposure to sunlight. Various authors assign a different chemical formula to it (see Reis, *Ap. Ztg.*, 1911, p. 148). It is not bitter and therefore cannot be regarded as the active principle. Herissey and Bourdier (*J. P. C.*, 1908) claim to have found a glucoside which they named *erytaurin,* but Reis was unable to confirm their results. The active principle of the drug is unknown.

Uses.—Centaury possesses the bitter properties of the gentians and is useful as a stomachic. There is no reason, however, to suspect that it possesses any virtue beyond that of the more frequently prescribed *Gentiana*. It is more frequently employed as a domestic remedy than by physicians.

Dose, twenty to forty grains (1.3 to 2.6 Gm.).
Off. Prep.—Tinctura Amara, *N. F.*

CERA ALBA. U. S., Br.

WHITE WAX Cer. Alb.

"Yellow Wax, bleached." *U. S.* "White Beeswax is Yellow Beeswax, bleached." *Br.*

White Beeswax; Cire Blanche, *Fr. Cod.;* Cera alba, *P. G.;* Weisses Wachs, *G.;* Cera bianca, *It.;* Cera blanca, *Sp.*

CERA FLAVA. U. S., Br.

YELLOW WAX Cer. Flav. [Beeswax]

"Yellow Wax is obtained by melting and purifying the honey-comb of the bee, *Apis mellifera,* Linné (Fam. *Apidæ*)." *U. S.* "Yellow Beeswax is obtained from the honeycomb of the Hive Bee, Apis mellifica, *Linn.,* and possibly other species of Apis." *Br.*

Yellow Beeswax; Cera Citrina; Beeswax; Cire Jaune, *Fr. Cod.;* Cire d'Abeilles, *Fr.;* Cera Flava, *P. G.;* Gelbes Wachs, *G.;* Cera gialla, Cera vergine, *It.;* Cera amarilla, *Sp.*

The name *Apis mellifera* was given to the honey-bee of Linnæus in 1758, *Systema Naturæ,* 10th edition; subsequently (*Ibid.,* 12th edition, 1767), Linnæus changed the name to *mellifica,* but according to the established rules of scientific nomenclature the first name must hold, and the revisers of the United States Pharmacopœia were therefore correct in adopting it. It was at one time doubtful whether the wax which constitutes the walls of the honey-comb is elaborated or merely gathered by the insect. Huber, however, by feeding bees exclusively on honey and water, determined that under these circumstances wax is produced in the form of scales under the rings of the abdomen. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils. Besides the official species other bees are used as honey makers. The extremely vicious, blackish-brown *Apis fasciata* was kept by the ancient Egyptians on floating apiaries, which as the season progressed slowly drifted down the Nile, following the successive opening of the flowers. In Senegal, *Apis adansonii,* and in Southern Africa, *Apis caffra* and *Apis scutellata* produce honey; while the *Apis unicolor* of Madagascar has been domesticated in that island and introduced into other parts of the world. In India honey is made in large quantities by *Apis dorsata* (*Apis indica, Apis florea*) the largest bees known. *India Wax* differs from official wax chiefly in its lower acid value. A wax is also produced in India by the so-called *Kota bees,* belonging to the genus *Melipona;* they are minute stingless insects, which furnish a sticky, dark-colored wax, resembling in physical and chemical characteristics the propolis of the honey bee rather than the true wax.

Propolis or *bee-glue* is a brownish resinous substance sometimes deposited at the base of the hive; apparently it is collected from the resinous exudate of various trees such as the balsam, poplar and conifers. It has been used

1. Cera Flava, or *Yellow Wax.*—This is obtained by slicing the comb taken from the hive, removing the honey by centrifugal action, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate and either subside or be dissolved by the water. When the liquid cools the wax concretes, and, having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. The labor saving device is sometimes adopted of stretching a strainer of cheese cloth upon a hoop and wedging the latter down into the hot mixture below the level of the water; as this cools, the melted wax slowly rises through the cloth, and thus a perfectly clean cake of wax is formed on top on cooling. It is usually brought to market in round flat cakes from three to six inches in thickness.

Description and Physical Properties.—"A solid, varying in color from yellow to grayish-brown. It has an agreeable, honey-like odor, and a faint, characteristic taste. When cold, it is somewhat brittle, and when broken presents a dull, granular, non-crystalline fracture. It becomes plastic from the heat of the hand. Yellow Wax is insoluble in water and sparingly soluble in cold alcohol. Boiling alcohol dissolves the cerotic acid and a portion of the myricin, which are constituents of Yellow Wax. It is completely soluble in chloroform, ether, and in fixed or volatile oils, partly soluble in cold benzene or in carbon disulphide, and completely soluble in these liquids at about 30° C.

"Specific gravity: 0.950 to 0.960 at 25° C. determined as follows: Melt the Wax at a low temperature, and allow it to fall in separated drops from just above the surface into alcohol that has been warmed to from 45° to 50° C. Allow the globules to remain in the alcohol until it has cooled spontaneously to room temperature (20° to 25° C.), then remove the Wax and keep it at room temperature for twenty-four hours. Prepare a mixture of four volumes of alcohol and enough distilled water to make ten volumes, and allow it to stand until free from air bubbles. Moisten the globules of Wax with distilled water by means of a brush, and place them by means of forceps in the alcohol solution just prepared and contained in a beaker. Then add alcohol, or air-free distilled water, as required, to the mixture, kept at 25° C., until the globules of the Wax float and rest indifferently in the liquid. Finally determine the specific gravity of the alcohol-water mixture. The figure thus obtained represents the specific gravity of the Wax examined. Yellow Wax melts between 62° and 65° C.

"Boil 1 Gm. of Yellow Wax for half an hour with 35 cc. of an aqueous solution of sodium hydroxide (1 in 7), the volume being preserved by the occasional addition of distilled water: on cooling, the Wax separates without rendering the liquid opaque, and no precipitate is produced in the liquid after filtration through glass wool or asbestos on the addition of an excess of hydrochloric acid (*fats or fatty acids, Japan wax, rosin or soap*). Warm about 3 Gm. of Yellow Wax, accurately weighed, in a 200 cc. flask with 25 cc. of neutral dehydrated alcohol until melted, add 1 cc. of phenolphthalein T.S., and while warm titrate with half-normal alcoholic potassium hydroxide until a permanent, faint pink color is produced: the acid number so obtained is not less than 18 and not more than 24. Now add 25 cc. of half-normal alcoholic potassium hydroxide and 50 cc. of alcohol, boil the mixture for four hours under a reflux condenser, and titrate the excess of the alkali with half-normal hydrochloric acid: the ester number so obtained is not less than 72 and not more than 77." *U. S.*

"A yellowish-brown solid; somewhat brittle when cold, but becoming plastic by the heat of the hand. Agreeable, honey-like odor. Fracture granular, not crystalline. Soluble in *chloroform,* and in fixed and volatile oils. Specific gravity 0.958 to 0.970. Melting point 61° to 64° C. *Refractive index* at 80° C. 1.4380 to 1.4420. When 5 grammes are boiled for ten minutes with 80 millilitres of an aqueous solution (1 in 10) of *sodium hydroxide,* the water lost by evaporation being made up, the resulting solution, cooled and filtered through asbestos, does not become turbid when acidified with *hydrochloric acid* (absence of fats, fatty acids, Japan wax, resin). 5 grammes heated with 20 millilitres of *absolute alcohol,* and shaken until uniformly distributed, require for neutralisation at boiling temperature not less than 1.5 and not more than 2.0 millilitres of *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (limits of free acid). Upon the further addition of 20 millilitres of *N/1 alcoholic solution of potassium hydroxide,* and on well boiling for one and a quarter hours in a flask to which a reflux condenser is attached, not less than 13.2 and not more than 13.8 millilitres of *N/1 solution of sulphuric acid* are required for neutralisation. When 5 grammes are boiled with a mixture of 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* and 15 millilitres of *absolute alcohol* until completely saponified, the alcohol evaporated, the residue dissolved in 20 millilitres of *glycerin* on a water-bath and 80 millilitres of boiling *water* added, a clear or translucent solution is obtained (absence of ceresin, paraffin and other waxes). Not more than 1 per cent. is soluble in boiling *water* (limit of honey)." *Br.*

Dieterich examined hundreds of specimens annually, and found the wax to vary in sp. gr. from 0.963 to 0.966. He also determined the specific gravities of the following substances some of which are used to adulterate wax: white wax, 0.973; cera japonica, Japan wax, 0.975; ceresin, half white, 0.920; ozokerite, crude, 0.952; rosin, common, 1.108; cacao butter, 0.980 to 0.981; pure rosin, 1.045; beef suet, 0.952 to 0.953; yellow wax, 0.963 to 0.964; ceresin, white, 0.918; ceresin, yellow, 0.922; spermaceti, 0.960; French rosin, 1.104 to 1.105; paraffin, med. hard, 0.913 to 0.914; stearin, A No. 1, 0.971 to 0.972; mutton suet, 0.961.

2. CERA ALBA, *Bleached Yellow Wax,* or *White Wax.*—The color of yellow wax is discharged by exposing it, with an extended surface, to the combined influence of air, light and moisture. The process of bleaching is carried on to a considerable extent in this country. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribbon-like layers. These, having been removed, are spread upon linen cloths stretched on frames and exposed to the air and light, care being taken to water and occasionally turn them. In a few days they are partially bleached; but, to deprive the wax completely of color, it is necessary to repeat the whole process once, if not oftener. When sufficiently white, it is melted and cast into small circular cakes. Yellow wax may also be decolorized by treatment with animal charcoal or with potassium permanganate, potassium dichromate and sulphuric acid, and hydrogen peroxide. White wax sometimes contains one or more free fatty acids, consequent probably upon the employment of alkalies in bleaching it, which render it an unfit ingredient in the unctuous preparations of certain salts. It may be deprived of these acids by means of alcohol.

WHITE WAX is less unctuous to the touch than the yellow, soft and ductile at 35° C. and fusible at 65° C., retaining its fluidity at a lower temperature.

Description and Physical Properties.—"A yellowish-white solid, somewhat translucent in thin layers. It has a faint, characteristic odor, is free from rancidity, and is nearly tasteless. The acid value is not less than 17 and not more than 23, and the ester value not less than 72 and not more than 79, as determined by the methods under *Cera Flava.* In other respects White Wax has the characteristics of, and responds to, the tests for identity and purity under *Cera Flava.*" *U. S.*

"Hard, nearly white, translucent cakes or masses. 5 grammes heated with a mixture of 10 millilitres of *alcohol* (90 per cent.) and 10 millilitres of *absolute alcohol,* and shaken until evenly distributed, require for neutralisation at boiling temperature not less than 1.5 and not more than 2.2 millilitres of *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (limits of free acid). In other respects White Beeswax responds to the tests described under '*Cera Flava*'." *Br.*

By a great heat it is partly volatilized, partly decomposed; and, when flame is applied to its vapor, it takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly soluble in boiling alcohol and ether, which deposit it in a great measure upon cooling. The volatile and fixed oils dissolve it with facility, rosin readily unites with it by fusion, and soaps are formed by the action of sodium and potassium hydroxides. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid.

Composition.—The chief constituent of beeswax is *myricin* (*myricyl palmitate*); melting point 64° C. It also contains *cerotic acid* (formerly called *cerin*), $C_{26}H_{52}O_2$, and *melissic acid,* $C_{30}H_{60}O_2$. There are also present about 6 per cent. of hydrocarbons of the paraffin series, including *heptacosane,* $C_{27}H_{56}$, and *hentracontane,* $C_{31}H_{64}$. *Myricyl alcohol,* $C_{30}H_{61}OH$, is liberated when myricyl palmitate is saponified, as glycerol is liberated during the saponification of ordinary fats; when fused with potash lime it is converted into *potassium melissate,* $KC_{30}H_{59}O_2$. Hot alcohol extracts the cerotic and melissic acids from beeswax. Saponification, of course, decomposes the myricyl palmitate. Schwalb (*Ann. Chem.*, ccxxiv, 225) found melissic acid and some unsaturated acids of the oleic series; also higher solid hydrocarbons of the saturated series, such as $C_{27}H_{56}$ and $C_{31}H_{64}$. Kebler states that the hydrocarbons in beeswax amount to from 12.72 to 13.78 per cent. (*A. J. P.*, 1893, 587.) T. Marie believes that cerotic acid, as ordinarily obtained, is a mixture of two distinct acids. He gives $C_{30}H_{60}O_2$ as the formula for melissic acid and $C_{25}H_{50}O_2$ for pure cerotic acid.

Adulterations.—Wax has been variously adulterated. Heavy substances sink to the bottom of the vessel when the wax is melted. Starch, meal, and other insoluble substances remain behind when the wax is dissolved in oil of turpentine or petroleum benzin. Water, which is said to be sometimes fraudulently incorporated with it, by agitation when partially melted, is driven off by heat. Fatty substances render lime water turbid when agitated with it and allowed to stand. The best test for fats, fatty acids, or rosin is the pharmacopœial test of boiling with sodium hydroxide solution and testing the filtrate obtained after cooling. For the detection of rosin, cold alcohol is sufficient. It dissolves the rosin, and yields it on evaporation, attended with a very small portion of pure wax, which yields 2.4 per cent. to cold alcohol. F. Jean states that a few drops of sulphuric acid added to the melted wax adulterated with rosin, cause a red color, or, if only 1 per cent. be present, a green tint. (*A. J. P.*, 1881, p. 307.) To detect Japan wax, Dullo boils together for a minute 10 Gm. of wax, 120 Gm. of water, and 1 Gm. of sodium hydroxide; if Japan wax be present, a soap will immediately form, which will slowly solidify on cooling. Beeswax does not saponify under these circumstances. (*J. P. C.*, 4e sér., i, 448.) Ceresin, a principle obtained from ozokerite (see Part II), is also employed as an adulterant, and is manufactured largely for that purpose in Vienna. It is only native paraffin, and of course answers to the tests for that substance. There are other less precise methods of detecting adulterations. Thus, spermaceti and lard render wax softer and less cohesive, of a smoother and less granular fracture, and of a different odor when heated. The melting point and specific gravity are lowered by tallow, suet, lard, and especially by paraffin. *Legrip's cereometer* is based upon the altered specific gravity of wax when adulterated. Anyone may apply this principle by making such a mixture of alcohol and water that pure wax will neither sink nor rise in it, but remain wherever placed. Adulterated wax would either float or sink in this liquid. The most valuable information, however, is obtained by the determination of the chemical constants—viz., acid value, ester value, and saponification value. In yellow wax the iodine value is also of use; in white wax the bleaching process has altered the bodies which absorb the iodine. (See also *Chem. Ztg.*, 1893, 918; *Proc. A. Ph. A.*, 1894, 957; *D. C.*, 1898, 33; *Am. Drug.*, 1898, 97, and 1904, 103, 105.) According to G. Brehner (*Ztsch. Off. Ch.*, 1912, No. 5), who has investigated many samples of beeswax of normal and abnormal character, beeswax may be divided into three groups, according to source, as follows: (1) Ordinary normal beeswax in which the ratio of acid number to ester number is 1 : 3.6 to 1 : 4. (2) Beeswax of African origin in which the ratio is 1 : 3. (3) Beeswax of Indian origin in which the ratio is 1 : 12. A Leijs (*J. P. C.*, 1912, No. 12) describes a method—based on the relative solubility in fuming hydrochloric acid—which, he claims, enables him with certainty to separate paraffin, ceresin, and carnauba wax readily from beeswax.

Under the name of White Wax No. 2 or White Wax for technical use, there has been found in commerce a product put up in exact imitation of white beeswax, and consisting of over 90 per cent. of paraffin.

VEGETABLE WAX.—Many vegetable products contain wax. It exists in the pollen of numerous plants, and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it is so abundant as to be profitably extracted for use. Such is the *Ceroxylon andicolum* Humb., a lofty palm growing in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance and one-third of pure wax. Two kinds of wax are collected in Brazil, one called *carnauba,* from the leaves of the *Copernicia cerifera,* a palm, which forms large forests in the provinces of Ceara, the other *ocuba,* from the fruit of a shrub of the province of Para. (*J. P. C.,* 3e sér., v, 154.)

Carnauba wax is collected by cutting out the leaf buds of *Copernica cerifera* (Arruda) Mart. (Fam. *Palmaceæ*), commonly called the *Brazilian Wax Palm,* drying and beating them, and melting the powder thus detached, in water. The principal constituent of Carnauba wax is *myricyl alcohol,* $C_{30}H_{61}OH$, which is present to the extent of nearly 50 per cent. *Myricyl cerotate* is also present, as is *cerotic acid,* $C_{26}H_{52}O_2$, and *ceryl alcohol,* $C_{27}H_{55}OH$. There are some unidentified paraffin-like carbohydrates present and a dihydric alcohol of the composition $C_{23}H_{46}(CH_2OH)_2$, and the corresponding acid $C_{23}H_{46}(COOH)_2$. An acid isomeric with *lignoceric acid,* $C_{23}H_{47}COOH$, melting point 72.5° C., is also present. Over 50 per cent. of Carnauba wax is unsaponifiable. The constants, according to Radcliffe (*J. Soc. Chem. Ind.,* 1906, xxv, p. 158) are as follows: Sp. gr. 0.999, melting point 84° C., acid value 2.9, saponification value 88.3, ester value 85.4, iodine value 13.2. It is hard, brittle, and buff-colored, yellow, or greenish, resembling the resins more than wax, and melts at 84° C. which is much higher than the fusing point of other kinds of vegetable wax. It takes a fine polish when rubbed with any soft material, does not receive impressions from the finger at the natural temperature of the hand, and is adapted for polishing furniture, either alone or mixed with other varieties of wax. 2,000,000 pounds of it are said to be annually produced in Brazil, where it is largely used, mixed with tallow, in making candles, etc. (See also *P. J.,* 1904, 26.) (See also *Carnauba Root,* Part II.)

China wax, or *Chinese insect wax,* called *pe-la* by the Chinese, resembles spermaceti in whiteness and crystalline appearance, but is distinguished by greater hardness and friability and a somewhat fibrous fracture. It melts at about 83° C., is very slightly soluble in alcohol or ether, is insoluble in cold oil of turpentine and rectified petroleum, but is dissolved with the aid of heat, and is very soluble in benzene. These solubilities distinguish it from spermaceti. (*P. J.,* xiv, 9.) It was formerly supposed to be of vegetable origin, but has been ascertained to be the product of an insect, *Coccus ceriferus,* deposited on the twigs of the Chinese Ash, *Fraxinus Chinensis* Roxburgh, and investing them closely; the insect becomes embedded in a waxy material, which is scraped off with the insects, and constitutes the crude wax. It is purified by melting and straining. It is one of the chief industries in the province of S'zchuan, second only in importance to the silk culture. It is used over the entire Empire for candles and as medicine. (For details of its collection see *U. S. D.,* 19th ed., p. 307; also *P. J.,* 1885, xv.)

Under the name of *Ocotilla wax,* Helen Abbott Michael described (*A. J. P.,* Feb., 1885) a vegetable wax obtained from the bark of *Fouquiera splendens* (Tor.) Engelm. (Fam. *Tamaricaceæ*) known familiarly in Texas as *coachwhip cactus.*

Pisang Wax from *Ficus cerifera,* according to Greshoff and Sack, occurs in white crystalline cakes, having the sp. gr. 0.963 to 0.970 at 15° C., and melting at 79° to 81° C. It is very sparingly soluble in ethyl alcohol, even when boiling, but readily soluble in boiling oil of turpentine, amyl alcohol, and carbon disulphide. Its acid number is 2 to 3, its saponification number 109. *Pisang-cerylic acid,* obtained by saponification, melts at 71° C., and has the composition $C_{24}H_{48}O_2$; while *pisang-cerylic alcohol,* which was also isolated, melts at 78° C., and has the formula $C_{13}H_{18}O$.

Gondang Wax occurs in brown pieces which are yellowish internally and have a sp. gr. of 1.015. In distinction from pisang wax, gondang wax is soluble in all the usual solvents at a boiling temperature, and it may be almost completely dissolved by prolonged boiling with ethyl alcohol, being, however, again deposited on cooling. Gondang wax purified in this way melted at 61° C., and yielded *fico-cerylic acid* on saponification, which has the formula $C_{13}H_{26}O_2$, and melts at 57° C., while *fico-cerylic alcohol* has the formula $C_{17}H_{28}O$, and melts at about 198° C. In its general character gondang wax is intermediate between wax and caoutchouc. (*Ph. Ztg.,* 1901, 563.)

Japan Wax has been imported into Europe in considerable quantities, either directly from Japan, or through the Chinese ports. It is obtained from the berries of the *Rhus succedanea* of Linnæus, and in small amount from the *R. sylvestris* and *R. vernicifera,* or lacquer plant. The partially dried berries are crushed, winnowed, steamed, placed in hemp cloth bags, steamed again, and pressed in a wooden wedge press. They yield about 15 per cent. of a coarse greenish tallowy mass. It bears a considerable resemblance to purified beeswax, but is not quite so white, having a slightly yellowish tint, is softer, more friable, and has a somewhat rancid odor and taste. Its melting point is below that of wax, varying from 42° C. to 55° C. It is much more soluble in alcohol than is beeswax, and is saponifiable with the alkalies. It is not a true wax, being, in the main, a glyceride of palmitic acid with smaller amounts of the glycerides of stearic and arachidic acids. It has been employed in the preparation of candles, which yield as brilliant light as those made of common wax. It has been found useful in the preparation of cerates, etc.

Myrtle Wax is obtained from several species of *Myrica,* notably the *M. cerifera* L. and the *M. Xalapensis* H. B. K. of Cape Colony. The former known popularly as *wax myrtle,* or *bayberry,* is an aromatic shrub from one to fifteen feet high, growing in the United States, from New Jersey to Louisiana, and flourishing especially along the sea coast. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coat of wax, which may be separated for use. Other parts of the plant are said to possess medicinal virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed in jaundice. The process for collecting the wax is simple. The berries are boiled in water, and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to concrete as the liquor cools, and then removed. To render it pure, it is again melted and strained, and cast into large cakes. It is of a pale grayish-green color, somewhat diaphanous, more brittle and unctuous to the touch than beeswax, of a feeble odor, and a slightly bitterish taste. It is about as heavy as water, and melts, according to G. E. Moore, at from 46.6° to 48.8° C. It is insoluble in water, scarcely soluble in cold alcohol, soluble, excepting about 13 per cent., in twenty parts of boiling alcohol, which deposits the greater portion on cooling, soluble also in boiling ether, and slightly so in oil of turpentine. It is readily saponifiable with the alkalies. Myrtle wax consists chiefly of the glycerides of myristic, palmitic and stearic acids with small quantities of olein; it is, therefore, not a true wax but a hard fat. It has been popularly employed in the United States as a remedy for dysentery. It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparaction of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp oil. It is especially employed for making candles for use at the Christmas season.

A wax which is said to be used, under the name of *Árbol de la Cera,* in Mexico not only for domestic purposes, but also as a remedy in diarrhea and jaundice, is obtained by boiling the fruit of the *Myrica jalapensis* in water. It is greenish or yellow, more brittle and unctuous than beeswax, has a feeble odor, a slightly bitter taste, and a density nearly equal to that of water, and melts at 43° C.; but on exposure the fusing point rises to 47.5° C. It is wholly soluble in boiling ether, insoluble in water, sparingly soluble in cold alcohol, and dissolves in twenty parts of boiling alcohol, depositing the greater part on cooling; alkalies saponify it readily. (*A. J. P.,* xv, 339, 1885.)

Uses.—Wax has little effect upon the system. Under the impression that it sheathed the inflamed mucous membrane of the bowels, it was formerly prescribed in *diarrhea* and *dysentery;* and it is mentioned by Dioscorides as a remedy in the latter complaint; but at the present time, we suppose, no one would think of employing wax for such purposes. Its sole use in modern medicine is in the formation of ointments, cerates, plasters, suppositories, and surgical dressings, etc.; in which it acts mechanically either giving stiffness or serving to protect from water. It is an ingredient in almost all the official cerates, which owe to it their general title.

Yellow wax.—Ceratum Cantharidis, *U. S.* (*Br.*)*;* Ceratum Resinæ, *U. S.* (*Br.*)*;* Ceratum Resinæ Compositum, *N. F.;* Linimentum Terebinthinæ (from Rosin Cerate), *Br.;* Unguentum, *U. S.*

CERATA.

CERATES

Cérats, Céréolés, Elæocéréolés, *Fr.;* Cerate; Wachssalben, *G.*

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or rosin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and that of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should always be taken to select the oil or lard perfectly free from rancidity. In reference to the wax, too, there would seem to be a choice, as experience has shown that cerates made with yellow wax keep longer unchanged than those made with white or bleached wax, probably because there is in yellow wax some principle which corrects the tendency of fatty matters to become rancid. The liquefaction should be effected by a very gentle heat, which may be applied by means of a water bath, and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence. When a large qantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates, but the great tendency to produce granulation in the finished cerate has largely prevented its use.

It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia, the several cerates having been rejected, or transferred to the class of ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is ground for difference between them and the ointments in their consistence, that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments is peculiarly adapted to inunction. W. H. Mielcke (*Ph. Cb.,* 1881, Nos. 20, 21) proposes a class of preparations, to which he has given the name "*Steatins.*" These are of about the consistence of cerates, of varied composition, and contain usually a considerable portion of tallow. The *Steatinum Iodoformi* offers a fair specimen of the class. "Take of mutton tallow 18 parts, expressed oil of nutmeg 2 parts, iodoform, in fine powder, 1 part. Melt the tallow and add the other ingredients." For other formulas, see *A. J. P.*, 1881, p. 404.

CERATUM. U. S.

CERATE Cerat. [Simple Cerate]

Ceratum Adipis, *U. S.* 1860; Ceratum Simplex, *U. S.* 1850; Cérat Simple, *Fr. Cod.*; Unguentum cereum, *P. G.*; Einfaches Cerat, Wachssalbe, *G.*; Cerato simple, *Sp.*

"White Wax, 300 Gm.; Benzoinated Lard, 700 Gm.; to make 1000 Gm. Melt the white wax by the heat of a water bath, add the benzoinated lard, continue the heat until the mixture is liquefied, strain if necessary, and stir constantly until it congeals. For use in southern latitudes and during the heated season in other localities, 50 Gm. of benzoinated lard (or more, if necessary) may be replaced by an equal quantity of white wax." *U. S.*

In the U. S. Pharmacopœia VIII 20 per cent. of white petrolatum, and 50 per cent. of benzoinated lard were directed in place of the 70 per cent. of lard used in the U. S. P. (1890) process. In the present official cerate the white petrolatum was omitted. In the preparation of cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition, for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing *blisters, wounds,* etc., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose benzoinated lard should be used in winter, and simple ointment in summer, the cerate having too firm a consistence. George W. Sloan recommended the use of simple cerate as a pill excipient for certain oxidizable substances and special uses. (*Proc. A. Ph. A.*, 1884.)

CERATUM CANTHARIDIS. U. S.

CANTHARIDES CERATE Cerat. Canthar. [Blistering Cerate]

Emplastrum Cantharidini, *Br.*; Cantharides Plaster; Emplastrum Epispasticum, s. Vesicatorium, s. Vesicans, Emplastrum Lyttæ; Blistering Cerate or Plaster; Emplâtre Vesicatoire, *Fr. Cod.*; Pommade Epispastique, Emplâtre de Cantharides, *Fr.*; Emplastrum Cantharidum Ordinarium, *P. G.*; Spanischfliegen Pflaster, Blasenpflaster, *G.*; Pomata di cantaridi, *It.*; Unguento de cantharidas. *Sp.*

"Cantharides, in a very fine powder, 350 Gm.; Glacial Acetic Acid, 25 cc.; Oil of Turpentine, 150 cc.; Yellow Wax, 175 Gm.; Rosin, 175 Gm.; Benzoinated Lard, 200 Gm.; to make 1000 Gm. Moisten the cantharides with the oil of turpentine and the glacial acetic acid, previously mixed, and set the mixture aside in a well-covered container in a warm place for forty-eight hours. Melt together the rosin, yellow wax, and benzoinated lard, strain the mixture through muslin, add the macerated cantharides, and keep the mixture in a liquid condition by heating it on a water bath with occasional stirring until it is reduced in weight to 1000 Gm. Then withdraw the heat, and stir the Cerate until it becomes firm." *U. S.*

This is the commonly called *blistering plaster.* As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. The U. S. P. IX has recognized a plaster in which this cerate is spread upon fabric, while the British Pharmacopœia contains a preparation similar to the U. S. cerate, under the title *Emplastrum Cantharidini.* In the Br., however cantharidin is used instead of cantharides. (See also *Emplastrum cantharidis.*)

"Cantharidin, 2 *grammes;* Chloroform, 100 *millilitres;* Yellow Beeswax, 450 *grammes;* Wool Fat, sufficient to produce 1000 *grammes.* Dissolve the Cantharidin in the Chloroform by the aid of heat, add to the other ingredients previously melted on a water-bath, and stir until cold. This Plaster contains 0.2 per cent. of Cantharidin, which is approximately the proportion contained in the Emplastrum Cantharidis of the British Pharmacopœia, 1898." *Br.*

There can be no question of the advantage of retaining the cantharides in contact with hot liquefied fatty bodies to facilitate the extraction of the cantharidin.

It was at one time recommended that the mixture of cantharides and oil be heated to a temperature of 121° C., the advantage being claimed that the contained moisture of the cerate is boiled off at this temperature and also that the solution of active principle is encouraged, but as it has been shown that cantharidin begins to volatilize at a temperature of 100°, it is evident that the use of this method must be attended with a considerable loss of drug. Dieterich states that the activity is greatly increased by the use of an acid in the manufacture. Thus, for every 250 Gm. of powdered flies used he adds to the melted mass 1 Gm. sulphuric acid and 10 Gm. alcohol (90 per cent.), keeps the mass for two hours at 70° C., and finally adds 2 Gm. barium carbonate rubbed up with 6 Gm. alcohol. (*Ph. Centralh.*, 1892, 425.) It is desirable that the flies should be very finely pulverized. Coarsely powdered cantharides should not be used, because of the imperfect and unequal distribution of the vesicating agent. Powdered euphorbium is said to be sometimes fraudulently added.

Uses.—This cerate is used solely as a vesicant and is one of the most efficient preparations of cantharides for this purpose in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread on soft leather or linen and applied to skin as a plaster. Heat is not requisite, and should not be employed in spreading the cerate. Some operators sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. The practice of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, renders the preparation more certain.

For details of the methods of using, see under *Emplastrum Cantharidis.*

Off. Prep.—Emplastrum Cantharidis, *U. S.*

CERATUM RESINÆ. U. S. (Br.)

ROSIN CERATE Cerat. Res.

Unguentum Resinæ, *Br.;* Resin Ointment; Ointment of Resin, Unguentum Basilicum; Basilicon Ointment; Unguentum Tetrapharmacum; Resin Ointment, Resin Cerate; Pommade Basilicum, *Fr. Cod.;* Onguent Basilicum, Cérat de Résine Anglais, *Fr.;* Harzcerat, Harzsalbe, Königsalbe, Zugsalbe, *G.*

"Rosin, 350 Gm.; Yellow Wax, 150 Gm.; Lard, 500 Gm.; to make 1000 Gm. Melt the rosin, add the yellow wax and lard, and continue the heat until liquefied, then strain the liquid through muslin, and allow it to congeal, stirring occasionally.

"NOTE.—In cold weather 530 Gm. of lard and 120 Gm. of yellow wax may be used." *U. S.*

"Resin, 26 *grammes;* Yellow Beeswax, 26 *grammes;* Olive Oil, 26 *grammes;* Prepared Lard, 22 *grammes.* Melt together; strain; stir until cold. In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The U. S. preparation does not differ greatly from that formerly official except that occasional stirring while congealing is directed; the U. S. P. 1890 process forbade stirring. The British process (1898) discards the simple ointment and almond oil previously used (1885), and substitutes lard and olive oil. *Ceratum Resinæ Composition*—Compound rosin cerate. *Deshler's Salve* was dropped from the U. S. P. IX. It is retained in the N. F. (see Part III). It is made from rosin, yellow wax, prepared suet, turpentine (white) and linseed oil, and is used for the same purposes as Ceratum Resinæ. Rosin cerate, commonly called *basilicon ointment,* is much used as a gently stimulating and protective application to *blistered surfaces, indolent ulcers, burns, scalds,* and *chilblains.* We have found no application more effectual in disposing the *ulcers* which follow *burns* to heal.

Off. Prep.—Linimentum Terebinthinæ, *N. F.*

CEREVISIA FERMENTUM COMPRESSUM. N. F.

COMPRESSED YEAST Cerev. Ferm. Compr.

"Compressed yeast consists of the moist, living cells of *Saccharomyces cerevisiæ* Meyen or of other species of *Saccharomyces* (Fam. *Saccharomytaceæ*), combined with a starchy absorbent base. Compressed yeast must must nor be used unless fresh and free from mildew and musty or foul odors." *N. F.*

Faex Medicinalis; Yeast, Leaven; Hefe, G.; Levure, *Fr.* Fermento, Lievito, *It.*

Baker's Yeast.—As was originally shown by Pasteur, the decomposition of glucose into alcohol and carbonic acid is accomplished by means of a living ferment known as yeast or leaven. The name *Torula cerevisiæ* was first given to the yeast plant, which was subsequently called *Mycoderma vini;* Reess, in his elaborate work (*Alkoholsgährungspilze,* Leipsic, 1870), made a distinct genus of it, *Saccharomyces,* including many species.

The wine-producing yeasts are varieties of the species *Saccharomyces ellipsoideus.* Brewers' yeast and that used for culinary purposes are varieties of *S. cerevisiæ.*

According to Casagrandi, *Saccharomyces ruber,* previously discovered by Demme, produces a *red yeast* which ferments glucose very readily, developing a red pigment. This saccharomyces was found pathogenic to various animals, and when put into milk so modified that liquid as to convert it into a pronounced intestinal irritant. (*P. J.,* Jan., 1898.) A number of yeasts are used in China and Java whose fundamental plants are different from those of the European yeast. See *P. J.,* vol. xlvii.

Two well-marked varieties of the *Saccharomyces cerevisiæ* have been recognized. The one is the most active at the ordinary temperature (16°–20° C.), and carries through its fermentative work in from three to four days; the other works at a lower temperature (6°–8° C.), and the fermentation is much slower. The first placed in a saccharine liquid is carried by the carbon dioxide which it liberates to the surface of the liquid, where it continues its activity; it is, therefore, known as a *surface* or *top yeast.* The second, on the contrary, is not carried up, and rests during its entire activity on the bottom of the fermenting vessel, and is hence called a *bottom yeast.* Two quite distinct methods of beer brewing are practised, depending upon the use of the one or the other of these varieties of yeast. (For fuller information as to the nature of *yeast* and its conditions of culture and activity, see Sadtler's *Industrial Organic Chemistry,* Philadelphia, 4th ed., 1921.)

Brewers' yeast is a flocculent, frothy, somewhat viscid semi-fluid, of a dirty yellowish color, a sour, vinous odor, and a bitter taste. Exposed to a moderate heat the moisture evaporates and it becomes dry, hard, and brittle, and may in this state be preserved for a long time, though with the loss of much of its enzymic power. *Yeast cakes* are made by putting yeast into sacks, washing it with water, then submitting it to pressure, and ultimately drying it.

Description and Physical Properties.—"White or yellowish white, soft and easily broken masses, having a characteristic, slightly sour odor, and not more than a faintly acid reaction to litmus. When examined with the microscope, numerous oidium and mycoderma cells and starch grains are visible." *N. F.*

Compressed yeast usually comes in square blocks weighing about one-half ounce each.

Compressed yeast, according to an analysis by Hawk, Smith and Holder (*A. J. Phys.*, 1919, xlviii) contains on a water free basis 52.4 per cent. of protein, 37.1 per cent. of carbohydrate, 1.7 per cent. of fat and 8.7 per cent. of ash, the latter being chiefly potassium phosphate. Funk, Lyle and McCaskey (*J. Bi. Chem.*, 1916, xxvii, p. 173), from experiments in which yeast was the sole source of protein, reached the conclusion that the yeast nitrogen was so poorly uitilized by the human economy that yeast possessed no food value. Hawk, Smith and Holder, however, found that from 10 to 30 per cent. of the nitrogenous elements of the food can be replaced by yeast nitrogen without detriment to the nutrition. While we believe that it must be conceded that yeast has a definite food value, the quantities that can be employed as a foodstuff are rather limited by two factors: one, the difficulty of preparing large amounts in a palatable form, and the other, the fact that considerable quantities of yeast have a definite laxative action.

Yeast contains a considerable quantity of nucleic acid.

According to Albert Buchner and Rapp, a dried yeast which retains its activity on keeping is obtained as follows: The yeast is freed from water as much as possible by expression, immersed in acetone and rubbed through a sieve. The acetone is decanted, renewed, again decanted, and the residue collected by the aid of a suction filter, then treated with ether for three minutes, and this removed in the same way, after which the yeast is spread out to dry, the drying being completed at a temperature of 45° C. Dried yeast, so obtained, is an almost white powder. (*Ph. Centralh.*, 1903, 36.)

Yeast consists of numerous cells, irregular, roundish, or cylindrical in shape, separate, joined into rows, or budding one from the other. It is most probable that the yeast plant is the mycelium, or early vegetative stage, of more than one species of mucor or mould.

Starch as such is not subject to fermentation by the yeast plant but the latter contains an enzyme which is capable of inverting starch into sugar, the latter of which is utilized by the growing micro-organisms, with the characteristic sugar decomposition. Formerly, it was thought that glucose was the only food necessary for the growth of yeast but more recent evidence indicates that yeast is unable to multiply in the complete absence of protein. In other words, both sugar and nitrogenous principles are requisite for culture media for yeast.

Uses.—Yeast has been employed as a medicine both by the regular profession and as a folk remedy for many years. Its most popular and best supported use has been in skin infections such as *furunculosis* and *acne*. Hawk and his co-workers have found it also of use in *chronic constipation* and Spencer (*T. G.*, May, 1920) in *arthritis deformans*.

Various theories of the mode of action of yeast have been suggested but none of them demonstrated. Some writers have believed that its action is due to the high nuclein content, the latter acting as a stimulant to the formation of leukocytes (see *Nuclein*, Part II). Some investigators have attributed it with a direct bactericidal power. Tsuru (*W. K. R.*, 1909) has shown, however, that this is true only to growing yeast and it could hardly, therefore, explain the benefit which has followed its internal administration. As was first shown by Hopkins (*J. P.*, 1912, xliv, p. 425) and subsequently confirmed by various numbers of investigators, yeast is comparatively rich in the water-soluble vitamine. (See Hawk, Smith and Bergeim, *A. J. Phys.*, 1921, lvi, p. 33.) Osborne and Mendel (*J. Bi. Chem.*, 1919, xxxviii, p. 223) maintained rats in health for over a year on a diet in which yeast was the sole source of both protein and water-soluble vitamine B. Saleeby (*Philippine Journ. Science*, 1919, xiv, p. 11) has found it will cure *beri-beri*. Some have attributed its beneficial effects to the vitamine content but we have no convincing evidence of any beneficial effects of excessive vitamine. It is possible that its ferment action may inhibit the growth of certain putrefactive organisms in the intestinal canal and hence improve the general health or it is at least conceivable that the mild laxative action is the real basis of its curative effects.

In the light of our present knowledge, all that we can say about the medicinal use of yeast is that there is considerable clinical evidence as to its value in staphylococcic infections but that there is no established explanation of its *modus operandi*.

A large number of preparations of yeast have been placed upon the market under the various trade names. Among these the following may be mentioned:

Xerase.—This is stated to be a mixture of yeast and kaolin with glucose and salts. This is a yellowish-gray powder, asserted to possess not only absorbent but also bactericidal powers. It is intended for local application, especially in *gonorrhea* of women.

Cerolin.—A fatty substance derived from yeast, asserted to represent the specifically active constituent of yeast. It is a yellowish to a brownish semi-fluid with an odor resembling that of yeast. It is used in dose of one and a half to three grains (0.1 to 0.2 Gm.). *Bajuvarin* is a preparation of yeast which is used both internally and locally by veterinarians. *Fermentine* is a preparation of yeast containing benzoin, used principally for local application. *Fermocyl:* A mixture of dried yeast, pancreas and sodium phosphate, marketed in the form of tablets, each corresponding to about 30 grains (2 Gm.) of the fresh yeast. Used in diabetes. *Furunculin: Dose,* ten to thirty grains (0.65–2 Gm.). *Levuretin, Levurin,* and *Leuvurinose* are proprietary forms of dried beer yeast; any of them may be given in doses of one drachm (3.9 Gm.). *Mycodermin:* Marketed only in pills. *Dose,* 2 to 4 pills. *Trygase: Dose,* one teaspoonful. *Zymin* is a dried yeast which is marketed either as a powder, intended for external use, or in the form of tablets each of which contains fifteen grains (1 Gm.).

Dose, of compressed yeast, is one to three drachms (4–12 Gm.).

CETACEUM. U. S., Br.

SPERMACETI Cetac.

"A fatty substance, obtained from the head of the sperm whale, *Physeter macrocephalus* Linné (Fam. *Physeteridæ*)." *U. S.* "Spermaceti is a solid wax obtained from the Sperm Whale, Physeter macrocephalus, *Linn.*, and possibly other species." *Br.*

Blanc de Baleine, *Fr. Cod.;* Spermacéti, Cétine Ambre Blanc, *Fr.;* Cetaceum, *P. G.;* Walrat, *G.;* Cetina, *It.;* Esperma de ballena, Sperma ceti, *Sp.*

The spermaceti whale is from sixty to eighty feet long, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated by cartilaginous partitions, and containing an oily liquid, which, after the death of the animal, concretes into a white spongy mass consisting of spermaceti mixed with oil. This mass is removed, and the oil allowed to separate by draining. The crude spermaceti obtained from a whale of the ordinary size is more than sufficient to fill twelve large barrels. It still contains much oil and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and repeated washing with a weak boiling potash lye. Common whale oil and the oil of other cetaceous animals contain small quantities of spermaceti, which they slowly deposit on standing. According to W. Gilmour, *sperm oil* should contain not less than 4 per cent. of cetin, and if much less be obtained by the following process, adulteration has been practised. Shake one part by weight of sulphuric acid (sp. gr. 1.84) with four parts of the oil; allow to stand 20 minutes, shaking twice; add three parts of distilled water; shake this thoroughly, and allow to stand from 16 to 20 hours; dilute with 3 or 4 times its volume of distilled water; agitate thoroughly. On standing, the cetin floats upon the top, and can readily be skimmed off, washed, dried, and weighed. (See also *Chem. Ztg.*, 1893, 1453, and *Am. Drug.*, 1895, 105.)

Description and Physical Properties.—"White, somewhat translucent, slightly unctuous masses, having a crystalline fracture, and a pearly luster. It has a very faint odor and a bland, mild taste. It is free from rancidity. Spermaceti is insoluble in water, nearly insoluble in cold alcohol, and only slightly soluble in cold petroleum benzin. It is soluble in boiling alcohol, ether, chloroform, carbon disulphide, and in fixed or volatile oils.

"Specific gravity: 0.938 to 0.944 at 25° C., as determined by the method given under *Cera Flava*, using alcohol warmed to from 38° to 40° C. Spermaceti melts between 42° and 50° C. It dissolves completely in fifty parts of boiling alcohol (*paraffin*), and the solution is neutral or not more than slightly acid to moistened litmus paper. Warm a mixture of about 1 Gm. of Spermaceti and 10 cc. of ammonia T.S. in a stoppered vessel until the Spermaceti is melted, shake it thoroughly for a few minutes, cool, and filter: on acidulating this filtrate with hydrochloric acid, it may become turbid, but yields no precipitate (*stearic acid*)." *U. S.*

"Translucent, pearly-white, glistening masses, with a leafy, crystalline structure; slightly unctuous to the touch. Almost inodorous. Specific gravity 0.950 to 0.960; *acid value* not more than 1.0; *saponification value* 125 to 136; *iodine value* 3 to 4.4; *refractive index* at 80° C. about 1.4330. Soluble in 50 parts of hot *alcohol* (90 per cent.), the greater proportion separating again in thin laminæ on cooling. Reducible to powder with the aid of a little *alcohol* (90 per cent.). When 1 gramme is boiled with 10 millilitres of *alcohol* (90 per cent.) for one minute and the mixture cooled to, and filtered at 0° C. the filtrate when poured into *water* may become opalescent, but does not afford a precipitate (absence of stearic acid)." *Br.*

As found in commerce it is not chemically pure, containing a fixed oil, and often a peculiar coloring principle. From these it is separated by boiling in alcohol, which on cooling deposits it in crystalline scales. Thus purified, it does not melt under 49° C., is soluble in 40 parts of boiling alcohol of the sp. gr. 0.821 (Thénard), and is harder, more shining, and less unctuous than ordinary spermaceti.

Spermaceti is a mixture of various fats. The chief constituent is *cetin* (*cetyl palmitate,* $C_{16}H_{33}O.C_{16}H_{31}O$). *Cetyl alcohol,* $C_{16}H_{33}OH$, is also present in appreciable amounts. There are small amounts of lauric, myristic, palmitic, and stearic acids, and also of dodecyl, tetradecyl and octadodecyl alcohols.

L. F. Kebler, after examining about twenty samples of spermaceti, found that commercial specimens have a melting point of from 42° to 47° C., a specific gravity ranging from 0.905 to 0.945 at 15° C., and saponification numbers from 125.8 to 134.6. (*A. J. P.*, 1896, 7, and 1897, 104.)

Uses.—Spermaceti exercises emollient effects like other fatty substances, but it has no other remedial properties. It is used chiefly to add firmness to ointment bases. It may be reduced to powder by the addition of a little alcohol or almond oil, or by melting it at a very low heat, pouring into a warm mortar, and agitating it until perfectly cold; an emulsion may be made by mixing spermaceti first with half its weight of olive oil, then with powdered gum arabic, and lastly with water. Spermaceti Cerate (*Ceratum Cetacei,* U. S. 1890) was made by melting together 10 parts of spermaceti and 35 parts of white wax and then adding 55 parts of warmed olive oil.

CHIMAPHILA. N. F.

CHIMAPHILA Chimaph. [Pipsissewa]

"Chimaphila consists of the dried leaves of *Chimaphila umbellata* (Linné) Barton (Fam. *Ericaceæ*). Chimaphila contains not more than 5 per cent. of its stems and other foreign organic matter." *N. F.*

Pipsissewa, Prince's Pine, Wintergreen, Bitter Wintergreen, King's Cure, Ground Holly, Love-in-winter, Rheumatism Weed; Herbe de Pyrole ombellée, *Fr.;* Doldenbluthiges Harnkraut, Wintergrün *G.*

The name chimaphila is formed of two Greek words, χεῖμα, winter, and φίλος, to love. There are two American species of the genus *Chimaphila,* only the *C. umbellata,* however, being official. This is a low perennial herb, 4 to 10 inches in height, bearing from 4 to 7 flesh-colored pedunculated flowers. The wedge-lanceolate leaves are sharply serrate and borne in irregular whorls, of which there are usually two on the same stem, thick and shiny, not spotted, remaining green through the winter. This plant is common in dry woods from Nova Scotia to Georgia and westward. It is also found in the northern latitudes of Europe and Asia. The drug is collected for the market chiefly in the southern Applachians and Michigan.

The *C. maculata* (L.) Pursh (*Spotted Wintergreen*) differs in having the leaves obtuse at the base and broader than at the summit, remotely toothed and the upper surface of a deep olive green variegated with white.

Description and Physical Properties.—"*Unground Chimaphila.*—Oblanceolate, from 2.5 to 7 cm. long and from 8 to 20 mm. wide, the upper portion coarsely and sharply serrate, acute or somewhat obtuse, the lower wedge-shaped and nearly entire; coriaceous, smooth and uniformly dark green on the upper surface, paler beneath, the veins prominent. Odor slight; taste astringent and bitter.

"*Powdered Chimaphila.*—Greenish brown; exhibits characteristic epidermal tissue composed of cells with unevenly thickened more or less porous and wavy vertical walls, with outer walls from 0.008 to 0.015 mm. thick; fragments from the lower epidermis with numerous broadly elliptical stomata, the latter up to 0.040 mm. long; fragments of palisade and spongy parenchyma containing chloroplastids; tracheæ with spiral or annular markings; a few characteristic, elongated tracheæ-like cells, about 0.014 mm. wide, thick-walled, slightly lignified and with minute double-spiral bands of delicate reticulations; parenchyma cells containing a reddish brown amorphous substance; calcium oxalate in rosettes mostly about 0.035 mm. in diameter, occasionally up to 0.065 mm. in diameter; starch grains few, rounded, simple, up to 0.016 mm. in diameter and sometimes with a central cleft or fissure, or 2- to 4-compound; hairs absent; a few fragments of epidermis from stems and root-stocks, the cells containing a purplish coloring substance which is intensified when the powder is mounted in chloral hydrate T.S." *N. F.*

Pipsissewa, when fresh and bruised, exhales a peculiar odor. Boiling water extracts the active properties of the plant, which are also imparted to alcohol. Fairbank found in the leaves a peculiar substance which he calls *chimaphilin.*

Chimaphilin was obtained by extracting the tincture with chloroform, or by distilling the stems with water. It occurs in golden-yellow acicular crystals, odorless and tasteless, practically insoluble in water, but dissolving in alcohol, ether, chloroform, and the fixed oils. It is possessed of neither acid nor alkaline properties. Peacock (*A. J. P.,* 1892, p. 295) found that chimaphilin has the chemical composition $C_{24}H_{21}O_4$.

Ridenour (*A. J. P.,* 1895, 236) confirms this formula. He finds the melting point of the purified chimaphilin to be 114° C. He also prepared another crystalline principle melting above 250° C., to which he gives the formula $C_{10}H_{19}O$. *Arbutin* is also found in chimaphila.

Uses.—This plant is stated to have been used internally by the North American Indians in *scrofula* and *rheumatism,* and was a popular remedy among the settlers of this country. It has no medicinal properties, however, beyond a feeble diuretic action and perhaps some antiseptic influence on the urine. It is occasionally prescribed for *cystitis.* The best preparation is the fluidextract, which may readily be made into a syrup.

Dose, thirty to ninety grains (2–6 Gm.).

Off. Prep.—Fluidextractum Chimaphilæ, *N. F.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

CHIONANTHUS. N. F.

CHIONANTHUS Chionanth. [Fringe Tree Bark]

"Chionanthus is the dried bark of the root of *Chionanthus virginica* Linné (Fam. *Oleaceæ*). Chionanthus contains not more than 5 per cent. of wood and other foreign organic matter. It yields to 70 per cent. alcohol not less than 25 per cent. of non-volatile alcoholic extractive." *N. F.*

Old Man's Beard, Poison Ash, Flowering Ash, Shavings Tree.

Chionanthus virginica is a low, deciduous tree indigenous to the Southern United States and extending north into Pennsylvania and New Jersey. It bears opposite, petiolate, ovate to obovate-lanceolate leaves and drooping panicles of white flowers. Its fruit is an ovoid, purple drupe. The commercial supplies of the drug come chiefly from Virginia and North Carolina.

Description and Physical Properties.—"*Unground Chionanthus.*—Usually in transversely curved pieces, occasionally in single quills from 1 to 10 cm. long; bark from 2 to 10 mm. thick; heavy, some pieces of the whole drug sinking when thrown into water; outer surface usually reddish brown, occasionally grayish brown, with few transverse wrinkles; scaly, roughened by shallow pits and ridges, whitish cork patches and root-scars; inner surface yellowish brown, more or less striate and undulate; fracture short, hard, and coarsely granular, the broken surface of a light yellowish-white color. Odor characteristic; taste bitter.

"*Structure.*—A thin outer bark of a corky layer and a zone of tangentially elongated cells; middle bark very thick, composed chiefly of thin-walled parenchyma, a few groups of scattered stone cells and occasional bundles of fibers; inner bark of small parenchyma cells, nearly straight tapering medullary rays which penetrate to the middle bark, a few groups of fibers and small sieve groups; parenchyma cells filled with small prismatic crystals of starch grains.

"*Powdered Chionanthus.*—Light brown; exhibits somewhat rounded, simple or 2- to 4-compound starch grains, the individual grains mostly 0.003 to 0.020 mm. in diameter, occasionally up to 0.25 mm. in diameter; numerous stone cells up to 0.115 mm. in length and 0.085 mm. in diameter, in groups and isolated, the walls thick, non-striated, strongly lignified and with simple and branching pores; few short fibers up to 0.200 mm. in length and 0.045 mm. in diameter, with blunt or truncate ends and lignified, lamellated walls with simple pores; numerous resin masses; few fragments consisting of light brown, thin-walled cork cells; parenchyma tissue, many of the cells with small prismatic crystals, a few with starch grains." *N. F.*

In the bark of this plant a saponin was found by R. S. Justice (*A. J. P.*, xlvii, 195), but not by W. von Schulz, who, however (*Ph. Z. R.*, 1893, 579), detected a glucoside.

Uses.—Chionanthus by some is supposed to have special relations towards the liver and has been used in the treatment of *catarrhal jaundice* and *portal congestion* and allied conditions.

Dose, one-half to one drachm (2–4 Gm.).

Off. Prep.—Fluidextractum Chionanthi, *N. F.*

CHIRATA. N. F., Br.

CHIRATA Chirat.

"Chirata is the dried plant of *Swertia Chirayita* (Roxburgh) Lyons (Fam. *Gentianaceæ*). Chirata contains not more than 3 per cent. of foreign organic matter." *N. F.* "Chiretta is the plant, Swertia Chirata, *Buch.-Ham.*, collected when in flower, and dried." *Br.*

East Indian Balmony; Chirayta; Chirette, *Fr.*; Chiretta, Ostindischer Enzian, *G.*

According to Lloyd, this drug has long been held in esteem by the Hindoos. It first attracted attention in England in 1829 and was introduced into the Edinburgh Pharmacopœia in 1839.

Swertia Chirayita (Roxb.) Hamilton (*Ophelia Chirata* Griesbach) is an annual plant, about three feet high, with a branching oblique root, and an erect, smooth, slightly winged branching stem, and furnished with opposite, lanceolate, very acute, entire, smooth, three or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are unilocular. The plant is a native of Nepaul and other parts of Northern India. The whole of it is gathered when the flowers are well advanced. Various dried gentianaceous plants occur as adulterants or substitutes of chirata; the most important of these is the *Swertia* (*Ophelia*) *angustifolia* Buch.-Ham. It yields the *Paharee* or *Hill chirata*, which is distinguished by its inferior bitterness, and its rectangular, winged stems, whose section presents a thick woody ring and a center nearly or entirely hollow, with only traces of pith. A false chirata, which resembles the official variety in having a well developed pith, but which is completely lacking in bitterness, is affirmed to be the product of *S. alata* Royle. (*P. J.*, xvii, 903.) Under the name of *Indian chirata*, the dried plant of the *Andrographis paniculata* Nees has appeared in the London market; it resembles much more closely recently dried broom tops than the true chirata. All of the above are readily distinguished from true chirata by their lack of bitterness.

The dried plant is imported into Europe in bundles, consisting mainly of the stems, with portions of the root attached. The stems contain a yellowish pith.

Description and Physical Properties.—"*Unground Chirata.*—Smooth; root simple, about 7 mm. thick near the crown; stem about 1 M. in length, externally yellowish or purplish brown, cylindrical near the base, quadrangular and slightly winged above, with numerous opposite, ascending branches; wood yellowish, thin, enclosing usually a large yellowish easily separable pith; leaves opposite, sessile, ovate-lanceolate, entire, five-nerved, up to 6 cm. long; flowers numerous, panicled, small, with a four-lobed calyx and corolla; capsule ovoid, acute, one-celled, many seeded. Odor slight; taste intensely bitter.

"*Powdered Chirata.*—Dark yellow or brownish; tracheæ numerous, spiral, scalariform or with simple pores, and frequently associated with lignified fibers; abundant pith parenchyma cells with lignified walls and simple pores; fragments of epidermis with stomata, the latter broadly elliptical and up to 0.045 mm. in length; occasionally whole seed about 0.400 mm. long or fragments of seed coat, with small, rather thick and wavy-walled epidermal cells; ellipsoidal pollen grains, smooth and up to 0.030 mm. in length; a few elongated cells with yellowish brown resin and tannin masses." *N. F.*

"Stem about one metre long, smooth, brown, or purplish-brown, slightly winged and much branched above, rounded below and containing a large, continuous, easily separable pith. Root oblique. Branches slender, elongated, decussate. Leaves opposite, ovate, glabrous, entire, usually with three to seven lateral veins. Flowers small, numerous, panicled. Fruits superior, bicarpellary, unilocular. No odor; taste extremely bitter." *Br.*

Flückiger and Höhn found in chiretta: sugar, wax, chlorophyll, soft resin, tannin, an acid which they name *ophelic,* possessing the formula $C_{13}H_{20}O_{10}$, and a peculiar bitter substance denominated *chiratin,* $C_{26}H_{48}O_{15}$. The acid is syrupy, deliquescent, yellowish-brown, at first slightly sour, afterwards intensely bitter. It is soluble in water, with some turbidness, probably owing to resin mixed with it, and completely soluble in alcohol, or a mixture of this with ether. It decomposes certain salts, and forms amorphous compounds with acids. Chiratin—which occurs in smaller amount—is a yellow, hygroscopic powder, difficultly crystallizable, very bitter, sparingly soluble in cold water, more so in hot water, and readily dissolved by alcohol and ether. It is neutral to test paper, and yields a copious precipitate with tannic acid. By the action of acids, chiratin is separated into ophelic acid, and a yellowish-brown, amorphous substance, bitter, scarcely soluble in water, readily soluble in alcohol, and not reducing copper solutions, as the ophelic acid does. Höhn gives it the formula $C_{13}H_{24}O_3$, and names it *chiratogenin.*

Uses.—Chirata has long been used in India. It has been introduced into Europe, and appears to be highly esteemed, but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the family of *Gentianaceæ.* (See *Gentiana.*) Like these, in over-doses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. It has been used in *dyspepsia,* and in the *debility* of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been employed in *intermittents* and *remittents,* combined with the seeds of *Guilandina Bonducella* L. It may be given in powder, infusion, tincture, or fluidextract.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Infusum Chiratæ, *Br.;* Tinctura Chiratæ, *Br.;* Fluidextractum Chiratæ, *N. F.*

CHLORAL FORMAMIDUM. Br.

CHLORAL FORMAMIDE

"Chloral Formamide, $C_3H_4Cl_3NO_2$, may be obtained by the direct combination of formamide with anhydrous chloral. Should be preserved in amber-colored bottles." *Br.*

Chloralamide; Chloralum formamidatum, *P. G.;* Chloralformamid, *G.*

Properties.—Chloralformamide is officially described in the Br. Pharm. as in "colorless lustrous crystals. No odor; taste slightly bitter. Soluble in 21 parts of *water;* very soluble in *alcohol* (90 per cent.), the solution being neutral to *litmus;* very soluble in *ether;* slowly soluble in 12 parts of *glycerin.* Melting point 114° to 115° C.; decomposes at a higher temperature. Hydrolyses in aqueous solution at 60° C., yielding chloral hydrate and formamide. Unaffected by dilute acids, but decomposed when warmed with *solution of sodium hydroxide,* chloroform separating and ammonia and sodium formate being produced. Heated with free access of air it volatilises completely without the evolution of inflammable vapors (absence of certain organic impurities). Its solution in *alcohol* (90 per cent.) is not immediately altered in appearance by *solution of silver nitrate* (absence of certain decomposition products)." *Br.*

Chloralimide, $CCl_3.CH{-}NH$, should not be confounded with chloral*a*mide. Chloralimide is in colorless, inodorous, and insipid, long crystalline needles; melting at about 166° C., insoluble in water; readily soluble in alcohol, in ether, in chloroform, and in oils. Concerning its physiological action we have no certain knowledge; it is asserted to be hypnotic in doses of from fifteen to sixty grains (1–3.9 Gm.).

Uses.—Locally, chloralformamide is scarcely at all irritant, and when taken internally is quickly absorbed and is eliminated chiefly as urochloralic acid. When given to the lower animals, it produces lethargy, sleep, muscular relaxation, arrested respiration, followed by coma, failing respiration, and if the dose has been sufficient, death by centric respiratory paralysis. As shown by the experiments of H. C. Wood and Cerna, subsequently confirmed by various observers, its influence upon the circulation and the spinal cord is extremely feeble, and it has no perceptible effect upon the nerve trunks and the muscles. As an hynotic it resembles hydrated chloral, but its action is more slowly developed and is less positive. Confusion, giddiness and headache are the only unpleasant effects following its use, and they rarely occur.

Dose, fifteen to forty-five grains (0.9–3.0 Gm.), half an hour before the desired time of sleep.

CHLORAL HYDRAS. U. S., Br.

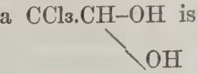
CHLORAL HYDRATE Chloral. Hydrat.

"Chloral Hydrate contains not less than 99.5 per cent. of $CCl_3CHO.H_2O$." *U. S.* "Chloral Hydrate, $C_2Cl_3H_3O_2$, may be obtained by the addition of water to the liquid chloral, C_2Cl_3HO, produced by the action of dry chlorine gas on ethylic alcohol." *Br.*

Chloralum Hydratum, *U. S. IX;* Hydrated Chloral; Trichloraldehyd Hydrate, Trichlorethylidene Glycol; Hydrous Chloral; Chloral Hydraté, *Fr.;* Hydrate de Chloral, *Fr. Cod.;* Chloralum Hydratum, *P. G.;* Chloral Hydrat, *G.;* Cloralio idrato, *It.;* Hidrato de cloral, *Sp.*

Though discovered by Liebig in 1832, it was not until 1869 that its remedial properties were first made known by their discoverer, Otto Liebreich of Berlin; in 1878 the consumption of chloral was estimated at one ton daily in England and America alone; and, although not used now to this extent, it is still largely employed.

Anhydrous Chloral.—In preparing anhydrous chloral, the simple method originally employed by Liebig, of acting directly on alcohol by chlorine, is generally preferred, even, we believe, by the larger manufacturers. This first forms chloral alcoholate which is treated with sulphuric acid to convert it into chloral. It is subsequently rectified by distillation over calcium carbonate and finally hydrated by mixing with molecular proportions of water and allowing it to crystallize. The action of chlorine upon alcohol is said to be aided by the presence of "chlorine carriers," such as iodine, ferric chloride, thallium chloride, etc. The formula of anhydrous chloral is C_2Cl_3HO; in other words, aldehyde, C_2H_4O, in which 3 atoms of hydrogen have been replaced by 3 atoms of chlorine. The name of chloral was derived from the *chlor*ine and *al*cohol from which it is formed. The *anhydrous chloral* thus formed is a colorless liquid, of penetrating disagreeable odor, of little taste, of the sp. gr. 1.502, and boiling at 94° C. It is soluble in ether or chloroform without change. According to A. Trillat, in the formation of chloral from alcohol, the latter is first changed by the action of the chlorine into aldehyde; this unites with alcohol to form acetal, which is changed successively into mono-, di-, and trichloracetal; the action of hydrochloric acid decomposes this latter with the formation of chloral alcoholate and ethyl chloride; sulphuric acid decomposes the alcoholate, liberating chloral, which then is made to combine with water to form the crystalline hydrated chloral. (*Bulletin,* 1897, 17, 230.) As the union of hydrated chloral with water develops heat, it is supposed to be more than the formation of a hydrate, and the formula $\mathrm{CCl_3.CH}\begin{array}{l}-\mathrm{OH}\\ \diagdown\mathrm{OH}\end{array}$ is assigned to the resulting compound. It does not show all the reactions of an aldehyde, as, for example, the red color of a magenta solution that has been decolorized with sulphurous acid, is not restored by it.



Meta-chloral.—By continued contact of anhydrous chloral and concentrated sulphuric acid, a change is effected in the chloral, by which it becomes a solid insoluble in water, which is designated as *insoluble chloral,* or *meta-chloral.* It is tasteless, of a white color resembling porcelain, and insoluble in alcohol and ether. Its formula is $C_6H_3Cl_9O_3$, being formed by the union of three molecules of chloral. It is stated that when perfectly pure, chloral does not become polymerized; the change is also said to be prevented by the addition of a little chloroform. When heated to 180° C., meta-chloral distils with reversion to liquid chloral. (Allen, *Com. Org. Anal.,* 2d ed., i, p. 171.)

Chloral Alcoholate.—A compound obtained by Roussin, which he announced as pure hydrated chloral, was found by Personne to contain no water, but to be in fact a compound of alcohol and chloral, and is now known by the name of *chloral alcoholate,* C_2HCl_3O,C_2H_6O. It results directly from the action of absolute alcohol on anhydrous chloral, and is now known to be formed as a stage in the manufacture of chloral from alcohol. As it is very likely to be confounded with hydrated chloral, the following points of difference should be noted. It forms white crystals melting at 46° C., and boils at 113.5° C., while hydrated chloral crystals melt at 58° C. and boil at 97.5° C.; chloral alcoholate melts without complete solution when warmed with two volumes of water, and, on cooling, congeals below the surface of the water, white hydrated chloral is soluble in one and one-half times its weight of water; chloral alcoholate, gently heated with nitric acid of 1.2 sp. gr., is violently attacked, while hydrated chloral is scarcely acted on; chloral alcoholate, when heated on platinum foil, inflames readily, while hydrated chloral scarcely burns. (Allen, *Com. Org. Anal.,* 2d ed., i, p. 172.)

The three related products, *anhydrous chloral,* polymeric *meta-chloral,* and *alcoholate,* described above, have been more or less introduced into the European markets, and have required some notice to prevent them from being confounded with hydrated chloral, which is alone official. The following observations will be confined to this last compound, and the reader will note that whether the simple term chloral, or the exact designation, hydrated chloral, is used, the same substance is intended.

Chloral hydrate is obtained by simply mixing anhydrous chloral with water. Acicular crystals soon form, which result from the union of a molecule each of the chloral and water, constituting hydrated chloral. It occurs in commerce mainly in two forms; in distinct crystals, which is the official form, or in crystalline plates, about three lines in thickness, broken into small, irregular pieces, so as to be readily introduced into broad-mouthed bottles. These pieces, while retaining their tabular form, are somewhat translucent, but usually covered with a white powder, which somewhat conceals that property. This form is sometimes called "chloral crusts." It is the more common form and the cheaper; but the crystals are to be preferred, as their purity may be relied on. Guerin adds his testimony to the necessity for dispensing only hydrated chloral which has been recrystallized and which is in the form of distinct crystals. He examined many samples, and found acidity in the crust or cake variety, due, as he believes, to the formation of hydrochloric and formic acids, produced by the action of water retained in the cake during the manufacture, and this remaining in contact with the crystals excites decomposition.

Hydrated chloral is white, possessing a peculiar pungent odor, and an acrid pungent taste. Exposed to the air it very slowly volatilizes, and, like camphor, when enclosed in a bottle, covers the interior surface with numerous minute crystals. If the boiling point be under 95° C., it indicates an under-hydrated preparation; if above 98° C., an over-hydrated one. The pure hydrated chloral does not take fire when heated, but evaporates without residue. With the aid of heat, its solution may be effected readily in chloroform; and the solution, on cooling, deposits it in beautiful crystals, which are generally needle-shaped, while those deposited from a solution in carbon disulphide are prisms. The aqueous solution is prone to decomposition, with the development of molds. Hydrated chloral should not, therefore, be kept long in this state.

It is neutral or, according to E. Schering, slightly acid when perfectly pure. When equal parts of hydrated chloral in crystals and of camphor in small fragments are shaken together in a bottle, and allowed to stand, they liquefy, forming a clear solution. When hydrated chloral and sulphuric acid are mixed, the temperature is greatly reduced. A solution of hydrated chloral dissolves morphine, quinine, and most of the vegetable alkaloids. When ammonium sulphide is added to an aqueous solution of hydrated chloral, the mixture rapidly turns yellow, and, after passing through several shades of color, finally becomes dark brown. From this liquid diluted sulphuric acid throws down a bulky brown precipitate. This, purified from precipitated sulphur and dried, is a light-brown powder of the composition $C_{18}H_{24}S_{13}N_4O_6$. Hydrogen sulphide gas forms a sulphydrate by its action on hydrated chloral. These reactions are important, as the detection of metallic poisons in toxicological cases by hydrogen sulphide has been complicated by the presence of hydrated chloral. A still more important chemical reaction of hydrated chloral is that which takes place when the hydrated, or either of its other forms, is acted upon by an alkali. Chloroform is developed, and along with it a formate of the alkali employed. Thus, in a strong solution of potassium hydroxide, put a pinch of powdered hydrated chloral, and almost instantly the odor of chloroform becomes perceptible, and some oil-like globules of chloroform may be seen at the bottom of the vessel. The reaction is as follows:

$$\underset{\text{Hydrated chloral}}{C_2HCl_3O.H_2O} + \underset{\text{potassium hydroxide}}{KOH} = \underset{\text{chloroform}}{CHCl_3} + \underset{\text{potassium formate}}{CHO.OK} + \underset{\text{water}}{H_2O}$$

Description and Physical Properties.—"Colorless, transparent crystals, having an aromatic, penetrating, and slightly acrid odor, and a slightly bitter, caustic taste. It slowly volatilizes when exposed to the air. One Gm. of Chloral Hydrate is soluble in 0.25 cc. of water, 1.3 cc. of alcohol, 2 cc. of chloroform, and in 1.5 cc. of ether, at 25° C. It is very soluble in olive oil and freely soluble in oil of turpentine. Chloral Hydrate is decomposed by caustic alkalies, alkali earths, and ammonia, chloroform and a formate of the base being produced. When warmed with a few drops of aniline and sodium hydroxide T.S., the intensely disagreeable odor of phenylisocyanide is developed.

"Ash: not more than 0.05 per cent. An alcoholic solution of Chloral Hydrate (1 in 20) does not at once redden moistened blue litmus paper, nor does it at once become opalescent on the addition of a few drops of silver nitrate T.S. (*chloride*). Shake about 0.5 Gm. of Chloral Hydrate, at intervals of five minutes during one hour, with 5 cc. of sulphuric acid in a glass-stoppered cylinder, which has previously been rinsed with sulphuric acid: the acid remains colorless or very nearly so when viewed transversely in a tube of about 20 mm. diameter (*readily carbonizable substances*). Gently ignite 2 Gm. of Chloral Hydrate: no inflammable vapors are evolved (*difference from chloral alcoholate*).

"Preserve in tightly stoppered bottles, in a cool place, protected from light." *U. S.*

"In colorless, non-deliquescent, monoclinic plates. Pungent, but not acrid odor; taste pungent and rather bitter. Soluble in less than 1 part of *water, alcohol* (90 per cent.), or *ether,* and in 3 parts of *chloroform.* Aqueous solution neutral or only slightly acid to *litmus.* Melting point 49° to 53° C.; at a slightly higher temperature it volatilises without residue. Decomposed by alkalies with liberation of chloroform. A solution in *chloroform,* shaken with *sulphuric acid,* imparts no color to the acid (absence of certain organic impurities). When 1 gramme of Chloral Hydrate is warmed with 6 millilitres of *water* and 0.5 millilitre of *solution of sodium hydroxide,* the mixture filtered, sufficient *N/10 solution of iodine* added to impart a deep brown color, and the whole set aside for an hour, no yelow crystalline perecipitate is produced (absence of chloral alcoholate). Its aqueous solution yields no precipitate with *solution of silver nitrate* (absence of free chlorides.)" *Br.*

The most delicate test for the presence of chloral alcoholate in hydrated chloral is said to be that with nitric acid. When 1 cc. of nitric acid (1.38 sp. gr.) is poured over 1 Gm.

of hydrated chloral a yellow color should not appear within 10 minutes, even if the mixture be warmed. (*A. J. P.*, 1894, 191.) For other tests for hydrated chloral by Jaworowski, the reader is referred to *Ph. Z. R.*, 1894, 373.

Assay.—"Dissolve about 4 Gm. of Chloral Hydrate, accurately weighed, in 10 cc. of distilled water, add 30 cc. of normal sodium hydroxide, and allow the mixture to stand for two minutes. Add phenolphthalein T.S., and determine the residual alkali at once by titration with normal sulphuric acid. Each cc. of normal sodium hydroxide corresponds to 0.1654 Gm. of $CCl_3CHO.H_2O$." *U. S.*

Chloral hydrate when triturated with phenol, camphor and other organic compounds forms eutectics which liquefy. In aqueous solution it is incompatible with alkalies which decompose it with the production of chloroform. Hydroalcoholic solutions in the presence of bromides or other saline ingredients frequently show a separation into two layers, the upper of which contains part of the alcohol and all of the chloral.

Uses.—The physiological action of hydrated chloral may be summed up as follows:—Its dominant effect is to depress the centers of consciousness, the soundness of the sleep produced being proportional to the quantity ingested. In somewhat larger doses it is depressant to the motor side of the spinal cord and respiratory center but the sensory apparatus is unaffected except after poisonous doses. In full dose it tends to lower blood pressure probably chiefly through an action upon the vasomotor center, although after large quantities there is a direct depressant influence upon the heart muscle. In poisonous doses it produces profound coma with anesthesia. After fatal quantities death is generally due to stoppage of the respiration through paralysis of the nerve centers, although sometimes due to sudden heart failure. Chloral has little effect on the secretions, although it is stated to somewhat increase the flow of urine. It escapes from the body through the kidneys, probably in part unchanged, although partially in the form of urochloralic acid. This latter body has the property of reducing Fehling's solution. The theory of Liebreich which led to the introduction of this drug into medicine, that it was decomposed by the alkalies of the body with the gradual liberation of chloroform, has been abundantly disproven.

Hydrated chloral is used internally in medicine as a somnifacient, as an anticonvulsant, and externally as a local anesthetic, disinfectant and deodorizer. For the relief of *insomnia* not caused by pain it is one of the most certain hypnotics which we possess and is therefore especially employed in the more obstinate forms of sleeplessness such as in *delirium tremens* and certain types of *insanity*. Its action is very prompt, sleep generally beginning within fifteen minutes or half an hour after its oral administration. The effects, however, do not usually last over three or four hours. When the wakefulness is caused by pain it is greatly inferior to the opiates but even here is often of service as an adjuvant. In cases of circulatory weakness it should be used always with great caution if at all, on account of its liability to depress the heart. As a somnifacient it is rarely necessary to give more than 15 grains at a dose.

It is also a remedy of great value in the treatment of various *convulsive disorders*. The determination whether or not to administer chloral in an individual case should be based upon the severity, rather than the type, of the convulsions, thus in *tetanus* and *strychnine poisoning* in which death may be the direct result of the spasm, it is one of the most frequently employed of remedies and justly so. On the other hand, in *epilepsy* ordinarily the convulsions are of little importance and, as the chloral does not lessen the convulsive tendency, it is not often of service; but in the condition known as *status epilepticus* it may prove of great value. It is also occasionally demanded in severe cases of *hysteria* and *chorea*. Certain local spasms, such as *laryngismus stridulus, asthma,* and *hiccough,* are at times greatly benefited by its employment.

Locally it is used to a large extent in combination with camphor or methyl salicylate as an anodyne and counter-irritant. Occasionally it is employed as a stimulating antiseptic to *wounds,* although its antibacterial powers are comparatively feeble. It has, however, been highly recommended by Siegmund (*Th. M.*, 1909) as a deodorizant in *gangrene of the lung* and various other malodorous conditions. It is said also that it is valuable for washing the hands after post-mortem examinations, acting both as a disinfectant and deodorizer. A two per cent. solution has been recommended by Quincke as a spray in *tonsillitis* and other inflamed conditions of the oral or nasal cavities.

Occasionally hydrated chloral in even not excessively large doses may produce very unpleasant symptoms, such as various skin lesions or circulatory failure. The latter may be very alarming and at least one case is recorded in which a single dose of thirty grains caused death. The common symptoms of chloral poisoning are: Deep sleep, passing into coma, the pupil, at first contracted, later dilates; the respirations fall in number; the pulse is weakened and rendered slower, but later may become rapid and irregular; the temperature is reduced; the muscular system is relaxed, and both sensibility and reflex action are diminished or completely abolished. The immediate cause of death is generally a paralytic arrest of respiration but in many cases there appears to have been a simultaneous arrest of the cardiac action, and it is very possible that fatal syncope may at times occur.

In the treatment, if the case be seen early, the stomach should be thoroughly evacuated by a rapidly acting emetic, as zinc sulphate, or the stomach tube, and atropine, strychnine, cocaine, and caffeine, employed as respiratory and circulatory stimulants; at the same time external heat should be applied to maintain the bodily temperature and efforts made to keep the patient awake. For the latter purposes, however, those measures which throw an added strain upon the heart, such as walking, must be sedulously avoided; the electric brush affords the most efficient and least injurious method of preventing sleep.

Hydrated chloral is best administered in solution with syrup of orange flowers, or some simple aromatic. Solutions of chloral hydrate easily undergo decomposition when exposed to light. Dissociation occurs with the formation of hydrochloric acid, trichloracetic acid and formic acid. Solutions of chloral hydrate, therefore, should be preserved in the dark. The French sometimes employ *chloral cream,* made of hydrated chloral 5 parts, water 15 parts, white sugar finely powdered 100 parts, flavored with mint, orange, or vanilla. One teaspoonful is equivalent to about 3 grains of hydrated chloral. This preparation keeps well, and the dose may be dissolved in a little water. *Chloral liniment* may be made by dissolving 6 parts of hydrated chloral in 30 parts of oil of sweet almonds. *Chloral ointment,* 6 parts hydrated chloral, 3 parts white wax, 27 parts lard; the lard and wax are melted at a gentle heat, the hydrated chloral added in powder and dissolved. *Chloral plaster,* to produce counter-irritant effects, is prepared by spreading powdered hydrated chloral on Burgundy pitch plaster; care should be taken to distribute it uniformly.

Dose, ten to thirty grains (0.65–2.0 Gm.).

CHLORAMINA. U. S.

CHLORAMINE Chloram. [Sodium Paratoluenesulphonchloramide, Chloramine - T]

"Chloramine [$C_6H_4(CH_3)(SO_2NNaCl).3H_2O$] contains not less than 11.5 per cent. and not more than 13 per cent. of active chlorine." *U. S.*

Chlorazene, Tolamine, Tochlorine.

This compound was first made by Chattaway in 1905 (*Tr. Chem. Soc.,* 1905, lxxxvii, p. 153) but its introduction as a medicine was due to the studies of Dr. Dakin in 1915, who suggested for it the name of chloramine. This name is somewhat unfortunate as it has been also applied to the substance NH_2Cl, which is used for very different purposes.

According to Eicher (*J. A. Ph. A.,* 1917, iii, p. 387), in aqueous solution it liberates NCl to which its disinfectant properties are attributable.

Chloramine is prepared from toluene as the starting point. This is first converted into toluene-para-sulphonic acid, the sodium salt of which, when treated with phosphorus pentachloride, yields toluene-para-sulphonic chloride. This compound, which is an abundant by-product in the manufacture of saccharin is sometimes used as the starting point. It is then converted into toluene-para-sulphonamide by treatment with ammonia under pressure. This is finally treated with sodium hypochlorite in the presence of an alkali, the chloramine being obtained from this solution by crystallization. It is twice recrystallized from hot water and finally dried at 35° to 40° C.

Description and Physical Properties.—"White or faintly yellow crystals or a crystalline powder, having a slight odor of chlorine. It slowly decomposes on exposure to air, losing chlorine. One Gm. of Chloramine is soluble in about 7 cc. of water at 25° C. and in about 2 cc. of boiling water. It is decomposed by alcohol, and is insoluble in benzene, chloroform, and ether. At about 95° to 100° C. Chloramine loses its water of crystallization without decomposition.

"An aqueous solution of Chloramine (1 in 20) is alkaline to litmus paper or phenolphthalein T.S. The addition of potassium iodide T.S. to an aqueous solution of Chloramine (1 in 20) causes the liberation of iodine, but bromine is not liberated from alkali bromides unless the mixture is acidulated with an acid (*difference from dichloramine*). Acids produce in an aqueous solution of Chloramine (1 in 20) a white turbidity or precipitate which redissolves in an excess of alkali hydroxide solutions. When strong mineral acids are used, chlorine is also liberated. On adding 2 cc. of sulphuric acid to 0.1 Gm. of Chloramine, chlorine is evolved but no appreciable darkening occurs (*readily carbonizable substances*).

"**Assay.**—Dissolve about 0.5 Gm. of Chloramine, accurately weighed, in 50 cc. of water, add 5 cc. of potassium iodide T.S. and 5 cc. of acetic acid, and allow the mixture to stand in a glass-stoppered bottle for ten minutes. Titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.001773 Gm. of active chlorine.

"Preserve in well-closed containers, protected from light." *U. S.*

Bebie (*J. A. Ph. A.,* 1920, ix, 974) found that solutions of chloramine—provided the latter be pure—showed no perceptible deterioration after six months' storage.

Uses.—Chloramine was brought to the notice of the medical profession by Dakin in 1915 as a surgical disinfectant possessing the advantages over sodium hypochlorite of being more stable in solution and less irritant to the tissues (*B. M. J.,* Aug. 25, 1915 and Jan. 29, 1916). It is a powerful germicide; according to Hamilton, tested by the Hygienic Laboratory method it showed a phenol coefficient of about 50, one part in 2000 being sufficient to destroy the bacillus typhosus in two and one-half minutes. But Tilley (*Journ. Agricul. Res.,* 1920, xx, 85) found that in the presence of organic matter (blood serum) its strength was greatly reduced, a 1 to 500 solution requiring 2 hours to kill typhoid bacilli. Tilley also tested chloramine against other bacteria and while in most cases he found it to approach mercuric chloride in power it was comparatively inefficient against anthrax spores and against the tubercle bacillus; a 1 per cent. chloramine solution failed to kill the tuberculosis germ in 10 minutes and required 24 hours to destroy anthrax spores. In contrast to these results Vincent (*J. Ex. M.*, 1917, xxvi, 83) found that 0.2 per cent. of chloramine was not only not germicidal to the staphylococcus but was not even a complete antiseptic; it required 0.22 per cent. to certainly inhibit the growth of these bacteria.

Taylor and Austin (*J. Ex. M.*, 1918, xxvii, p. 635) and Fantus and Smith (*J. P. Ex. T.*, xiv, p. 259) have both found that when introduced into the blood stream, chloramine is a violent systemic poison. According to the former investigators it ranks in toxicity close to mercuric chloride, being fatal to mice in the proportions of 0.01 Gm. per kilo body weight; Fantus and Smith found the fatal dose for the rabbit to be 0.025 Gm. per kilo. It is a depressant to the whole central nervous system.

The value of chloramine in infected *wounds*, which was so abundantly proven in military surgery during the recent great war, has since been confirmed by civilian surgeons. Although its action appears to depend, like that of the hypochlorites, on the liberation of chlorine its range of usefulness is slightly different from that of the inorganic chlorinated compounds. In ordinary wounds, because of its lower irritating qualities, it is usually preferable to the alkaline hypochlorites, but where there is much necrotic tissue, chloramine, as has been shown by Taylor and Austin, has a distinctly lesser power of dissolving this undesirable detritus. It is mostly employed in dilute solutions for irrigating deep wounds, but Carrel and Hartmann (*J. Ex. M.*, 1917, xxvi, p. 95) assert that by packing wounds with a paste, devised by Daufresne, it is possible to render them completely sterile. The basis of this paste contains 8.6 per cent. of neutral sodium stearate in distilled water, and is usually made to contain from ½ to 1 per cent. of chloramine; it should be freshly prepared as it loses its active ingredient at the rate of about 10 per cent. a month.

Chloramine may also be employed as an antiseptic mouth wash and for irrigation of the bladder, uterus, and other internal cavities. It is not suitable for a gastric antiseptic because it is decomposed by the secretions of the stomach, but Carnot and Bondouy (*A. J. P.*, 1919, xvi, 474) state that if protected from the action of gastric juices it may be used advantageously as an intestinal antiseptic. As a surgical disinfectant it may be used in strengths of from 0.5 to 4 per cent. It should not be confused with dichloramine.

CHLOROFORMUM. U. S., Br.

CHLOROFORM Chlorof.

"Chloroform contains not less than 99 per cent. and not more than 99.5 per cent. of $CHCl_3$, the remainder consisting of alcohol. *Caution—Care should be taken not to vaporize Chloroform in the presence of a naked flame, because of the production of noxious gases.*" *U. S.*

"Chloroform is trichlormethane, $CHCl_3$ to which 2 per cent. of Absolute Alcohol has been added. It may be obtained from ethylic alcohol, industrial methylated spirit, or acetone, by heating with chlorinated lime, slaked lime, and distilled water, and subsequent purification. Should be kept cool and in a dark place." *Br.*

Trichlormethane, Methenyl Trichloride; Chloroformum Purificatum, *U. S.* 1880; Formylum Trichloratum; Chloroforme Anesthésique, *Fr. Cod.*; Chloroformium pro Narcosi, *P. G.*; Reines Chloroform, Chloroform, *G.*; Cloroformio, *It.*; Clorido Formico, Cloroformo, *Sp.*

Chloroform is tri-chlor-methane and may be produced by the interaction of chlorine and methane although the process is not economically practicable.

It was at first made from alcohol by the action of chlorinated lime, but is now made on the large scale, by the distillation of acetone with chlorinated lime; indeed, this process has entirely replaced the manufacture from alcohol. Liebig, as long ago as 1832, described the reaction, but it was thought to be not adapted for commercial use until 1882. To get a satisfactory yield, a very pure acetone is necessary. When such acetone is taken, a yield of nearly or quite 200 per cent. of chloroform can be obtained. (For an account of the methods of purifying the acetone and distilling with chlorinated lime, see *A. J. P.*, 1889, p. 321.) In July, 1885, a patent was taken out by G. Michaelis of Albany, for the manufacture of chloroform from the liquid products resulting from the decomposition of crude acetates at high temperatures. These liquid products are acetone and other higher ketones. Pure methyl alcohol does not yield chloroform. The erroneous statements on this point are probably due to the fact that commercial wood spirit contains a large percentage of acetone.

E. R. Squibb preferred acetic acid to the acetates in the intermediate step of making acetone, thus avoiding impurities likely to be present in acetates; he believed that the grant of a patent for "acetone chloroform" was deficient in equity. (*Ephem.*, 1896, 1743 to 1757.)

Chloroform has been prepared electrolytically but the method has been criticized as yielding a product of unsatisfactory quality.

Chloroform is also made by the Besson process which consists in passing chlorine into ethyl alcohol until the liquid has a specific gravity of 1.32, a mixture of bleaching powder and milk of lime is added and distillation conducted. The yield is said to be over 95 grammes of chloroform for each 100 grammes of alcohol employed. (*Revue Scientifique*, Feb., 1893.)

Carbon tetrachloride (CCl_4) has also been proposed (1896) as a source of chloroform, and as this is now made cheaply on a large scale, the process may come into use. By the action of hydrochloric acid and zinc, hydrogen is liberated and attacks the carbon tetrachloride, forming chloroform and hydrochloric acid,

$$CCl_4 + H_2 = CHCl_3 + HCl$$

As hydrochloric acid is a product of the reaction, fresh quantities of zinc are attacked, and a new liberation of chloroform follows.

Pure chloroform will not keep, but after some time becomes so loaded with decomposition products as to be altogether unfit for respiration. Squibb showed, in 1857, that it is rendered more stable by the addition of a small proportion of alcohol. He recommended adding alcohol in the proportion of ten drops to each fluidounce of good chloroform of maximum density. This recommendation has been adopted by both the U. S. and Br., and explains the addition of alcohol before distillation. Even preserved in this manner, by the addition of alcohol, chloroform will undergo deterioration if kept for long periods. Gregory also attributes the tendency to decomposition to its purity, and to the action of sunlight; having found that those portions which he had purified with the greatest care were soonest decomposed under the influence of light. For methods of preserving chloroform by the use of sulphur, hypophosphorus acid, etc., see *P. J.*, 1895, 261; also 1896, 249.

The intermediate formation of hydrated chloral as a result of the reaction between alcohol and chlorinated lime suggested the preparation of chloroform from hydrated chloral. The advantages which were anticipated from decomposing pure hydrated chloral with alkalies have not altogether been realized, for the product is much more expensive, and the claim of greater stability has not been sustained, as it requires just as much alcohol to preserve it as that made in the usual way.

History.—Chloroform was discovered by Samuel Guthrie of Sackett's Harbor, N. Y., in 1831, and about the same time by Soubeiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0.844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from potassium carbonate. (*Silliman's Journal,* 1832, xxi, p. 64 and xxii, p. 105.) Guthrie states that the substance which he had obtained, "distilled of sulphuric acid, has the specific gravity of 1.486, or a little greater, and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of potassium carbonate, it may then be regarded as *absolutely pure.*" It is thus evident that Guthrie obtained, in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression he called the substance, in his communications, *chloric ether,* one of the names by which *Dutch Liquid,* or *ethene dichloride,* is designated. Chloroform was used internally in *asthma* and other conditions as early as 1832 by Ives of New Haven, and subsequently in various conditions by several European physicians, but it was not until November, 1847, that Sir James Y. Simpson of Edinburgh brought it forward as a general anesthetic.

Description and Physical Properties.—"A clear, colorless, mobile liquid, having a characteristic, ethereal odor, and a burning, sweet taste. It is not inflammable, but its heated vapor burns with a green flame. Chloroform is soluble in 210 volumes of water. It is miscible with alcohol, ether, benzene, petroleum benzin, and with fixed or volatile oils. Specific gravity: 1.474 to 1.478 at 25° C. Chloroform boils at about 61° C., but is volatile even at lower temperatures.

"Evaporate 50 cc. of Chloroform in a platinum or porcelain dish on a water bath, and dry to constant weight at 100° C.: the weight of the residue does not exceed 0.001 Gm. Pour 20 cc. of Chloroform, in small portions, upon a piece of clean, odorless, filter paper, laid flat upon a warmed glass plate, and rock the plate from side to side, until the liquid is completely evaporated: no foreign odor becomes perceptible as the last portions disappear from the paper, and the paper remains odorless. Agitate 10 cc. of Chloroform with 25 cc. of distilled water, and allow the liquids to separate completely. The aqueous layer is neutral to litmus paper and separate portions of 10 cc. each are not affected by a few drops of silver nitrate T.S. (*chloride*), or colored blue by the addition of a few drops each of potassium iodide T.S. and starch T.S. (*free chlorine*). Transfer 40 cc. of Chloroform to a 50 cc. glass-stoppered cylinder of colorless glass, having an internal diameter of about 20 mm. and previously rinsed with sulphuric acid, add 4 cc. of colorless sulphuric acid, and shake the mixture vigorously for five minutes. Allow the liquids to separate completely, so that both are transparent: the Chloroform remains colorless, and the acid is colorless or nearly so, when viewed transversely in the cylinder (*substances decomposable by sulphuric acid*). Dilute 2 cc. of the sulphuric acid separated from the Chloroform in the preceding test with 5 cc. of distilled water: the liquid is colorless and clear, and while hot from the mixing emits but a faint, vinous or ethereal odor (*odorous decomposition products*). When further diluted with 10 cc. of distilled water, it remains clear, and is not affected within one minute by the addition of three drops of silver nitrate T.S. (*chlorinated decomposition products*).

"Preserve in well-stoppered bottles, in a cool place, protected from light. Protect Chloroform from contact with cork stoppers by covering them with tin foil or other suitable material." *U. S.*

"A colorless, volatile liquid. Characteristic odor; taste pungent, sweet. Specific gravity 1.483 to 1.487. Does not begin to boil below 60° C. On allowing 10 millilitres to evaporate from a large piece of filter paper placed on a warm plate, no extraneous odor is perceptible at any stage of the evaporation. *Water* which has been shaken for five minutes with half its volume of Chloroform, and separated from the undissolved Chloroform, is neutral to *litmus* (absence of acid), does not give any color with 1 millilitre of *solution of cadmium iodide* and 2 drops of *mucilage of starch* (absence of free chlorine), and yields not more than a very slight opalescence with 4 drops of *solution of silver nitrate* (absence of chlorides). After shaking *sulphuric acid* with twice its volume of Chloroform for five minutes, and setting aside for fifteen minutes, both the acid and the Chloroform are nearly colorless. 2 millilitres taken from the layer of *sulphuric acid,* and diluted with 5 millilitres of *water,* remain very nearly colorless, and have a pleasant odor. When this acid liquid is further diluted with 10 millilitres of *water,* and stirred with a glass rod, it is transparent and colorless, and the addition of 4 drops of *solution of silver nitrate* causes not more than a slightly diminished transparency. *Water* which has been shaken with half its volume of Chloroform, previously treated with *sulphuric acid* as described above, yields not more than a slightly diminished transparency with *solution of silver nitrate.* Evaporates without residue." *Br.*

Besnou gives the densities of various mixtures of alcohol and the purest commercial chloroform at 4.5° C. as follows:

Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.	Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.
1.4945	100.0	0.0	1.4772	97.5	2.5
1.4908	99.5	0.5	1.4602	95.0	5.0
1.4874	99.0	1.0	1.4262	90.0	10.0
1.4840	98.5	1.5	1.4090	87.5	12.5

The alcoholic solution, when moderately diluted with water, forms a sweetish, aromatic liquid of a very grateful taste. A strong alcoholic solution is decomposed by an abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water.

It is liable to decomposition by sunlight, or even diffused daylight; and hence the propriety of keeping it in bottles covered with dark paper, in a rather dark place. Chloroform has extensive solvent powers, being capable of dissolving camphor, caoutchouc, gutta-percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, many alkaloids, the fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly. As a general solvent, it has the advantage over ether of not being inflammable, the inflammability of the latter being the cause of frequent accidents.

When chloroform vapor, however, comes in contact with a naked flame the chloroform is dissociated with the liberation of irritating chlorine derivatives, hence the warning usually given against administering under such conditions.

Traces of hydrochloric acid in chloroform may be detected by adding a minute quantity of para-dimethylaminoazobenzene. A violet color is produced in the presence of free hydrochloric acid.

The addition of benzidine serves for the detection of phosgene which produces a turbidity or a precipitate, and of chlorine which first produces a red and finally a blue color. Fuming nitric acid, heated with chloroform to 100° C. in a closed tube for 120 hours, forms a new substance, *chloropicrine* (see *chlorpicrin,* Part II).

Uses.—Locally chloroform is actively irritant and somewhat anesthetic. When applied to the skin in ordinary manner it produces pain and redness and if evaporation be prevented will frequently blister. The pain is followed by a sensation of numbness.

Chloroform is actively antiseptic and even germicidal. A one per cent. solution is sufficient to kill most non-sporulating bacteria if the contact be sufficiently prolonged; but against spore-forming organisms it is of little avail. J. B. Barnes has found that in the proportions of 20 minims to the pint it prevents fermentation of such fluids as malt, milk or mucilage.

Taken into the stomach in doses of about five minims (0.3 cc.), it induces only gastric symptoms, chiefly due to its irritant properties; but when there is excessive flatulence, colic, or gastralgia, it not only causes an increased peristalsis and expulsion of any flatus present, but evinces a distinct local narcotic influence by quieting pain and spasm. Taken in doses of 1 to 2 fluidrachms (3.75–7.5 cc.), it produces a narcotism similar to that seen when it is administered in inhalation, the narcotism, however, developing and passing off much more slowly than in the latter case.

The action of chloroform upon the system like that of ether, is predominantly upon the central nervous system. The first portion to feel the effect of the drug is the higher cerebral centers. After larger quantities there is depression of the spinal cord, first of the sensory side and later of the motor tract, and finally paralysis of the medullary centres, especially the respiratory and vasomotor. It differs from ether not only in the power of its action but especially in the fact that it is directly depressant to the heart. A discussion of the relative advantages and disadvantages of these two great anesthetics would occupy too much space to be permissible here and the reader is referred for details to H. C. Wood, Jr.'s *Text-book of Pharmacology.* It may, however, be remarked that under ordinary circumstances chloroform, although more pleasant to take than ether, is much more dangerous.

Aside from its use in surgery chloroform is sometimes used to relieve severe *pain,* as in *neuralgia, gallstone colic,* and the like. It is also capable of relieving the asthmatic paroxysm. For these properties it is generally administered by inhalation but should only be employed with the greatest caution. Internally it is used as a carminative in *flatulent colic* and as a stimulant in combination with other drugs in the treatment of *serous diarrheas.* It has also been recommended as an anthelmintic, especially in the treatment of *hookworm,* but appears to be more dangerous than other equally efficient drugs. Externally it is very widely employed as a counter-irritant, especially in the form of the liniment. Langenbeck, of Berlin, prefers chloroform to tincture of iodine as an injection for the radical cure of *hydrocele.*

Chloroform ointment is made by adding twenty parts of chloroform to a mixture of ten parts of white wax and ninety parts of lard, previously melted together, and allowing the whole to cool. Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 60° C. In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by friction. *Syrup of chloroform* may be made by adding one fluidounce of spirit of chloroform to fifteen fluidounces of syrup.

When an overdose of chloroform is taken by the mouth, it is essential to empty the stomach by the pump or siphon tube, and then treat the case much as in serious narcosis from inhalation. In a case of suicide by swallowing chloroform in which death took place in about thirty-four hours, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested; but these morbid appearances are not constant.

Dose, of chloroform, five to fifteen minims (0.3–0.9 cc.).

CHONDRUS. N. F.

CHONDRUS Chondr. [Irish Moss, Carrageen]

"Chondrus is the dried bleached plant of *Chondrus Crispus* (Linné) Stackhouse or of *Gigartina Maruillosa* (Goodenough et Woodard) J. Agardh (Fam. *Gigartinaceae*). Chondrus contains not more than 2 per cent of foreign organic matter." *N. F.*

Caragahen, Fucus Crispus, Pigwrack, Killeen, Pearl Moss; Hen's Dulse; Carragheen; Carragaheen; *Fr. Cod.;* Mousse Marine perlée, *Fr.;* Carrageen, *P. G.;* Irländisches Moos, Perlmoos, Knorpeltang, *G.;* Fuco carageo, Musco d'Irlanda, Fuco crispo, *It.;* Caragaen, Musgo marino perlado, *Sp.*

Chondrus crispus grows upon rocks and stones on the coast of Europe, and is especially abundant on the southern and western coasts of Ireland, where it is collected. It is also a native of the United States, and is gathered largely on the coast of Massachusetts, below Boston, where it is partly torn from the rocks and partly collected from the beach, on which it is thrown up during storms. It is prepared for market by spreading it out to dry and bleach in the sun. For elaborate accounts of the plant, of its distribution on the sea coast of Massachusetts, and of the mode of gathering and curing, see *A. J. P.,* 1895, 596; 1899, 483. Henry Kraemer witnessed the methods pursued on the Massachusetts coast in the collection of Irish moss at Scituate, which appears to be a particularly favorable situation. The season for collection begins late in May and continues to September, June and July being the best months. The moss at present is only found on rocks that are from 15 to 20 feet below the tide, hence women no longer engage in its collection. The men go out in their sail boats or dories at half tide, come in at half flood. With their long rakes they scrape the moss off the rocks, collecting thus about 50 pounds to the boat, the total for the season at Scituate being about 10,000 pounds. The moss is spread out on the high beach for a week or so, the action of the sun and dew bleaching it. It is then enclosed in hogsheads, in which it is again saturated with sea water by rolling them in the marshes; after which it is again spread out and subjected to the bleaching process, this alternate treatment being repeated four or five times, until the product is of a yellowish or white color. The final drying is done in barns, where the moss is stored until it is packed in 100 lb.

barrels at the end of the season. In the course of this journey he had opportunity to observe the *Chondrus* growing and gathered in different localities along the coast, and found it to consist chiefly, if not entirely, of *Chondrus crispus.* While it is stated in Dr. Farlow's "The Marine Algæ of New England" that the closely resembling *Gigartina mamillosa* is common from Boston northward, Kraemer is inclined to believe that *Chrondus crispus* (L.) Lyngbye, is practically the only source of the American drug. (See *Proc. Penn. Pharm. Assoc.*, 1899, 113–116.) Tunmann (*Apoth. Zeit.*, 1909, pp. 91 and 151) has given an elaborate account of the morphology and composition of *Chondrus.*

Girgartina mamillosa Ag. resembles the true Irish moss, and, growing with it upon the rocks, may be gathered with it. It can, however, be at once distinguished by the numerous papillæ which cover the surface and margins of the fronds and bear the fruit (cystocarps). In chemical and medicinal properties it is probably identical with *C. crispus.*

The commercial supplies of Chondrus are chiefly obtained from Boston (Massachusetts), Nimes (France) and Dublin (Ireland).

Irish moss when collected is washed and dried. It is probably sometimes bleached by the use of potassium permanganate and sodium thiosulphate by the same process as that used for bleaching sponge. Schack was led to suspect this through discovering the presence of sulphurous acid in a German specimen. (*Ph. Ztg.*, 1886, p. 87.) The presence of arsenic has been determined in some commercial lots, being caused, no doubt, by the impurities in the sulphur used for bleaching Chondrus. Some "faked" samples have yielded as much as 35 per cent. of ash which contained a large quantity of calcium sulphate. The gelatinizing value of specimens of this kind is about 60 per cent. below normal. In the fresh state it is of a purplish color, but as found in the shops, is yelowish or yellowish-white, with occasionally purplish portions.

Description and Physical Properties.—"*Whole Chondrus.*—Entire plants matted together, consisting of a slender stalk from which arises a series of dichotomously branching, more or less flattened segments, emarginate or deeply cleft at the tips; from 5 to 15 cm. in length, and 1 to 10 mm. in width; yellowish-white; translucent, frequently coated with a calcareous deposit which effervesces with hydrochloric acid; sometimes with fruit bodies or sporangia embedded near the apex of the segments (in *C. crispus*) or with sporangia borne on short tuberculated projections or stalks, more or less scattered over the upper portion of the segments (in *G. mamillosa*); somewhat cartilaginous. Odor slight, seaweed-like; taste mucilaginous, saline.

"Boil one part of Chondrus for about ten minutes with 30 parts of water, replacing the water lost by evaporation; the strained liquid forms a thick jelly upon cooling. When softened in cold water, Chondrus becomes gelatinous and transparent, the thallus remaining nearly smooth and uniform and not swollen except slightly at the tips; a solution made by boiling 0.3 Gm. of the drug in 100 cc. of water and filtering gives no precipitate on the addition of tannic acid T.S. (absence of *gelatin*), and when cold does not give a blue color on the addition of iodine T.S. (absence of *starch*)." *N. F.*

It swells in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and the solution, if sufficiently concentrated, gelatinizes on cooling. Herberger found 79 per cent. of a mucilaginous substance resembling pectin, and 9.5 of mucus, with fatty matter, free acids, chlorides, etc.

This gum-like substance, which is known as *carrageenin,* is distinguished from acacia by affording, when dissolved in water, no precipitate with alcohol; from starch, by not becoming blue with tincture of iodine; from pectin, by yielding no precipitate with lead acetate and from mucic acid by the action of nitric acid. It is probably not a pure principle but a mixture of carbohydrate derivatives. According to Sebor (1900) it yields, when hydrolized, galactose, dextrose, levulose and salts of sulphuric acid. Muther and Tollens (1904) found also hydroxy-methylfurfuraldehyde. Blondeau in 1865 prepared a substance which he called *goemine* by boiling chondrus for several hours and precipitating the resulting mucilage with alcohol. *Fucusol* is an oily liquid, isomeric with furfural, which is obtained by boiling the seaweed with dilute sulphuric acid. Carrageenin has been used as a substitute for acacia under the name of "imitation gum Arabic"; it occurs in three forms, white, pale yellow and yellow. These differ from the true acacia not only in chemical properties, but in being much less adhesive (Federer, *Ph. Era*, 1887).

The ash of chondrus amounts to from 8 to 15 per cent. and contains traces of iodine. On oxidation with nitric acid the dry moss yields from 21.6 to 22.2 per cent. of mucic acid. There is present also about 7 per cent. of protein material. The mucilage of Irish moss has come into considerable use as an emulsifying agent. (*Proc. A. Ph. A.*, 1887; *A. J. P.*, 1888, 170.)

Uses.—Chondrus is nutritive, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, etc., are usually employed. It was formerly employed as a demulcent in *chronic pectoral affections, diarrhea,* and *disorders of the kidneys and bladder,* but is rarely so employed to-day. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavor. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction;

any unpleasant flavor that it may have acquired from the contact with foreign substances is thus removed.

Dose, four drachms (15.5 Gm.).

Off. Prep.—Mucilago Chondri, *N. F.*

CHROMII TRIOXIDUM. U. S. (Br.)

CHROMIUM TRIOXIDE Chrom. Triox. [Chromic Anhydride]

"Chromium Trioxide contains not less than 95 per cent. of CrO_3. *Caution—Chromium Trioxide should not be brought into intimate contact with organic substances, as serious explosions are liable to result.*" *U. S.* "Chromic Anhydride, CrO_3, may be obtained by the interaction of sulphuric acid and potassium bichromate. It should be preserved in well-stoppered bottles." *Br.*

Acidum Chromicum, *Br.,* Chromic Acid; Anhydrum Chromicum, Anhydride Chromique, *Fr. Cod.;* Chromic Acid, Acide Chromique Cristallisé, *Fr.;* Acidum Chromicum; *P. G.;* Chromsäure, *G.;* Anidride cromica, Acido cromico, *It.;* Acido cromico, *Sp.*

No method for this anhydride is official; it is usually prepared by decomposing potassium dichromate with sulphuric acid and crystallizing out the resultant chromic oxide. For details see *U. S. D.,* 20th ed., p. 329. According to Kebler there may also be found in commerce an impure "chromic acid" made by mixing a solution of sodium dichromate with sulphuric acid and drying the product; it sometimes contains 60 per cent. of acid sodium sulphate (*Am. Drug.,* 1901, 344). The requirements of the U. S. Pharmacopœia are that even traces of sulphuric acid shall be absent, and that the color of the crystals be not scarlet.

Description and Physical Properties.—"Small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic luster. It is odorless, and is deliquescent in moist air. Chromium Trioxide is destructive to animal and vegetable tissues. One Gm. of Chromium Trioxide is soluble in 0.6 cc. of water at 25° C. One Gm. is soluble in 0.5 cc. of boiling water. When Chromium Trioxide is brought into contact with organic solvents (*e.g.,* alcohol), decomposition takes place, sometimes with dangerous violence. When Chromium Trioxide is heated, it darkens and finally becomes black, but the color is restored on cooling. At about 190° C. it fuses to a reddish-brown liquid, which on cooling forms a dark red, brittle mass (often enclosing cavities filled with crystals), yielding a scarlet powder. Above 250° C. it begins to decompose into green chromic oxide and free oxygen, and after protracted heating leaves a residue of green chromic oxide.

"When Chromium Trioxide is warmed with hydrochloric acid, chlorine is evolved. Chromium Trioxide responds to the reaction's for chromates, page 441. A solution of 1 Gm. of Chromium Trioxide in 100 cc. of distilled water, previously acidulated with 3 cc. of hydrochloric acid, is not rendered turbid within one mnute on the addition of 1 cc. of barium chloride T.S. (*sulphuric acid*).

"Preserve in glass-stoppered bottles." *U. S.*

"Crimson acicular crystals, very deliquescent, inodorous, acting corrosively on the skin. Very soluble in *water* and in *ether.* Strongly heated it first melts and then evolves oxygen, leaving, after heating to redness, a green residue, which yields little or nothing to *water.* Warmed with *hydrochloric acid,* chlorine is evolved. In contact with relatively small proportions of *alcohol* (90 per cent.), *ether, glycerin,* or certain other organic substances, sudden combustion or explosion may ensue. When 4 grammes are dissolved in a mixture of 20 millilitres of *water* with 10 millilitres of *hydrochloric acid,* 5 millilitres of *solution of barium chloride* added and the mixture filtered, the filtrate yields no further precipitate on the addition of more of the reagent (limit of sulphates)." *Br.*

Chromium trioxide, at a heat above the melting point, gives off half its oxygen, and is converted into the green sesquioxide, Cr_2O_3. It is a powerful oxidizing and bleaching agent, and gives up its oxygen with great facility to organic matter. The oxidation of weaker alcohol is attended with the production of aldehyde, recognized by the odor, that of stronger alcohol, by inflaming.

"**Assay.**—Dissolve about 1 Gm. of Chromium Trioxide, accurately weighed in a stoppered weighing bottle, in sufficient distilled water to make 100 cc. Mix 15 cc. of this solution with 3 cc. of hydrochloric acid and 2 Gm. of potassium iodide in a glass-stoppered container, agitate the mixture, allow it to stand for five minutes, then dilute it with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003333 Gm. of CrO_3." *U. S.*

Uses.—In dilute solution chromium trioxide is a powerful coagulant of albumin and is therefore astringent. In more concentrated solution because of its oxidizing power it destroys all forms of tissue and is a rapid and powerful caustic. It is also an active germicide; according to Koch a 1 per cent. solution is sufficient to destroy anthrax spores after two days' exposure. By virtue of its oxidizing effect it destroys decaying organic matter, combining with and neutralizing the ammonia and decomposing hydrogen sulphide, thereby acting as a deodorizant.

As a caustic the liquid formed by the spontaneous deliquescence of the crystals may be used; it is most frequently applied by means of a glass rod.

Much care should be exercised in the use of this agent as it is a powerful poison both because of its local irritant effect and its systemic action. A single drop of the saturated solution taken internally has caused violent symptoms and fatal results have followed the too free external use of the drug. (See Shaw, *Virginia Med. Semi-monthly,* 1901, v.)

In dilute solution (5 per cent.) it is used as an antiseptic and astringent wash in *leucorrhea, ozena,* and *hyperidrosis.* In the Prussian army it has been found useful as a foot wash for preventing *sweating of the feet* and to harden the skin. In more concentrated solution it is used as a caustic for the removal of *warts, syphilitic condylomata, nasal polypi,* and other foreign growths. It has been highly lauded by Ganley (*B. M. and S. J.,* Oct. 14, 1920) in the treatment of *Vincent's angina.*

Although chromium oxide has not been used internally in medicine Kolipinski (*Monthly Cyclopedia of Pract. Med.,* Sept., 1908) asserts that *chromium sulphate* is a valuable remedy in the treatment of various chronic nervous diseases as *alcoholism, neurasthenia, locomotor ataxia, exophthalmic goiter,* etc. He administers it in doses of from one to eight grains (0.065–0.5 Gm.).

Those whose work brings them in contact with chromic acid or its salts, according to Hermann (*M. M. W.,* April 2, 1901), often suffer with lesions, the result of the local irritant action of these compounds either upon the mucous membrane of the respiratory tract or upon the skin. In a large number of cases there was ulceration of the nasal mucosa eventually with perforation of the septum while other patients developed *bronchitis, eczema, gastritis,* or other inflammatory disorders.

Dose, of chromium trioxide, should not exceed one-fourth of a grain (0.016 Gm.). It is very rarely, if ever, used internally.

Off. Prep.—Liquor Acidi Chromici, *Br.*

CHRYSAROBINUM. U. S., Br.

CHRYSAROBIN Chrysarob.

"A mixture of neutral principles obtained from Goa powder, a substance deposited in the wood of *Vouacapoua Araroba* (Aguiar) Druce (Fam. *Leguminosæ*)." *U. S.* "Chrysarobin is a mixture of substances extracted from Araroba by hot benzene. It consists of a definite chemical compound, $C_{15}H_{12}O_3$, also known as pure chrysarobin, or chrysophanolanthranol, associated with certain other substances of similar composition." *Br.*

Acidum Chrysophanicum Crudum; Araroba Purifié, *Fr. Cod.;* Chrysarobinum, *P. G.;* Crisarobina, *It.*

The British Pharmacopœia recognizes under distinct headings Crude Chrysarobin (Goa Powder or Araroba) and the Purified Chrysarobin. (See *Araroba.*)

The question of the chemical composition of chrysarobin is not yet completely solved.

Hesse (*Ann. Ch. Ph.,* 1912, p. 388) found that chrysarobin is a complex body containing at least five different substances, namely: *chrysophanol-anthranol,* its methyl-ether *emodinol* and its methyl ether, and *chrysarobol.* Of these chrysophanol-anthranol is the one to which the drug owes its characteristic properties. (See also Tutin and Clewer, *Tr. Chem. Soc.,* 1912.)

According to Eder (*A. Pharm.,* 1915, 1) chrysarobin yields on oxidation 0.2 per cent. of emodin, 32 per cent. of a methoxyl containing chrysophanic acid, 18 per cent. dihydro-emodin-anthranol-monomethyl ether and about 26 per cent. unidentified colored decomposition produtcs. Eder also found in chrysarobin free chrysophanic acid, emodin and methyl ethers of the latter; all partly in reduced form and partly as easily oxidizable *anthranols.*

Description and Physical Properties.—"A brownish to orange-yellow, microcrystalline powder. It is tasteless, odorless, and irritating to the mucous membrane. Chrysarobin is very slightly soluble in water. One Gm. dissolves in 385 cc. of alcohol, 30 cc. of benzene, 180 cc. of carbon disulphide, 13 cc. of chloroform, and in 160 cc. of ether, at 25° C.

"Chrysarobin dissolves in solutions of alkali hydroxides and in sulphuric acid, producing deep red solutions. On pouring the sulphuric acid solution into water, Chrysarobin is deposited unchanged. Mix about 0.002 Gm. of Chrysarobin with 2 drops of fuming nitric acid: a red-brown mixture is produced which becomes violet-red on the addition of a few drops of ammonia T.S. (*difference from chrysophanic acid,* which produces a yellow liquid). Boil 0.1 Gm. of Chrysarobin with 20 cc. of distilled water, and filter: the filtrate is neutral to litmus paper. Ash: not more than 0.25 per cent.

"Preserve in well-closed containers, protected from light." *U. S.*

"A light, microcrystalline, yellowish powder; inodorous; tasteless. Entirely soluble in hot *chloroform* and in hot *benzene,* almost entirely soluble in hot *alcohol* (90 per cent.), partially and sparingly soluble in *petroleum spirit,* almost insoluble in *water.* Almost entirely soluble in hot *solution of sodium hydroxide,* with production of a deep brownish-red color. Shaken with *solution of ammonia* the liquid slowly becomes violet. About 1 milligram mixed on a white tile with a drop of *fuming nitric acid* produces a brownish-red liquid, becoming violet on the addition of excess of *solution of ammonia.* Melts when heated, giving off yellow fumes. Ash not more than 1 per cent." *Br.*

Chrysarobin in alkaline solution takes up oxygen readily, even from the air, and changes into chrysophanic acid according to the reaction:

$$C_{30}H_{26}O_7 + 4O = 3H_2O + 2C_{15}H_{10}O_4$$

The difference in physical properties between chrysarobin and chrysophanic acid is well described by Andouard. (See *Proc. A. Ph. A.,* 1895, 864.)

Uses.—When taken internally in sufficient amount, chrysarobin acts as a decided gastro-intestinal irritant, producing large, very watery, brownish stools, and repeated vomiting without much nausea; it has, however, failed to secure a place as an internal remedy. Chrysarobin has long been used in South America and India as a remedy in skin diseases, but the attention of the general profession was first called to it in 1874 by Sir Joseph Fayrer. It is a remedy of the greatest value in the treatment of *psoriasis* and is also of service in chronic *eczema.* Schamberg, Kolmer and Raiziss (*Jour. of Cutaneous Dis.,* 1915, xxxiii) in an elaborate research on its mode of action reach the conclusions that chrysarobin is without germicidal properties and that its beneficent effects are probably due to its chemical affinity for the keratin elements of the skin, the drug abstracting the oxygen for its oxidation, which takes place simultaneously with this union, from the epithelium.

It may be applied in the form of an ointment with good success, although this method of application has the objection of staining the clothing. For this reason a number of dermatologists prefer the solution in collodion, which may be prepared by dissolving a drachm of chrysarobin in a fluidounce of the official flexible collodion. This is painted over the lesions with a camel's hair brush and after it is thoroughly dried the film may be coated with plain collodium as a further protection against staining the clothing. Another method of applying the drug is to dissolve it in chloroform in the proportion of one to two drachms to the ounce. This solution is painted on the skin, the chloroform evaporating and leaving a thin film of chrysarobin behind. Kossobudskji highly recommends in the treatment of *hemorrhoids* an ointment containing twenty-five grains of chrysarobin, nine grains of iodoform, and eighteen grains of extract of belladonna to the ounce of petrolatum. Benzin is said to be useful for removing the stains caused by chrysarobin.

Off. Prep.—Unguentum Chrysarobini, *U. S., Br.*

CIMICIFUGA. U. S.

CIMICIFUGA Cimicif. [Black Cohosh, Black Snakeroot, Macrotys]

"Cimicifuga is the dried rhizome and roots of *Cimicifuga racemosa* (Linné) Nuttall (Fam. *Ranunculaceæ*). Cimicifuga contains not more than 2 per cent. of its stems or other foreign organic matter, and yields not more than 4 per cent. of acid-insoluble ash." *U. S.*

Cimicifugæ Rhizoma, *Br.*, 1898, Actææ Racemosæ Radix; Cohosh; Macrotys; Rattleroot; Squaw Root; Rattle Snake Root; Bugbane; Rattle Weed; Richweed; Bugwort, Rattletop; Racine d'Actée à Grappes, *Fr.;* Schwarze Schlangenwurzel, *G.*

Cimicifuga was dismissed from the Br. Pharm., 1914.
